### THE NEW YORK LARYNGOLOGICAL SOCIETY.*

BY CLINTON WAGNER, M.D.,

PARIS, FRANCE.

IT has been twenty years since I last had the pleasure of reading a paper before the Laryngological Section of the New York Academy of Medicine, and I desire to express my appreciation of the compliment paid me upon this interesting occasion.

The celebration of the fortieth anniversary of the founding of the New York Laryngological Society was conceived by my friend Dr. Delavan, your former president, who for many years has been a most indefatigable worker in developing and uplifting the specialty of laryngology and rhinology; now he has rescued from oblivion the almost forgotten New York Laryngological Society and has placed its name on record in enduring bronze. I have been requested, as one of the early laryngologists in New York, to speak of the work accomplished by them, and will therefore ask your attention to a few words which I hope may prove of interest to members of the specialty.

Forty years ago the number of men in this city who were familiar with the modern methods of examining the throat and nose, could be easily counted. Most of us had received practical, or clinical, instruction in London, Berlin, Vienna, or Paris, but, notwithstanding, our knowledge of the diseases of the throat and nose was very limited. We could be compared perhaps, to young men fresh from the colleges or hospitals, with minds stored with the ideas of other men in the matter of the treatment of diseases, but with no fixed views, such as one acquires from practical and personal experience when called upon to think and act for one's self. In other words, our knowledge of the throat and nose had taken no concrete form; had not crystallized; for we had no blazed trail to follow through the intricacies of this department of medical science. We met one evening at my house, in October, 1873, and decided to organize a society, not only for mutual improvement and the advancement and enlargement of our limited knowledge of the diseases of the throat and nose, but we had also in view establishing on a solid footing with the medical profession at large the specialty of laryngology and rhinology in this country, for the reason that many of the physicians of the time looked askance upon all specialties. The general practitioners in medicine and surgery were jealous of interlopers; the probang and gargles were their sole reliance for all cases of sore throat; the nose was ignored.

*An address at the fortieth anniversary of the New York Society of Laryngology, New York Academy of Medicine, Tuesday, November 25, 1913.

The aurist, who preceded us, had had his troubles in obtaining recognition; in fact, the physician who undertook to cure chronic deafness was regarded as a charlatan. A surgeon in one of London's largest and best known hospitals, but a short time prior to the date to which I have referred, during the course of his lectures coming to the subject of the ear, dismissed it curtly by asserting that there were but two classes of ear trouble or deafness, those that could be cured with the syringe and those that could not, and for the latter nothing could be done.

All of us who met on that evening in October were connected with clinics for the diseases of the throat. At subsequent meetings, we sent cases of special or unusual interest, which were examined and discussed by those present, all of whom were young, hard-working, ambitious, and determined to make successful careers during the coming years in this the largest city in America and destined to become the largest in the world. Not all of them continued to follow the specialty; those who did succeeded to the full measure of their expectations, and always stool first among laryngologists; they were George M. Lefferts, Francke H. Bosworth, Morris J. Asch, Woolsey Johnson, and Norman D. Bridge. The two latter died young.

The others. Charles McBurney, Robert F. Weir, Matthew D. Mann, Francis P. Kinnicutt, sought a broader field for their abilities in general surgery or medicine, but all, before many years had passed, became well known throughout the entire country, and no word of praise from me can add to the luster of their fame.

Many young men came to our clinics for instruction. I had patients from various parts of the country and Canada, but from the Potomac River to the Rio Grande, there was absolutely no one to whom I could refer my patients for further treatment at their home towns or cities. However, the specialty became popular, not only with the laity but also with the profession, which at first had given it the cold shoulder. The laity soon learned that many ailments of the throat from which they had suffered could be speedily relieved by those physicians familiar with the more modern methods of treatment, and the profession seemed content to refer cases which they could not handle, to those who could.

As an evidence of the rapid growth and popularity of the specialty, within less than five years after the organization of this society, it was deemed advisable to have a national society; accordingly the American Laryngological Association was organized at Buffalo in 1878, with a membership limited to fifty, but within a few years the number was increased to seventy-five and later to one hundred, as at present. In the nineties a sister society was organized, the American Laryngological and Rhinological, with a large membership roll.

As I have stated, the laity took kindly to the specialty when they learned, as they soon did, that relief was afforded speedily in many cases of laryngeal and pharyngeal ailments, which had resisted all ordinary treatment, and the profession showed a disposition to refer those cases which they were unable to diagnosticate.

For instance, adenoids and enlarged tonsils were not suspected as a cause of habitual mouth-breathing; the etiology of hoarseness and aphonia was not recognized; and dyspnea was not infrequently ascribed to and treated as asthma, when dependent upon stenosis of the larynx caused by neoplasms or upon nasal obstruction.

During the two years I spent abroad in acquiring a knowledge of the specialty, the treatment of nasal troubles was practically ignored by those who taught; of course, polypi, foreign bodies, and tumors were recognized and removed, but there was no systematic instruction given for nasal troubles, as for the larynx and pharynx.

The prevalence of chronic rhinitis or so called nasal catarrh in our country, stimulated research into the hidden labyrinths of the nose, and in this branch of the specialty we went rapidly ahead of our confreres on the other side of the Atlantic.

In contrast with the comparatively friendly reception accorded to the early throat specialists in this city forty years ago, let me recall the hostility, less than a generation before, that was encountered by Dr. Horace Green, a man whom the profession in America to-day appreciates and justly honors. Dr. Green was the first throat specialist in America, and the *first in the world* to demonstrate that an instrument could be introduced into the larynx through the rima glottidis into the trachea, and as far as the bifurcation of the bronchi. He used a sponge probang charged with a strong solution of nitrate of silver for the treatment of the larynx, and by means of a catheter introduced solutions into the bronchi, for the relief or cure of certain pathological conditions.

Much opposition to his views and claims of being able to do this was encountered in the profession; a committee of the Medical and Surgical Society of New York condemned his theories and practice, and even a professor of anatomy declared his claim impossible. Dr. Green was asked to withdraw from the society.

His work on "Polypi of the Larynx and Edema of the Glottis," showed that he was far in advance of the age in which he lived; he not only diagnosticated the presence of laryngeal growths but successfully removed them by means of laryngotracheotomy.

If the laryngoscope had not been discovered as an aid to diagnosis, there would nevertheless be to-day throat specialists following the methods and teachings of Dr. Horace Green. To the laryngoscopist who removes without difficulty growths from the larynx and makes topical applications with the aid of the mirror, the brilliant work of Dr. Green appeals most strongly.

I have endeavored in this brief address to set forth the good work accomplished by the early laryngologists in establishing the first laryngological society in the world; "they builded better than they knew," and, as a tree is known by its fruit, so will the work of these pioneers be appreciated and understood, when we look upon the scientific work now being performed by the Laryngological Section, under the sheltering ægis of the Academy of Medicine.

## LARYNGOLOGY IN NEW YORK.*

By D. BRYSON DELAVAN, M.D.,

NEW YORK.

We have met to commemorate the fortieth anniversary of the New York Laryngological Society, the first society of Laryngology ever established, at least in modern times, in this country or in the world.

While eulogizing the society we are also accorded the great privilege of offering our tribute of honor and appreciation to its modest but far-sighted and public-spirited founder, Dr. Clinton Wagner, the guest of the evening, and to those other enthusiastic spirits who associated themselves with him in the society's primal organization.

It is well that we ourselves, as men loyal to the medical profession of the country and justly proud of the city in which we live, should fearlessly claim for New York the credit for intellectual and scientific eminence which through many generations its physicians have so richly deserved. It is well that we should know something of the lives of those pioneers whose toilsome struggles and rare genius have brought to us who have come later so many and so great advantages and that we should realize the far-reaching influences for good which have steadily grown from their high-minded and unselfish efforts. Finally having glanced at the conditions which led to the formation of the New York Society of Laryngology it is well that we should at this time recount the story of what New York has done for laryngology and study the exploits of the men who have contributed in so many wonderful ways to its fame.

Long before the invention of the laryngoscope it was here, in the city of New York, that attention was first seriously turned to the special study of diseases of the throat; here, that the most important principle connected with the physiology of the throat was first discovered; here that the possibilities of the topical treatment of the larynx were first demonstrated, developed, and perfected; here that intralaryngeal surgery had its birth; the first public throat clinic in America, and perhaps in the world was established here; here the causes of nasal obstruction were first understood and successfully treated and the way thus opened for the recognition and treatment of sinus disease; here that intubation, with all of its great possibilities, was first made practicable; here that Koller, abandoing Europe, taught the value of local anesthesia and gave us cocaine; and here, again, in the city of New York, that was founded the first Society of Laryngology in the world.

With regard to the founding of the society it must not be supposed that this event was in any sense accidental. On the contrary, it was the culmination of more than a century of blind struggle, of earnest groping for the light, and while progress was tedious and slow, there was, nevertheless, a constant advancement of which this was the successful, the triumphant, issue.

A hurried history of the situation would be instructive, for, did time permit, the story of the early study of disease of the throat in America is not without interest. Suffice it to say that the first mention of throat disease, probably an epidemic of diphtheria, was made by Captain Morton in his

*An address delivered in commemoration of the fortieth anniversary of the founding of the New York Laryngological Society, at the New York Academy of Medicine, November 25, 1913.

"New England Memorial," in 1650, while Josselin, about ten years later, in "An Account of Two Voyages Made to New England" mentions another epidemic of similar character.

During the following 200 years progress was very slow, until toward the close of the period, when the subject began rapidly to receive considerable and increasing attention.

In 1846 Horace Green, already spoken of by the guest of the evening, presented his "Treatise on Bronchitis," the result of work begun by him in 1838.

In this extraordinary thesis he first described what he called "Catheterization of the Larynx." Under this unpretending title he announced the great discovery that a foreign body could be introduced into the larynx and even below the vocal cords without necessarily producing suffocation.

For this all-important discovery credit is beyond question due to Green. That his suggestion as to the value of local applications to the larynx in general and, in particular, of nitrate of silver were worth while would seem to be proved by the fact that in the Vienna clinics and elsewhere silver was the main reliance for more than a generation. Strangely enough, and as if in confirmation of the justice of this, argyrol to-day is one of our most popular remedies.

Horace Green's thesis was destined to produce a revolution in the treatment of laryngeal disease and to open the way for new methods, both medical and surgical, which have constantly increased in number and in value from that time up to the present day. Perhaps no more interesting and, from a practical point of view, more important addition has ever been made to our knowledge of physiology than the principle discovered by him, that the larynx would tolerate the presence of a foreign body.

To the name of Green must be added that of another citizen of New York, Dr. Gurdon Buck, who has been called the father of laryngeal surgery. In 1848, when Green was doing his own best work, Dr. Buck published a series of classical papers upon "Edema of the Larynx," in which he taught the diagnosis of these cases by palpation and devised a special knife which, safely guarded by the forefinger of the examiner, could be passed into the larynx and applied with successful effect. Thus did our city, far in advance of the world, produce the two most successful and epoch-making students of the larynx of prelaryngoscopic days.

The grand epoch in the history of laryngology, however, was rapidly approaching. As we have already shown, much attention had already been given to the study of diseases of the throat and as Dr. Wagner has well said, in the able hands of such men as Horace Green, laryngology would have taken its place among the special branches of medicine, even if the laryngoscope had not been invented. But a wonderful thing was to come to pass. In the words of the well-chosen motto of the American Laryngological Association,

*"E tenebrae lux."*

Out of darkness was to come the light, and the regions of the larynx hitherto obscured were now to be made visible to the eager searchers after truth.

In 1858 the dawn ushered in by Horace Green, was made brilliant daylight by Manuel Garcia's invention of the laryngoscope and the way prepared for the establishing of the specialty upon a definite and firm basis. Here, again, New York took the lead, at least in this hemisphere, for it was the distinguished and much respected Dr. Ernest Krackowitzer, surgeon to the New York Hospital, who was the first in this country to procure a laryngoscope from Vienna and with it, in 1858, to demonstrate the vocal cords.

Great events are apt to move slowly. It was not so with the development of laryngology. Following the announcement of Garcia's invention and Czermak's and Turk's appreciation of it, a clinic was established in Vienna by Turk to which many students resorted for instruction in the new art. Soon other clinics were started in Vienna and Paris, and later in London and Berlin, the most noted of them being under the direction of Tobold of Berlin, von Schrötter of Vienna, Mackenzie of London, and Fauvel and Krishaber of Paris. Of the opportunities offered by them progressive young Americans were not slow to take advantage, for in that day contrary to what is now the case, if laryngology was to be learned at all, it was necessary to go abroad to study it. Among these early students were the founders of our society.

Dr. Wagner has already told us of the conditions which prevailed soon after the return from Europe of the men who were his student companions there and of the desire of himself and others to make an organized effort for the establishing and promotion of the specialty of laryngology in this country.

But the success of that effort was not confined to New York. Five years after the organization of the New York society, able laryngologists were to be found in most of the principal cities of the Northern States. So great was the increase that, following Dr. Wagner's original intention, in 1878, a national society, the American Laryngological Association, was founded.

Meanwhile, as compared with ours, what had been the progress of the outside world in this direction? The British Laryngological Association was founded by Sir Morell Mackenzie in 1888, ten years after ours and not until fifteen years after the New York society. The associations of France and Belgium were begun in 1890, that of Italy in 1892; Holland in 1893; Scandinavia, Russia, Germany, Austria and Spain being at that time not represented.

In addition to its scientific and social purposes there were important ethical reasons for the existence of the new society. About that time a number of men, chiefly from Europe, had come to this city and had announced themselves as specialists, several of them advertising extensively in the public press. A few claimed to have received regular instruction in European clinics. Many, on the other hand, were not even graduates in medicine, and it had become necessary that some acknowledged standard should be raised for the protection of the public.

Among the best of the newcomers was Dr. Sass, who made his home in New York. He was a man of quiet life and demeanor whose contributions to the armamentarium of the specialty were ingenious and valuable, notably his modification of the spray atomizer which superseded the use of the laryngeal brush, as the brush had superseded the probang and revolutionized the method of making applications to the throat.

The Americans, on the other hand, who entered the department of laryngology in those early days, were men of the highest type. Not a few of them had seen service during the War of the Rebellion,

either as members of the Medical Corps of the army or in regular service. The New York Society of Laryngology numbered at least four of these. Chief among them was Dr. Wagner, whose war record is an eloquent tribute to the courage and efficiency of the man. Entering the Medical Corps in 1860 at the beginning of that great conflict he served with distinction until its close. He established numerous hospitals, among them the first floating hospital on Western waters. He was Surgeon-in-Chief of the Regular (or 2d) Division of the 5th Corps of the Army of the Potomac. At the battle of Gettysburg his hospital was the one nearest to the firing line and, in the desperate attempt of the Confederates to retake Little Round Top was in the midst of such a hot fire of shot and shell that it became necessary to abandon it for a less exposed position. As everyone knows, the fighting around Little Round Top was one of the most terrible incidents of the Civil War. As the outgrowth of his opportunities during those stirring years Dr. Wagner had a rich surgical experience before he was twenty-five.

Dr. Asch also saw service as an army surgeon.

Dr. Lincoln enlisted when a Junior at Amherst College, entering as second lieutenant, and rising rapidly to the colonelcy of the 37th Regiment, Massachusetts Volunteers. He was severely wounded while leading his troops in no less than three engagements, once by a rifle shot in the thigh, again by two severe saber cuts in the forehead, and, finally, by a shot through the right lung, received so near the close of the war that he was mustered out, with the rank of Brevet Brigadier General, before sufficient time had elapsed for him to resume active service.

Dr. Bosworth had a short term of service in the Northern Army.

I call attention to this phase of the life of the time because by reason of it extraordinary opportunities were given for the development of strong traits of personal character, and in the medical service for unlimited opportunity and experience in medical as well as in surgical work. The men who entered laryngology, moreover, were generaly of good position and excellent education, possessed of fine intelligence and able to afford the means for securing the best special training. They realized the value of the new specialty as a field for scientific investigation and for practical work. Of highly trained power of observation, untiring clinicians and diligent readers, they relied upon the experience gained by such means rather than upon the not always infallible findings of the laboratory. They were also enthusiastic teachers. No wonder that their pupils were inspired with a little of the leaven which they so freely gave. No wonder either that we who had failed to enjoy some of their advantages, notably that of military life and discipline, found it hard to emulate them.

Following the organization of the society, its membership increased with rapidity, and in the course of a few years a goodly number of ardent workers had come to the front. The specialty was new, everything was to be done and learned, and rhinology had not been born. True, rhinoplasty had flourished for generations under the lead of the Italian surgeons. In this field Dr. Gurdon Buck, of New York, was prominent. Efforts were directed to the correction of external deformities of the nose by means of sliding skin flaps. Corrections of bone deformities were seldom attempted.

About 1880 Prof. T. C. Sabine, of New York, attempted to restore a nose by transplanting the middle finger of the patient to the open space. The transplantation was successful, but the exchange was startlingly evident to the eye. Indeed, the effect was so hideous that the patient was shunned by his friends, and, becoming despondent, shot himself. What would have been the surprise and delight of these two great surgeons, Buck and Sabine, if they could have seen the admirable series of cases of nasal repair presented at our last meeting by the chairman of the section, Dr. Carter.

As before stated, rhinology in the early seventies was unknown. Attempts were made to treat nasopharyngeal catarrh, but beyond that and the surgical treatment of polyps and growths and the control of epistaxis, little was done. Nasal obstruction was not understood and the causes leading to it were practically unrecognized, although Catlin in a very interesting work, had called attention to "Mouth Breathing" in 1853, and Clinton Wagner had presented an admirable thesis on the same subject, as related to medicine, in 1881. The clinics of Europe and many of our own were in the habit of grouping the affections of the nose in general under the head of "nasal catarrh" or "chronic rhinitis." The surgery of the septum and of the turbinated bodies did not exist. The nasal sinuses, except anatomically, were unknown.

It was Dr. William C. Jarvis, a member of the New York Society, who first recognized and called attention to the importance of nasal obstruction due to undue swelling, or chronic hypertrophy, of the turbinated bodies, and it was he who devised that most ingenious of all instruments for correcting the difficulty, the so-called Jarvis snare. It was Bosworth who recognized the part played in nasal obstruction by nasal spurs, and who was the first to advocate their removal by means of the saw.

It was another member of the New York Society, Goodwillie, who substituted for Bosworth's saw the dental engine for the carrying of trephines and burrs, and again another member, Asch, who recognized the inadequacy of the efforts made by Adams and others to repair deformities of the nasal septum and gave us the first practical method for their relief, a method which, with its modifications, still holds a position of much usefulness, in spite of newer and less conservative means.

Finally, although not of New York City, we have within New York State Dr. John O. Roe, whose wonderful originality and ingenuity and unrivaled technical skill in repairing nasal deformities in general have caused him to outrank all others, either in this country or abroad.

While on the subject of the nose, we must not neglect the great work of Lincoln in the treatment of nasopharyngeal fibroma.

He it was who, following and elaborating the suggestions of Voltolini applied electrolysis and the use of the galvanocaustic snare with successful results in the removal of these growths, with practically no loss of blood and with a minimum of shock, whereas the fatality from hemorrhage in the course of the removal of the tumor and from the shock of the preliminary operation under the old surgical methods had been enormous, many patients dying on the operating table. By Lincoln's method, preliminary operation was dispensed with, the operation being carried on through the natural passages, hemorrhage was avoided, shock was inconsiderable, and the possibility of recurrence was immeasurably decreased.

As a therapeutist also Dr. Lincoln was original

and wise. His combination for coryza is classic and in general use to-day.

Upon the merging of the New York Laryngological Society with the New York Academy of Medicine Dr. Lincoln was elected fiirst president of the new section.

One of the most interesting inventions that laryngology has produced was made by our distinguished colleague from Brooklyn, Dr. Thomas R. French. Lennox Browne, of London, had succeeded in photographing by time exposure the larynx of a singer who could demonstrate his own remarkable tolerant throat.

By the method of Dr. French, for which he devised a special camera, any larynx or upper pharynx that could be demonstrated at all could be photographed, and that by instantaneous exposure.

Thus a new and effective resource was provided for the study of the physiology and pathology of the upper air passages and many new facts were developed upon the subject of the production of the voice. Indeed, with the advent of French's camera and the phonograph of Thomas Edison, New York placed the study of voice production for the first time upon a genuinely scientific basis.

French's adjustable table, for securing the upright position of the patient in the removal of adenoids and for other operations upon the throat and head, perfected within the past year, is the most admirable device of its kind yet invented.

Again referring to O'Dwyer of New York, no man of loftier character or more far-seeing intelligence was developed in our generation. His method of intubation for the relief of laryngeal obstruction in diphtheria was one of the most remarkable exploits in the history of surgery and was recognized by him as being applicable in many other and widely different conditions of laryngeal disease and injury. Thus, in addition to diphtheria, he applied it to obstruction of the larynx due to acute diseases, to injuries and lacerations of the soft parts, and to fractures of the laryngeal cartilages. He employed it with success in cicatricial contractures of the larynx and his methods, in this class of laryngeal deformity, elaborated by the modifications suggested by John Rogers, of New York, have proved far superior to any that preceded them and are unquestionably better than those of European device that of late years have been offered to us.

In the literature of laryngology New York has always maintained a leading place. Following the introduction of the laryngoscope a number of works appeared in Europe which were of greater or less value. It remained for three English-speaking authors to present complete treatises upon the subject of laryngology and rhinology. These were J. Solis Cohen, of Philadelphia; Sir Morell Mackenzie, of London, and Francke H. Bosworth, of New York. These thoroughly comprehensive works exerted a final influence in the establishing of the specialty throughout the world that has never been equaled. Meanwhile, among the other writers of the day, Beverley Robinson, Elsberg, Wagner, were eminent. All of the leading men of the time were doing excellent original work and freely recording their results. What they accomplished would have been worthy of all credit had it ended with them. But through us who came under its influence, and through those who in turn have been our pupils, it will live and flourish, let us hope, for many generations to come.

Again taking the lead in America, Dr. Elsberg, of New York, published a bibliography of laryngology in the United States, dating from the earliest records to 1875. In the same year, 1875, Dr. Lefferts began to publish monthly a complete report of the current laryngological literature of the world. This was carried on by him for a number of years and later was taken up without interruption by the "Index Medicus," where it is still continued.

Of the whole amount of laryngological literature of the world the United States contributes 25 per cent. New York's share of this is large and of very superior excellence.

The list of our fellow-members who, following the earlier names, have contributed to the fields of invention, investigation, and literature in laryngology is long and distinguished. Even to refer to all would be difficult. The section has reason to be proud of the records of such men as Jonathan Wright, Park, Gleitsmann, Simpson, Coakley, of the much beloved Knight, and Newcomb, both so lately gone from us, not to mention scores of others whom we hold in warm admiration and respect.

Of teachers New York has produced and is still producing a splendid array, many of whom have attained highest distinction, both in the departments of graduate and of undergraduate instruction.

Dr. Wagner established the Metropolitan Throat Hospital and made it a model institution, which soon became famous among those desiring advanced instruction. This hospital was well in the lead with regard to the observance of cleanliness in the handling of patients. Scrupulous care was observed to safeguard the patient by all the means then recognized. Foreshadowing the introduction of aseptic methods, it was the best managed clinic of its time. Unfortunately, this could not be said of all dispensaries for the treatment of diseases of the throat. In many abroad and in some at least here at home the conditions were not good, and, compared with modern methods of asepsis, they were in some respects incredibly bad. Why patients were not infected by the means used for treating the milder conditions of the throat must be explained upon the theory of the germicidal power of the nitrate of silver and of iodine, the most frequently employed remedies of the time. In the case of the more serious infections, however, great care was generally used to observe every known precaution.

Wagner, besides organizing a model clinic and hospital, showed great inventive genius. His nasal forceps was among the earliest instruments of its kind, and is still one of the best. He modified the old-fashioned powerblower so that it could be conveniently attached to the compressed air apparatus.

His great experience as a general surgeon and his rare technical skill enabled him to attempt with success operations upon the throat which few specialists were in the habit of undertaking. This statement is proved by the published record of his cases of thyrotomy, which for skill and execution, originality of detail and successful result have not been surpassed.

As a consequence of these advantages his clinic was sought by the most discerning pupils of the time, many of whom were destined to advance to positions of eminence.

According to the statements of the late Dr. Louis Elsberg, he himself was the first to lecture on laryngology in the United States. He began in 1861 and in 1863 he established a laryngological clinic at the University Medical College. Dr. Els-

berg claims that this was the first public clinic in America, and perhaps in the world. This present year, 1913, marks its fiftieth anniversary, and, not to mention the vast amount of work done in the other cities of the United States, finds New York City alone with sixty clinics for the treatment of diseases of the throat.

As one of our earliest instructors of graduates, Dr. Wagner deserves first rank. As an instructor of undergraduates, another one of the charter members of our society will long be remembered as having far surpassed any of his masters of the Old World. The lectures of Dr. Lefferts, continued for many years at the College of Physicians and Surgeons, have never, as far as I have been able to learn, been equaled.

So the story of what the New York Society has done for laryngology might be continued through many chapters. If the aims of its organizers were ambitious, they were also eminently high-minded. How they have succeeded the brief and imperfect suggestions which I have tried to give you, added to your own knowledge of what has been done in more recent years, will amply prove. Its earliest members, Wagner, Lefferts, Bosworth, Asch, were probably, with few exceptions, either your instructors or [illegible] or the ones from whom your instructors derived their chief inspiration. As such we accord to them the honor which they so richly deserve, and, in many instances the warm affection which their sympathy and helpfulness to us as beginners in a difficult career have called forth.

In the history of the society the fine altruism of Medicine at its best and most dignified has been splendidly shown.

The great discoveries and inventions of its members were not hoarded for the purpose of personal gain, but were freely and enthusiastically given to the profession and to the world, with the freest liberality and the most broad-minded and philanthropic spirit. The idea that salvarsan could be patented had not occurred to their unsophisticated minds.

The history of the society since it became the section on laryngology of the Academy of Medicine, itself the first and best institution of its kind in the world, is too recent to warrant my bringing it before you to-night. Suffice it to say that it has thus far well sustained its traditions.

Those who have been its members have been earnest and in many instances brilliant men, whose work has sustained the high standards of the past. Its present is most satisfactory and the promise of the future was never more bright.

It is my strong and earnest desire to excite and foster a lively interest in the history of our specialty in this country.

That a knowledge of what has been done in the past by others may at any time be productive of most valuable results to ourselves has been frequently shown. Thus the work of Professor Langley, in the invention of the flying machine, although apparently a failure, was turned to brilliant success by the introduction of the motor engine. A given work of the past may have fallen short of success simply for the lack of some element which has in later years been supplied. This idea has been beautifully illustrated by the evolution of the bronchoscope. It may surprise some of you to hear that we of New York may claim no inconsiderable share of the credit for this wonderful invention, as will be seen when we remember the principles upon which it depends. These are the tolerance of the larynx to the introduction of a foreign body, the insertion into it of a tube capable of dilating it to its greatest extent and the introduction through this tube and into the deeper parts of the air passages of a powerful light. The tolerance of the larynx to the passage of a foreign body was first definitely established by Horace Green of New York; O'Dwyer of New York demonstrated that the larynx would retain a dilator for an indefinite length of time. He, himself, also devised a tube for the express purpose of facilitating the expulsion of foreign bodies from the trachea, thus propounding the grand fundamental idea of the instrument. Acting upon this suggestion, Coolidge of Boston lengthened the O'Dwyer tube and illuminated the trachea through it with a strong reflected light. The great Thomas Edison of New York had invented the incandescent electric lamp and this had been modified in the form of lamps of small size of several candlepower, capable of being used in the exploration of various cavities of the body. To adapt this principle of examination to the method of Coolidge and of Mosher, also of Boston, was comparatively simple, and when Kirstein and Killian had exhausted their ingenuity Chevalier Jackson, another American, set his brilliant mind upon the matter and gave the world the perfected bronchoscope.

Again, the fact that an invention or an idea is old is no proof that it is necessarily inferior to something more recent. On the contrary, many an old method has been superior to the ones which have taken its place and its abandonment has been a step backward and a distinct loss.

There are always those who will say: "Of what use is a knowledge of the past?" "Why should I waste time upon it when the present holds out so much to me, and the future is beyond?" No thinking man can satisfy his mind with this sentiment, as the history of the development of the bronchoscope proves. We can know of no way of judging of the future, or, indeed, of truthfully understanding the present, but by the past. And knowing the past and guiding ourselves by it, how many successes might we emulate, how many failures avoid? History instructs and warns. Tradition, the outgrowth of history, dignifies, while, fostered by tradition, sentiment stimulates us to action and inspires us to high aims.

One of the chief objects of this meeting is to arouse in the members of the society, present and to come, a lively interest in the work of the past. To that end we have tried to give not only the record of its origin and its early career, but to place in the permanent keeping of a strong and enduring institution certain definite reminders of the past of laryngology in America and in New York. These things might have been deposited elsewhere, but there is no city where they so rightfully belong as in New York, and no institution likely to better utilize and appreciate them than the Academy of Medicine.

This tablet, which I have taken great satisfaction in preparing for you, has been accepted by the Trustees of the Academy of Medicine and approved by the members of the section in laryngology and rhinology in regular meeting. I place it in your safe keeping with full confidence that it will fulfil its intended mission. May it arouse in us and in those who shall come after us a desire for full and

thorough knowledge in all that pertains to our chosen field of professional work; may it add to our enthusiasm and respect for this great metropolis of which we are citizens; may it stimulate a just appreciation of American medicine and a high ambition to forever keep it by superior ability, by superior energy, and, far above all, by superior integrity, in the forefront of the progress of the world.

40 East Forty-first Street.

## UNRESOLVED PNEUMONIA.*

By JOHN S. THACHER, M.D.,

NEW YORK.

If we are to believe some eminent medical men, this matter lies more in the domain of mythology than pathology. Members of my house staff show the effect of such teaching, and occasionally inform me that there is no such thing as unresolved pneumonia, what is so called being either empyema or tuberculosis.

On the other hand, many leading medical authorities assert with no appearance of doubt or mental reservation the occasional long delayed resolution of pneumonic consolidation.

In Flint's "Practice of Medicine," the edition of 1873, there is a definite clinical picture of cases which had come under his observation and had gone on to the recovery which confirms the diagnosis.

Osler, in his "Practice of Medicine," reports forty cases at the Johns Hopkins Hospital, being between 3 and 4 per cent. of all their cases of pneumonia. These cases were studied by McCrae and included two which came to autopsy and showed in the fourth and ninth weeks persisting inflammatory consolidation. In one of Osler's cases nearly the whole of the left lung was solid for eleven weeks and then cleared perfectly. Musser and Norris, collecting over 2,500 cases of pneumonia, report delayed resolution in more than 4 per cent. The diagnosis in these cases was not, however, carefully scrutinized. Strümpel, Allbutt, Powell and Hartley, and Holt teach similar doctrine.

In view of these contrary opinions I have long wanted to review the experiences of the two hospitals with which I am connected, and see whether I could thus get any light on this interesting subject. Therefore in response to our secretary's insistence I decided to look over the recent cases of pneumonia in the records of these two hospitals and report on them to-night.

With the very kind aid of recent members of the house staffs, a list has been prepared for me of 1,252 cases of pneumonia observed during the past few years, with certain statistical data.

The cases running prolonged courses I attempted to analyze, but time has been too short for me to go carefully over more than the first 200 cases. I will therefore give only an informal and partial report to-night, hoping later to publish a more complete and formal analysis of the larger series.

In only two of the 1,252 cases was the diagnosis of delayed resolution entered on the discharge card, showing the effectiveness of the prevailing teaching. However, in the 200 cases which I have been able to look over with some care, I find 34 in which the fever ran for three weeks or more, *i.e.* 17 per cent.

Of these there were 14 cases in which the prolonged run of fever was so moderate, though lasting into the fourth week, and the condition so mild, that the cases, even if they were possibly true instances of unresolved pneumonia, were of little clinical importance, except to teach us that such a delay in recovery, if the other symptoms are mild, is usually followed by perfect restoration of health.

Of these 14, nine simply ran a trailing fever maintaining a daily maximum of 100° till the twenty-third to the twenty-sixth day. In three of these there was an early period of normal temperature, followed by a return of the fever. Two did the same till the twenty-ninth and thirtieth days. One after a normal period ran a temperature with daily maximum of about 101° till the thirty-sixth day. One showed a moderate elevation of temperature from the thirty-first to the thirty-fourth day, and one presented five isolated shoots of fever between the sixteenth and thirty-ninth day. In all of these 14 there was no apparent cause for the late recovery and in all the lungs afterwards seemed to be perfectly sound.

Among these 34 cases of prolonged fever there were, besides these mild trailers, 6 with miscellaneous complications, otitis media, gastroenteritis, evident tuberculosis, etc., to explain the continuance of elevated temperature.

There were, moreover, 9 cases of empyema or abscess, and, which interest us particularly, 1 case of delayed resolution with abscess, 1 probably delayed resolution with abscess, and 3 probably simple delayed resolutions. Put into tabular form, in 200 cases of pneumonia there were 34 with fever lasting three weeks or more. Of these there were:

Fourteen simple mild trailers with recovery.
Six with miscellaneous complications.
Nine empyema or abscess.
One delayed resolution with abscess.
One probably delayed resolution with abscess.
Three probably simple delayed resolution.

This small series of cases then tends to indicate this chief conclusion, that of patients, who after pneumonia are quite ill with a prolongation of fever, more are suffering from the presence of pus, in the pleura or the lung, than from any other abnormal condition.

But on the other hand many mild prolongations of fever occur without serious import, and among the cases with prolonged high fever there are some which clear up without manifestations of suppuration or tuberculosis and are probably instances of simple delay in the resolution of pneumonic consolidation.

Of the five cases which were apparently delayed resolution of marked type, only one came to autopsy. The patient died on the twenty-third day, and both lower lobes were found to be solid, a typical exudate, such as is characteristic of lobar pneumonia, filling the alveoli. There was also some interstitial inflammation, and a small abscess.

A second patient was in the hospital until the fortieth day, when she insisted on going home. The fever persisted all of this time. On the sixth day, however, it had come down to about 100°, but then rose higher until the thirty-first day, when for a few days it stayed below 100° and the patient felt well except for the cough. It rose again, however, about the thirty-fifth day with a widely swinging temperature, and a maximum of 104°, and a few days later she went home. On the thirty-second day, when the temperature had become normal, the leucocytes were also normal, having come down from 15,000. When the temperature rose during the last

*Paper read at the 256th regular meeting of the Practitioners' Society of New York, October 10, 1913.

week in the hospital the leucocytes rose again to 19,000, but not the percentage of polynuclears. The signs did not clear up. They changed so as to be like signs of fluid, but the chest was explored with the needle nine times without finding any. The sputum was examined twelve times for tubercle bacilli, but none found. On each occasion pneumococci were reported present in the sputum. A von Pirquet test was negative. Towards the end of her stay in the hospital the sputum became more abundant and purulent. A radiogram now showed a triangular shadow at the right of the mediastinum with its base on the diaphragm. This case certainly seems to have been one of delayed resolution with development of an abscess at the end of the fifth week.

The third patient, aged 38, reached a normal temperature on the nineteenth day, but up to his discharge on the twenty-second day the signs of consolidation persisted although he was otherwise perfectly well.

The fourth patient, aged 6, showed on admission signs of consolidation at the apex of the lower lobe and dullness below. A few days later it was noted that dullness at the base was marked, with diminished vocal resonance and respiratory murmur. No egophonic quality to the voice anywhere. Up to the twenty-fourth day there was a regular high intermittent temperature coming down to normal on the twenty-fifth day and staying there. The leucocytes were 36,000 on admission and remained above 20,000 until the thirtieth day, although the polynuclears had come down by that time from 80 per cent. to 61 per cent. On the thirty-ninth day the child was discharged cured, and the signs had disappeared. In this case one cannot say positively that there were no complications; very likely there was more than the usual amount of pleural exudate, but the spontaneous recovery would indicate that there was no serious complication, and one may say that practically speaking it was a case of delayed resolution.

In the fifth case, a man of 54, the signs of consolidation continued and their extent increased up to the twentieth day. Even on the thirty-sixth day faint signs could be heard over part of the same area and over a very small spot up to the forty-seventh day, when he was discharged "cured." The temperature ran a varied course, at first high with a crisis on the seventh day. Then it rose gradually to 105° on the nineteenth day. By the twenty-eighth day the daily maximum had fallen to 100.5°. There was another brief upward wave, but then it stayed most of the time below 100° until his discharge. His leucocytes were highest on the eighteenth day, 26,000; on the thirty-seventh day still up to 13,000. The percentage of polynuclears, which were counted five times, the last time being on the thirty-seventh day, was never below 81. The sputum was examined four times for tubercle bacilli with negative results. The von Pirquet was positive. On the twenty-sixth day the needle was inserted twice without getting fluid. Some months later he returned with consolidation of the right lung, a small area of which could still be detected on the eighteenth day. On the thirtieth day he was discharged cured, the lungs having entirely cleared up.

In this case, the long continuance of fever, signs, leucocytes, and polynucleosis, followed by complete spontaneous recovery, with a repetition of the same, though more brief, later, in another part of the lung, certainly leads to the conclusion that there was a delayed resolution and no important complication.

We have then five cases among these 200 pneumonias in which it is reasonable to believe that there was a serious delay of resolution.

Another case shows how extension of the pneumonic process may greatly prolong the febrile course. This patient, a boy of about 5, on admission had signs of consolidation of the upper lobe, on the twelfth day of the right middle, on the eighteenth day of the right lower lobe. His temperature, which had been very high, reached 100° on the twenty-second and reached normal on the twenty-seventh day. All physical signs had cleared up on the thirty-first day. On the twenty-first and twenty-second days five explorations were made with the needle without obtaining any fluid.

As suppuration in the pleura or in the lung is not an infrequent event after pneumonia, and as it is most important to remove the pus if it is there, it follows that we ought if possible to find the means of recognizing its presence, and especially of distinguishing it from delayed resolution.

Physical signs are not infallible in differentiating fluid from consolidation. The classical signs of fluid may be present when there is only consolidation, and v ce versa. Especially difficult may be the recognition of fluid when it is in a small pocket, when an area of consolidation adjoins it, or when it is buried in lung tissue. All of these circumstances are frequent in cases of pneumonia. If there be a large accumulation of fluid free in a pleura the usual rules of physical diagnosis will generally give a correct answer, but not always. Especially helpful, as Morse has pointed out in the case of children, will then be the marked sense of resistance on percussion and displacement of the heart. But in interlobar or other encapsulated empyemas or pulmonary abscesses these points may not be present.

Some writers extol the helpfulness of local friction, local edema and pain on pressure in detecting spots of suppuration in these cases, but these features are usually conspicuous by their absence.

The thermometer and the microscope also not infrequently fail. A persistence of increase of temperature calls attention to the fact that something is wrong, and its irregular or intermittent character may suggest suppuration, but some of the most striking series of wide swings have been followed by complete recovery without ever any proof of the presence of pus, and in six of our nine cases of suppuration the temperature was either falling or showing a lower range than before, when the pus was found. In two of these, successive explorations showed that while the fluid was changing from clear to purulent the temperature was falling. The number of leucocytes and the percentage of polynuclears, while often of great aid, at times fail as signs of suppuration. In at least three of our nine cases, both the leucocytes and polynuclears were lower when the pus was found than they had been earlier.

From all this the difficulty of distinguishing suppuration from persisting consolidation is certainly evident, and we are thrown upon the exploring needle as our main reliance in this uncertainty. But even here there are two discouraging considerations. The needle may fail to find the pus, and it is not without danger.

In one of our cases cloudy fluid was found three times, then there were three so-called dry taps, and then pus was found. In another case twelve dry taps were made and then pus found, all within a week. In another pus was found with the needle, the patient sent to the surgeons for operation, but

not opened because their needling was without result. The condition then progressed to a fatal ending. And again the dangers of the exploring needle, though slight, are real. I can recall four deaths due to the needle, two by hemorrhage, and two by pnemothorax. Two of these patients were nearly hopeless when explored, but the other two not very seriously ill. One of the latter, to be sure, was needled on both sides and it was double pneumothorax from puncture of the lungs which proved fatal.

In view, however, of the frequency of suppuration in the group of cases which we are considering, and of the importance of its removal if present, the exploration with the needle must be done when, after careful examination and watching, it is reasonable to suspect the presence of pus, and its probable location is evident. In this the radiogram is of great help. Sometimes the character of the shadow is of some help in case of doubt as to the character of the lesion. More often the location of the shadow or of its densest part is helpful in deciding where to puncture.

20 West Fiftieth Street.

## ACUTE APPENDICITIS IN INFANCY AND CHILDHOOD.*

By WESLEY GROVE VINCENT, M.D.,

NEW YORK.

INSTRUCTOR IN SURGERY, NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL.

This subject was chosen by the writer in response to the request for a paper of interest to the general practitioner and occasional operator rather than to the surgical specialist; for the general practitioner is usually the one who first sees such a case and upon him devolves the responsibility for early diagnosis and the institution of proper treatment. The parents, as a general rule, rely absolutely upon his judgment, seldom question his diagnosis, believe that "freezing out" is the right thing if he says so, allow him to set the time for operation if he believes one necessary, and he can often do the operation himself or have a specialist called in, as his own operative skill, cupidity, or conscience dictates. Furthermore, from the number of such cases found at autopsy, it is certain that the figures would be appalling if there were any way of determining how many cases of appendicitis in children, *who could have been saved by prompt operation,* are wrongly diagnosticated, treated, *and buried,* as cases of gastroenteritis, cholera morbus, or peritonitis of unknown origin; while doubtless in some instances a false diagnosis is made in which the physician has not taken into consideration the possibility of intra-abdominal lesions of *any* kind.

Edebohls[1] found that the literature of appendicitis, up to and including 1898, embraced over 2500 journal articles, dissertations, and books, of which more than half had appeared in the last five years of that period. Since then there have been almost innumerable further contributions to the subject, and it would hardly seem possible to add anything of value. However, in this vast amount of literature, appendicitis as found in infants and children, has received comparatively scant attention. All seem to be on the watch for and usually readily diagnosticate cases of appendicitis in adults, but apparently not in children. While many are now regularly making an early diagnosis, the rank and file of general practitioners seem to be making the same errors in diagnosis and treatment now as were made a decade ago; most surgeons are still having more late-stage cases and appendicular abscesses referred to them than early clean cases, and few apparently realize even yet that appendicitis in infants and children, as well as in adults, is not a medical but a surgical disease first, last, and all the time.

To prove the essentially surgical nature of appendicitis, Lloyd[2] followed up the histories of 25 patients who had been treated in their first attacks upon the theory that the disease belonged to the domain of medicine rather than of surgery. Of these twenty-five, six died (24 per cent.), three finally being operated upon when *in extremis* or after general peritonitis was well under way. Furthermore, eighteen cases (72 per cent.) had one or more recurrent attacks. All but ten patients finally submitted to operation, and of these ten unoperated cases three (30 per cent.), died. There were, then, but seven out of the original twenty-five who did not sooner or later come to operation or die, while the mortality in the operated cases was entirely confined to those already in desperate condition through delay.

Is it sufficiently realized that the all too frequent headline: "Died following an operation for appendicitis," in the vast majority of cases charges surgery with a death that is really due to a deferred diagnosis from ignorance, or to indecision, or to delay while experiments are being made as to the curative properties of the ice bag or coil, opium or purgatives, and fever mixtures; and that meanwhile the condition has been progressing from one requiring a simple operation, that any intelligent fourth year medical student should be able to do, to a case of gangrenous appendicitis or rupture with, perhaps, general peritonitis; and that the death should not be charged to the surgeon who stepped in at the last moment to give the patient the one desperate chance remaining, but to the doctor who has counseled or countenanced those experiments?

The writer realizes that in thus emphasizing the surgical character of the disease and the necessity of early operation almost at the beginning of the paper, he is breaking all the established rules covering the orderly presentation of a subject. Without having written a line as to etiology or diagnosis, he has already referred to treatment. This has been done deliberately and with the definite intention that if everything else in this paper be forgotten it shall at least be firmly impressed upon one's mind that *acute appendicitis calls for surgery.*

*Incidence.*—Appendicitis occurs in children under fifteen years of age much more frequently than is popularly supposed and demands consideration because of this frequency, its often insidious development, obscure symptomatology, special difficulty of diagnosis, and other peculiarities of the disease when affecting infants and children. The disease is rare under two, rather uncommon under five, but frequently seen in patients five to fifteen years of age. Male children appear to be more frequently affected than females. Morris,[3] in his first 100 operations for appendicitis, had seven cases in children ten to fifteen years old. Fowler[4] states that in the first surgical service of the German Hospital of Brooklyn during the period 1900-1912 there were 1,115 cases of appendicitis, of which 183 (16.41 per cent.) were in children under twelve years of age. Erdmann[5] operated upon 100 cases in

*Read in abstract at the October meeting of the Society of the Alumni of the Post-Graduate Hospital.

children one to fifteen years of age, between January, 1902, and May, 1907. Dowd[6] has reported three consecutive series of cases in children, 181 cases altogether; and many others have reported series numbering 100 or more. The writer has made no effort to find the age of the youngest case operated upon, but incidentally noticed that one of Cumston's[7] cases was only twelve weeks old. This child had an appendicitis with mucous membrane congested, part dark purple, ulcerated almost to perforation, and made an uneventful recovery after operation.

*Etiology.*—It was formerly thought that appendicitis could not occur in breast-fed infants when the mother's milk was normal, or in bottle-fed infants when proper care was taken in the preparation of the feedings. That this idea was entirely erroneous has been abundantly proven by actual cases. Milk-fed infants may, and occasionally do, have the disease. In 1906, Kermisson—quoted by Erdmann[8]—stated that he found reports of 25 cases under two years old, and that no meat had been given to any one of these children. Indiscretions in diet and over-feeding have been assigned as causes. Since infants, on the simplest of all diets, may have the disease, it is not surprising that older children, with their natural inordinate desire for anything and everything edible, should fall easy victims, in so far as indiscretions in diet have to do with its acquirement. Exactly as is the case in adults, there are no particular food-stuffs that can be singled out as being especially liable to cause the disease, unless possibly fruits having small pits or seeds. The reason for this exception in the young is that as the appendix in children has a relatively large mouth, is sometimes funnel-shaped, and relatively very long, foreign bodies get into and stay in the appendix much more frequently than is the case in adults. Among the many foreign bodies, other than fecoliths, which have been reported, are pins, *Ascaris lumbricoides*, pin worms, cherry stones, and currant seeds. In Erdmann's[5] series of 100 operations, he found foreign bodies in 41 cases, of which 10 were pin worms. Many observers have noted the frequency of previous gastrointestinal derangements, and it is undoubtedly true that the mucous membrane lining the appendix joins to a certain extent in the general inflammatory process during these attacks, thus laying a foundation for subsequent bacterial invasion of its walls, with resulting acute appendicitis. Of the bacteria causing acute appendicitis, we find most frequently the colon bacillus, and staphylo- and streptococci. Occasionally the gonococcus and pneumococcus have been found, while rather rarely we find the tubercle bacillus.

*Peculiarities of Acute Appendicitis in Children.*—Before taking up the diagnosis of acute appendicitis, it may be well to pause for a moment and consider some of the reasons for the difficulty of diagnosis and other peculiarities of the disease as it is found in infants and children. In the first place, there may be certain anatomic variations, such as those depending upon the degree of rotation and descent of the cecum, the great relative size and length of the appendix, and the degree of development of the great omentum, this latter corresponding roughly to the age of the child. With a high placed cecum the appendix may be found far above the usual position, running as high as the costal margin or even occupying the usual site of the hepatic flexure, as has been reported. It may be retrocecal, giving no tenderness on pressure at usual site but on pressure in the loin. It may lie behind the caput coli. It may be unusually long and large, and run to the midline above or below the umbilicus. It may dip far down into the pelvis or lie angulated or curled up at the root of the mesentery. Murphy[8] found that in children the appendix is *usually* above McBurney's point. In the adult the omentum is one of the principal agents in forming a protective wall and preventing dissemination of pus, in case of rupture of the appendix. In very young children the great omentum is still in such a rudimentary state that they are denied this protection, and we see this reflected in the greater percentage of cases of general peritonitis and the more rapid development of that complication. As a rule, the disease does not remain confined to the appendix itself as long as in adults and children are very prone to early abscess formation, while rupture of the appendix often means not one but multiple abscesses, if the patient is so fortunate as to escape general peritonitis. Strange to say, however, children seem to stand general peritoneal infections relatively better than adults; there is usually less evidence of shock, constipation is less frequent, diarrhea is rare, and they are much more likely to recover.

Another fact which adds to the difficulty of diagnosis was pointed out by McCosh[9] in 1904, and since emphasized by many authors. This is the remarkable insidiousness of onset, rapidity of spreading and overpowering intoxication in so many of the cases. Children are so subject to gastrointestinal upsets that the vomiting and early slight abdominal pain often excite little comment and no suspicion of the real nature of the trouble. Parents rather expect children to have occasional attacks of this sort, so frequently give the child a cathartic and allow twenty-four hours or more to elapse before they become sufficiently alarmed to call the physician; while by the end of another twenty-four hours the clinical picture may have entirely changed, the appendix having ruptured and this been followed by rapidly spreading general peritonitis. It is like the old cry of "Wolf! wolf!" The physician has been called so often on false alarms that his examination is apt to be superficial, his judgment clouded, and diagnosis delayed, while a particularly virulent organism has had its chance to destroy the mucosa, burst through the wall of the appendix, and invade the general peritoneal cavity. Another drawback is the difficulty or impossibility often experienced in getting an adequate history. The child may be too young to talk, unable or afraid to do so, while the parents may also be unable to furnish information that is really helpful.

Dowd[10] has summarized the peculiarities of appendicitis in children as follows: "We may say that (1) the rapidity and insidiousness of the disease are much greater; (2) that the percentages of diffuse and general peritonitis is greater, probably because the omentum is less apt to enclose the inflamed appendix; (3) that the pain is almost always present, but is more difficult to interpret; (4) that the vomiting is almost always present and is frequently many times repeated; (5) that the abdominal palpation in the majority of cases is as satisfactory or more satisfactory than in adults, but in a few cases is absolutely misleading; (6) that constipation is much less likely to be present; (7) that they have a greater ability to deal with general peritonitis than adults do; (8) that during the acute progress of the disease delay is more dan-

gerous than in adults, because of the insidious course of the disease and the greater tendency to peritonitis, and immediate operation is to be advised."

*Symptoms and Diagnosis.*—As has already been suggested, the diagnosis is sometimes particularly difficult. In typical cases in the older children the symptoms follow the same order, palpation gives the same information, and diagnosis is as easy as in adults. It is the cases occurring in the younger children (under five) and the atypical cases that especially try one's diagnostic ability. In general, the younger the patient the more atypical the case is apt to be. Whenever possible, a good history should of course be obtained, not forgetting to elicit information regarding any previous attacks of similar nature, or special susceptibility to gastro-intestinal disturbances.

From the experience gained in 2000 operations for appendicitis at all ages, Murphy[8] found that usually the symptoms came in a definite order and followed one another at approximately regular intervals. These symptoms were "(1) pain in the abdomen, sudden and severe; (2) nausea and vomiting within a few hours, most commonly three of four hours, after the onset of pain; (3) general abdominal sensitiveness, most marked on the right side or, more particularly, over the appendix; (4) rise of temperature two to twenty-four hours after onset of pain." He further says: "The symptoms occur almost without exception in the above order," and "when that order varies I always question the diagnosis."

*Pain* was a constant and uniform symptom, usually colicky, varying in severity, and becoming most intense about four hours after its onset. It usually subsided gradually. Abrupt decline within first thirty-six hours was due to evacuation of infective material into cecum, rupture, or complete gangrene of the appendix. Dowd found pain a practically constant symptom. The secondary pain after thirty-six hours is usually not colicky, and is due to peri-appendical irritation or inflammation. Sudden severe pain after initial subsidence generally, if not always, means a beginning local or general peritonitis from perforation. Because of anatomic peculiarities in children the pain may become localized at other points than the usual situation, particularly high up toward the liver, near the umbilicus, or low down, and giving reflex disturbances of the rectum or bladder, strongly emphasized by some as very significant symptoms when they occur. It is, however, often difficult or impossible to get an accurate localization of the pain, hence this symptom is often difficult to interpret and may be of little value except when taken in conjunction with other factors, particularly abdominal sensitiveness.

*The primary nausea and vomiting* are reflex symptoms due to irritation and over-distention of the appendix. The secondary vomiting and the persistent vomiting are due to involvement *outside* of the appendix, that is, infection of the peritoneum. Nausea and vomiting are practically constant symptoms, and McCosh and others have emphasized persistent vomiting as a symptom of great diagnostic importance. Campbell[11] hits the nail on the head when he says: "When called to treat a case with bellyache, vomiting, and fever, proceed at once to prove that it is not appendicitis before attempting to prescribe."

*General abdominal sensitiveness* is a symptom of great significance, and, taken in conjunction with early sharp colicky pain, nausea, or vomiting, should immediately lead one to investigate the appendix. Fever may or may not be present when the sensitiveness first appears. It is at first diffuse and the abdominal wall is not particularly rigid. As the inflammation and distention of the appendix advance general rigidity, particularly of the right abdominal muscles, soon develops, to be followed later, as the acute tension subsides, by a relaxation of those muscles not directly concerned in the protection of the inflamed area. In this way we get local tenderness and rigidity, or muscle spasm over the site of the appendix, whatever its location. Murphy believes that in the early stage, while the inflammation is confined within the appendix, the "tumor" felt is usually contracted muscle fibres directly over the situation of the appendix, which may itself be even retrocecal. If the tenderness has once been limited to a small area and increases suddenly, together with an exacerbation of pain and nausea, or vomiting, we should expect to find a breaking down of the primary protective adhesions and involvement of further areas or a general peritoneal invasion. In palpating after the first twenty-four hours, caution as to the amount of pressure used is extremely important since the thin wall of protective adhesions is so easily broken down, particularly in very young children where the omentum does not form part of the limiting wall. In acute cases don't try to find out how many concretions the appendix contains until *after* it is in the pan. This remark may sound flippant and unnecessary, but it is a very important point, since the writer's observation of staff men and others has shown that it needs to be strongly emphasized. Gentleness in manipulation is particularly necessary after the patient is anesthetized and the natural reflex muscular protection has been eliminated. If, in a case of evident severe infection and after the general tenderness has become localized, we have a *sudden* cessation of pain and a relaxation of the overlying muscles, particularly if within the first forty-eight hours of the disease, it is almost certain that the appendix has become gangrenous; while the combination of this feature with a sudden drop in temperature while the pulse remains high almost invariably means gangrene and perforation, with beginning involvement of the general peritoneal cavity. The size of the mass felt often bears little relation to the amount of pus contained within the protective wall. Fluctuation is rarely obtained, and then only when there is a large abscess with thin anterior wall. While it is sometimes impossible to get definite localization of pain in very young children, muscular rigidity is usually easily determined. Dowd found it practically constant and considers that abdominal palpation in these cases has been rather more satisfactory than in adults. After the local tenderness is established Erdmann[12] has found that "almost invariably the little patients unconsciously place their hands in the region of the appendix to ward off manipulation in this region," and further experience led him to emphasize this point in a later article.[5] The abdominal muscles of children are evidently particularly sensitive to inflammations beneath them, and local muscular rigidity is thus the best possible evidence of an underlying inflammatory process of some kind. The writer has already referred to the abnormal positions in which the appendix may be found, hence will merely mention here that spasm may be found in lumbar or ilio-psoas groups of muscles. Rarely acute appendi-

citis and acute suppurative processes in the right hip joint have been confounded for this reason. With otherwise classical signs but no local rigidity to be found, the appendix may lie deep in the pelvis and rigidity remain general or disappear, and a rectal examination may disclose the condition. These cases are also apt to have painful or very frequent micturition, as previously pointed out. With the appendix in other situations rectal examination may or may not be of value, but should always be employed when children present any obscure abdominal condition. Campbell believes that in the majority of cases the diagnosis can be made by the abdominal examination, irrespective of the history. While palpating, the child's face should be watched, as his expression often indicates when the tender spot is reached. Mass may or may not be present, depending upon (1) the period of the disease or (2) the virulence of the attack. In average cases it may be felt in the second twenty-four hours; in mild or very virulent cases there may be no mass. Respiration in young children is normally of the abdominal type. With costal type and abdomen held rigid, a painful abdominal or pulmonary lesion should be suspected, since general rigidity may also be present in pneumonia, diaphragmatic pleurisy, or subphrenic abscess.

*The temperature* never fails to rise at some time during the early stage of the disease. In acute severe infections it is present within a few hours; in mild cases, somewhat later. It may subside gradually within twenty-four hours, due to the expulsion into the cecum of the exciting material. If sudden drop occurs, suspect gangrene or perforation. Remission with subsequent gradual increase means invasion of new adjacent structures, while sudden increase may mean multiple abscesses or general peritonitis. These secondary elevations of temperature *always* mean further involvement of tissue, are danger signals that even the most rabid adherent to the old-fashioned medical tenets cannot afford to disregard, and indicate that immediate operation is imperatively demanded.

*The blood count*, simple or differential, has not appeared to the writer to be of much value except as it is concerned in differential diagnosis. In all acute inflammatory conditions in previously healthy children the leucocytosis is usually very marked. A leucocytosis is merely an indication of the fight which the body has been making, may be misleading, and gives absolutely no information as to the condition of the local focus of infection at the time the blood is taken for examination. This is particularly true in fulminating types of acute appendicitis, and the writer desires to sound a note of warning against placing any dependence in the findings or wasting any time in waiting for a report in the presence of other indubitable evidences of this disease. On a number of occasions the writer has operated within one hour after blood examination has shown very high leucocytosis with high percentage of polynuclears; but as there had also been a sudden drop in temperature, cessation of pain, and local tenderness, while the pulse remained rapid, immediate operation was indicated. Operation repeatedly showed a gangrenous appendix with few or absolutely no protective adhesions surrounding it.

*The pulse* usually follows the temperature, and with it is usually an indication of the degree of toxemia. The significance of high pulse with suddenly dropping temperature has already been pointed out.

Collapse appears rapidly or slowly after perforation, depending upon the type and virulence of the infection. Murphy found the streptococcus infection most rapid; staphylococcus, slowest; colon bacillus, intermediate; though sometimes acting with overwhelming virulence.

*Differential Diagnosis.*—In the course of this paper the writer has repeatedly emphasized the fact of the occasional difficulty one experiences in diagnosticating acute appendicitis in infants and children. The conditions which we are called upon to differentiate most frequently are (1) gastroenteritis; (2) pneumonia; (3) diaphragmatic pleurisy, and (4) intussusception. Among others occasionally to be differentiated are (5) subphrenic abscess; (6) glandular tuberculosis (in the mesentery), and localized tuberculous peritonitis; (7) general peritonitis of unknown origin; (8) fecal impaction; (9) typhoid fever; (10) strangulated hernia; (11) pyelitis affecting the right kidney; (12) stone in right kidney or ureter; (13) pyosalpinx, inflamed ovary or ovarian dermoid; (14) inflamed undescended right testicle; (15) duodenal ulcer; (16) intra-abdominal tumors; (17) acute infections of right hip joint; (18) malaria, as emphasized by Brickner[13]. While this list may seem long, it does not by any means include all the conditions which have simulated or delayed the diagnosis of acute appendicitis. Illustrative cases covering acute appendicitis in its relation to each of the above-named conditions have been reported in varying numbers and may be found in the literature. We must also remember that acute appendicitis sometimes occurs coincident with or during the course of pneumonia, typhoid, tonsillitis, measles, or other febrile disease.

*Points in Differentiation.*—(1) From gastroenteritis: The symptoms sometimes correspond so closely with those of appendicitis with mild onset that positive diagnosis may be impossible during the first twenty-four hours. However, in gastroenteritis the initial fever is usually higher, while pain is rarely so severe and usually does not become localized, or, if so, it is apt to be near the navel or in the epigastrium. Diarrhea is the rule, while the opposite condition usually obtains in appendicitis. The differential leucocyte count may be of value. McCosh[9] believed that "persistence of vomiting, with severe pain for more than twenty-four hours, especially if there be no diarrhea, favors the diagnosis of appendicitis." Obstinate constipation with any one other symptom of the disease he believed sufficient to warrant operation. General abdominal sensitiveness, with localized muscle spasm is, however, the surest indication that the appendix is the seat of the trouble.

(2) From pneumonia: One of the most fruitful sources of error, and one which is sometimes very hard to differentiate, is beginning pneumonia in the right lung, particularly if it be of the central type. In its incipiency, pneumonia is occasionally accompanied by right-sided abdominal pain and muscular rigidity, and under these circumstances even the most careful and experienced diagnosticians, both pediatrists and surgeons, have been misled. Sometimes the mistake has been in one direction, sometimes in the other. It occasionally happens that two such experts are absolutely unable to make a positive diagnosis until, after several days elapse, either the usual typical local evidences in the chest or development of abdominal mass make the condition clear. Rectal examination occasionally has served

to show the appendix at fault, and thus clear up the diagnosis in some of these obscure cases. No definite rules can be formulated for early differentiation of these atypical cases of pneumonia with confusing abdominal symptoms. Delay in the diagnosis is not only excusable, but unavoidable, unless one may have the benefit of the information to be gained by the *x*-ray in the hands of an expert radiographer. Pisek,[14] in conjunction with radiographers at the New York Post-Graduate Medical School and Hospital, and elsewhere, has done considerable work along the line of early diagnosis of pulmonary lesions and in the study of conditions affecting the gastrointestinal tract in infants and children. He has achieved some very brilliant results in obscure pulmonary cases, and from his experience is convinced that where the diagnosis rests between central pneumonia and appendicitis it can be quickly cleared up by this method when expert radiography is available. Such atypical cases as these are rather unusual, but they occur often enough to instil a wholesome fear of sometimes overlooking the condition and not discovering the error until we have cut down upon a normal appendix. In the ordinary case there should be no difficulty in ruling out pulmonic involvement. Blood examination gives no aid here, but with pneumonia we often have an initial chill, occasionally a convulsion; there is usually more rapid elevation of temperature, much more rapid breathing, evident prostration, different facies, occasional cyanosis, cough, and the physical signs in the chest. There may be vomiting and diarrhea, but usually no abdominal pain or rigidity. These points are sufficient for differentiation in the great majority of cases of bronchopneumonia, while with lobar pneumonia, in addition to the above symptoms, there is often typical pleuritic pain and friction sounds, while the initial rise of temperature is still more marked and more likely to be ushered in by a definite chill.

(3) From diaphragmatic pleurisy: In this affection also we may have abdominal pain and muscular rigidity, so here again is a problem which may defy solution until positive localizing signs have become manifest. Blood tests are of little or no value. There is nothing characteristic about the pulse or temperature, but the breathing is apt to be much more rapid with pleurisy. Vomiting is a symptom common to both. In pleurisy there may be a certain fixation of the lower ribs, but abnormal chest sounds may be absent. From the inter-relation of pleural and lumbar nerves we may have as severe abdominal pain and as rigid muscles in one as in the other. In the absence of definite localizing symptoms, and with negative results from rectal examination, the writer knows no method of early differentiation unless radiography after a bismuth meal may furnish the clue. Summers,[15] however, believes diaphragmatic pleurisy can be very readily recognized. He states that he "found almost complete absence of the respiratory murmur over the lower part of the right lung." The writer has never been able to verify this observation.

(4) From intussusception: Ordinarily there should be but little difficulty in differentiating these two conditions. The persistent vomiting, rhythmic pains, bloody and mucous stools, and greater degree of shock all point to intussusception. The mass may or may not be felt on abdominal palpation, but, if felt, is usually above and to the left of the appendix region near, or even beyond, the median line. Rectal examination often discloses the intussusceptum protruding into the rectum. When the tumor is in the ileocecal region, it may occasionally be mistaken for an inflammatory mass. Sometimes the appendix forms part of the intussusceptum, but hardly influences the clinical picture characteristic of intussusception. Rarely the diagnosis may be doubtful, but as both conditions demand early operation no harm is done unless precious time is wasted by some procrastinator or by one who still believes in medical treatment of one or the other of these conditions. Snow and Clinton[16] have shown that the *x*-ray is sometimes of value in these cases also, their *x*-ray photographs illustrating the condition found in two cases of intussusception being very interesting and instructive.

It hardly seems necessary to differentiate *seriatim* the other occasional to very rare causes of uncertainty in diagnosis. The history, physical examination, with the routine employment of abdominal, rectal, and bimanual rectoabdominal palpation and the judicious use of one or more of the many modern diagnostic aids, should differentiate acute appendicitis from any of the above mentioned sources of error without much difficulty. The simple blood count, differential leucocyte determination, examination for plasmodium malariae, and blood reactions (Widal, Wassermann, etc.); the urine examination (with cystoscopy, ureteral catheterization, and functional tests for individual kidney sufficiency, possible in the older children); the von Pirquet; the numerous other tests, including possibly Abderhalden's recently advanced serum test for malignant tumors (since Erpicum's[17] correct results in forty-two cases are certainly impressive); and, finally, the *x*-ray, since giant strides have been made in recent years in *x*-ray diagnosis of pulmonary, gastrointestinal, and other intra-abdominal conditions by Cole[18], Pisek and LeWald,[19] Chapin,[20] Morse,[21] Quimby[22], and a host of others, following improvements in apparatus and refinements of technique which have allowed instantaneous exposures, singly or in rapid sequence, and the development of greater skill in the interpretation of these plates; any or all of these resources may be called to our aid in the larger centres, and most of them even in the country village. With these and such a multiplicity of other diagnostic aids at our command, is it too much to ask that an early diagnosis be made in these cases of acute appendicitis, whatever the age of the patient?

*Treatment.*—The writer believes that with extremely rare exceptions we should no longer consider that there is a medical treatment of acute appendicitis. The treatment is, as suggested by Campbell, preoperative and operative. The preoperative treatment consists in rest and fluid, or no diet except water (and the ice bag as a placebo, if you insist) while waiting to confirm the diagnosis. No active catharsis while any doubt exists as to the possibility of acute appendicitis. After the diagnosis of acute appendicitis is made, possibly the ice bag or coil and opium in some form while preparing for the operation, which should be done as soon as possible. Before operation the lower bowel may be emptied by enema or left alone. Children bear short operations well, but not extensive bowel manipulation or loss of much blood. With the tenderness in the typical situation, the writer believes in using the McBurney incision if there is no mass, or if the mass is well confined to that region. Right rectus incision for all other cases

where the mass or tenderness is high, nearer the median line, or very low. When the rectus incision is used, it should be made well to the outer edge of the muscle. The operation in children before complications develop is usually as easy or easier than in the adult. Early clean cases are of course not drained. When the appendix has been found gangrenous, or a little fluid and flakes of lymph are present, a small cigarette drain may or may not be used, depending upon the condition of the periappendicular tissues, and as judgment dictates in the individual case. Abscesses are sponged out and freely drained. No peroxide or general irrigating. Wound closed by layers, to emergence of the drain or drains, except occasionally in especially virulent cases or where drains run to several abscess cavities and the incision is short. In some cases one or more provisional sutures may be placed at point of emergence of drain, to be tied after its removal if the condition warrants this procedure within twenty-four to forty-eight hours.

Nothing will be said regarding technique of operation in late stage cases, since the surgical portion of this paper is directed not to the surgical specialist, but to the occasional operator, who seldom is justified in attempting the surgery of these often very complicated cases. The proper handling of such cases often requires the exercise of rare judgment and taxes the resources of even the most skilled and experienced surgeon. Any reader of this paper who operates seldom or only in emergencies, or through force of circumstances (at a considerable distance from a competent surgeon), and who might thus be compelled to operate upon late stage cases of appendicitis in children, is referred to the excellent articles by Torek,[23] Hawkes,[24] Hotchkiss,[25] Murphy,[8] and others on the treatment of diffuse suppurative peritonitis and other conditions complicating or following appendicitis.

*Results of Surgical Treatment.*—Erdmann, in 100 cases operated upon at all stages, had 7 deaths: pneumonia, 2; general peritonitis, 4; subphrenic abscess, etc., 1. Twenty-four cases had perforated; 50 were gangrenous. There were 5 interval cases. Thirty-seven cases had to be drained. Fowler, in his last 100 cases, had 3 deaths: 2 from septic peritonitis, 1 from general septicemia in a case operated on in less than twenty-four hours, where there was a very acutely inflamed appendix with a perforation, and with an escaped enterolith lying directly on the iliac vein. Dowd, in 41 cases operated upon within forty-eight hours had one death, while in the entire series of 181 cases there were 11 deaths: 7 in the first series of 70; 4 in the second series of 50, and none in the third series of 61 cases.

The percentage of mortality in operations for acute appendicitis undertaken in the early stages of the inflammation is shown by hospital statistics to be very low. It is practically nil. In the cases operated upon after plastic lymph has been thrown out, adhesions have begun to form, seropurulent exudate is present, and the mesoappendix and head of the cecum have become infiltrated and friable, the mortality gradually increases; and in the cases where gangrene has supervened or the appendix has ruptured, and so on up to the cases with general peritonitis, the death rate increases by leaps and bounds. Is it not perfectly clear that this increase is the mortality of delay and not of surgery? And in these desperate cases, if, by dint of good fortune, a rugged constitution, skilled surgery, careful nursing, and after weeks of drainage with the attendant torture of frequent dressings, the patient escapes death, he often recovers with a fecal fistula or a weak point in his abdominal wall positively inviting a hernia, or with a mass of adhesions that may later cause intestinal obstruction or result in perverted bowel function, easily giving rise to intestinal toxemia and chronic invalidism. How frequently we see patients undergoing the discomfort and danger of a second operation to relieve conditions the direct result of delay in the operative treatment of an antecedent acute appendicitis, when immediate operation probably would have allowed them to leave the hospital after a smooth and easy convalescence, with a solid abdominal wall and with no network of adhesions within the abdomen to lay the foundation for future complications!

If the reader has been one of the procrastinators, and if consideration of the facts presented in this paper results in more keen and careful examination, earlier diagnosis, and prompt operation in future cases of acute appendicitis, whatever the patient's age, it will not have been written in vain. It is true that the mortality is somewhat higher in such operations on children than on adults, but it is still very low, and one must remember that the mortality in medically treated cases that are allowed to go on to gangrene and rupture with general peritonitis is practically 100 per cent., while late surgery in such cases saves comparatively few; and let us also remember that an innocent appearing start is no guarantee that we shall not have a desperate case on our hands before the expiration of forty-eight hours. Early diagnosis and operation within the first forty-eight hours means approximately 100 per cent. cures. Delay invites disaster, with the useless sacrifice of many lives.

Acute appendicitis calls for immediate surgery.

# GENITAL FISTULÆ IN THE FEMALE.

By CHARLES J. DRUECK, M.D.,

CHICAGO, ILL.

Genital fistula is perhaps one of the worst complications we are called to attend in pelvic troubles because their effect upon the patient's nervous temperament and general health is far out of proportion to the pathological lesion, and no matter what the cause may be the sufferer ostracizes herself from even her friends.

Fistulæ in the upper part of the vagina result most frequently from malignant disease, while those in the lower part of the vagina result from trauma, protracted and difficult labors, imperfect union following operations, and ulcerative processes of syphilis, tuberculosis, or foreign bodies. Anatomical malformations sometimes contribute, although to a small degree.

Although there are a number of different varieties of fistulæ they may be classified for brevity into those from the vagina to either the urinary or fecal tracts.

*Symptoms.*—The actual solution of the tissues that is to constitute the vesicovaginal fistula is preceded by the development of bladder symptoms. In postparturient cases these symptoms may occupy but a few days, but when ulcerative processes are the cause the bladder symptoms may occupy weeks or months. They begin with frequent micturition and dysuria, showing irritation of the bladder. Later hematuria informs us that the epithelium of the bladder is giving way, and then suddenly the urine gushes from the vagina. From this time on incontinence of urine is more or less complete and the vagina, external genitals, and thighs are excoriated from the constant dribbling of urine, and the patient is embarrassed by the urinous odor about her at all times. If the fistulous opening is small and high in the vagina, incontinence will occur only when the bladder is filled or when the patient is recumbent and not when she is up and about. The urinary salts are deposited about the fistulous opening and in the vagina, and when removed, either purposely or by the gradual breaking down of the crusts, the surfaces are found ulcerated and bleeding. Contraction is going on in one ulcer while crusts are forming in another place and the opening into the bladder soon becomes circuitous. In rectovaginal fistula there is but partial fecal incontinence unless the sinus is very large (in the late stages of cancer). In the traumatic forms the opening is very small. Frequently it is only pin hole in size and only liquid feces escape. But no matter how small the opening is the intestinal gases are uncontrollable and escape with a whistling noise.

*Diagnosis.*—Urinary or fecal incontinence occurs in so few other conditions that fistula must be always considered when this symptom is complained of. In puerperal patients sloughing progresses gradually for several days or a week and then the patient has the urine suddenly gush out of the vagina. If the opening is large it may be detected by the palpating finger or with a sound; but if small it must be located by inspection, that is, by seeing the discharge come through the mucous membrane. For examination, place the patient in the lithotomy or Sims' position in a good light. Forcibly retract the vaginal wall opposite the expected fistular site and then carefully examine all of the exposed mucous membrane. Even with careful work it may be necessary to distend the bowel or bladder with permanganate or some analine solution and watch for its oozing through the wall into the vagina. Sometimes instead of finding a definite opening from the bladder, the vesical mucosa will extrude into the vagina and the urine seep through the thin wall.

*Prognosis.*—There is a vast difference in the history of fistulæ produced by incision or laceration, and fistulæ resulting from sloughing produced by bruising. The former leaves a clean cut healthy edge which tends to granulate and contract until the opening is closed. Palliative treatment such as rest, cleanliness, and relief of excoriations of the outer parts is all that is needed. If the granulations seem sluggish and the fistula is very small, the edges may be freshened, and the bladder drained with a retained catheter through the natural passages for a week or ten days. Traumatic fistulæ should not be treated surgically for at least two months, because the majority of them close spontaneously under palliative treatment. Keeping the urine acid and frequent irrigations of the vagina and bladder assist healing. When the mucosa has broken down by necrosis and sloughed away, the history of the fistula is different. The wound edges are poorly nourished and uneven. Granulation goes on at one place while ulceration is still unfinished in another. About this sloughing mass is a region densely filled with leucocytes which block the circulation. The lymphatics are also filled with débris which they are trying to dispose of. It is little wonder with such pathology that regeneration does not progress or that urinary salts incrust the surfaces. These fistulæ (those due to ulceration) do not heal of their own accord.

*Treatment.*—Tentative treatment and the application of caustics are almost useless. In patients presenting recent lesions cleanliness and keeping down fatty granulations will assist nature to close the opening but where the fistula has existed for sometime and is surrounded with cicatricial tissue nothing but operative procedure offers any hope of cure.

Rectovaginal fistulæ that open within one inch from the anus are best treated by splitting the tissue between the fistulæ and the skin, thus converting the wound into a small complete laceration of the perineum and then repaired as such. Fistulæ high up in the vagina and those entering the bladder require plastic operations of various forms. The style of operation to be used depends upon the location of the fistula, its connections and form, and conditions peculiar to each case at hand. The greatest handicaps to plastic work here are tension on the sutures, and wound infection. The danger of both of these complications is lessened by placing the line of suture in the line of axis of the vagina. This utilizes any laxity of the vaginal wall. With old persistent fistulæ plastic surgery calls for considerable ingenuity in the operator. The operation to be described hereafter is given only as a pattern which the reader must modify and twist to best suit his individual case. If fistulæ into the rectum and bladder coexist the rectovaginal opening must be first repaired and allowed to heal before attempting the vesical sinus, as otherwise the bladder stitches would surely be infected.

*Preparatory Treatment.*—All inflammation and induration must be relieved. Lime salt deposits are to be removed and the tissues brought to nearly normal before any operative work is begun. The urine should be rendered bland by administration of benzoate of soda or potash. To remove the crusts

of lint that surround the fistulous edges copious douches of boric acid solution frequently repeated will give good results, or nitric acid, 1 to 4,000, may be used. Ulcerations and abrasions should be brushed with nitrate of silver solution, 5 grains to the ounce, every few days. If any scars or bands distort or stretch the vagina, they must be divided and allowed to heal on the stretch. The details of the treatment of scars and bands cannot be taken up in this paper. The urethra sometimes contracts from disuse or cicatrices and must be dilated before repairing the fistula. Where the fistula is dependent upon some other diseased condition, as cystitis or tuberculous ulcers of the bladder or rectum, these conditions must be corrected before any plastic operation will be successful.

*Operation.*—In general the plan of this operation is to make a trapdoor from the vaginal mucous membrane on one side of the fistula and turn it into the bladder or rectum as the case may be. The free edge is then stitched to the opposite side of the fistula. This flap is then reinforced by imbricating a portion of the opposite wall over it. This second flap is fastened near the base of the first. The flaps may be taken from either side of the opening. A lateral flap is preferred rather than one above or below the opening.

The vagina is widely dilated by means of Sims' specula and the fistula is steadied with tenacula. A flap one-quarter of an inch larger than the opening is then marked off on one side with a knife or sharp scissors curved on the flat. The vesicovaginal septum is split and the vaginal mucosa lifted but leaving the vesical wall and areolar tissue intact. This dissection is carried to within one-eighth of an inch of the fistulous edge, and the remaining tissue is used as a hinge to lay the flap over the opening like a patch. The size and shape of the flap must be determined in each case and varies from the crescent for a round fistula, to a triangle or oblong in irregular openings. Whatever the shape of the opening the flap must be large enough to cover it completely and have about one-eighth of an inch lap all around.

The next step is to split the vesicovaginal septum around the edge of the fistula opposite the side of the flap, thus making another flap beginning at the edge of the fistula and hinging about three-eighths to one-half inch back of the opening. To fasten the flaps in place, a curved needle carrying fine catgut is inserted into the flap about one-quarter of an inch from the edge, passed through the connective tissue deeply down to but not through the mucosa and curved back and out again on the same surface about one-eighth of an inch from the edge. Passing over to the vesical half of the flap of the opposite side, the needle is entered in the fresh cut surface, passed down to but not into the vesical mucous membrane, then turned and brought out again on the cut surface back in the angle of the wound. This is a Lembert stitch. It provides a broad surface for approximation and also lifts the wound edge above the level of the bladder wall.

The fistulous opening is now closed, but the flap of vaginal mucosa remains to be fastened. A curved round needle threaded with fine catgut is now passed through the free edge of this flap, carried over the wound, and into the fresh surface on the opposite side, where it is passed into but not through the vaginal wall and brought out again on the vaginal surface. This stitch very closely resembles that used in suturing for repair of any vaginal tear. The stitches are placed about one-quarter of an inch apart. This second flap closes the vaginal wound and reinforces the flap which closes the fistula. By this method a double-breasted coat effect is obtained. The two rows of stitches are each in the line of axis of the vagina, but are not superimposed on each other. This provides a wide surface for union and raises the vesical line of suture above the level of the bladder wall and thus lessens the danger of infection. After the sutures are inserted but before they are tied the bladder should be thoroughly washed out to remove all clots.

*After Treatment.*—At the close of the operation a catheter should be inserted into the bladder and retained for two or three days, and after that the bladder should be catheterized every three hours for the balance of the first week. Let me say just a word here about the care of the catheter while it is retained within the bladder. It must be examined every few hours to see that it does not become occluded, and the bladder dangerously overdistended. It should also be removed once or twice in each twenty-four hours, washed, and replaced under the strictest asepsis. Removing the catheter each day greatly relieves the patient and it may be well to leave it out for one-half hour or so each time it is cleansed. A good dose of castor oil or a saline should be given on the morning of the second day and after that the bowels should be kept free and the movements soft. No vaginal dressing or douches are given unless for special indications. The patient should be kept in bed for ten days, and it is preferable that she should lie on her side instead of on her back. By so doing the urine gravitates away from the sutures when the bladder is only partly filled instead of constantly bathing the wound. After the patient leaves her bed she should be kept under restraint for at least two weeks, and not allowed to be upon her feet any great time until the tissues may have obtained more strength.

Recently quite a number of plastic operations have been suggested for the relief of this very troublesome condition. Each operator suggests a different method but all aim to use the tissue obtained by freshening the edge of the fistula instead of discarding it as is done in the older classic method. This multiplicity of operations suggests failures in all of them and it is well to remember that much depends upon the case in hand and upon the inventive ability of the operator.

## USES AND ABUSES OF SALVARSAN AND MERCURY IN SYPHILIS.

By ELLIOTT C. BURROWS, M.D.

NEW YORK.

In every phase of the treatment of syphilis there is great need of intelligence and caution, for the drugs used are beneficial and curative only in so far as their harmful effects are avoided. In a series of 10,000 personally observed syphilitic patients treated with salvarsan and mercury a truly marvelous abortment of the disease in early cases and a shortened period in obtaining cures in the secondary and tertiary stages have been repeatedly observed with these combined remedies, properly used. The abuse of salvarsan by the unskilled and unscrupulous has done great harm as is shown not only by the neurorecurrences but by approximately 400 useless fatalities reported in the three years of its use as compared with only 70 deaths on record from mercury

in the last sixty years. However with a proper knowledge of its uses and contraindications, I have found salvarsan most efficient and safe in a very large series of cases.

Neurorecurrences are common after the indiscriminate salvarsan injections in the second and third stages of syphilis when the organism is flooded with spirochetes. It is plausible to assume that the spirochetes are leading a saprophytic existence on the meninges, doing no harm until the toxic action of the salvarsan is felt by the tissues under them, especially the capillaries. This reduces their resistance and the spirochetes can then exert their destructive action. Salvarsan is not only improperly used by the ignorant and unscrupulous but its use is abused by the quack, who to obtain an exorbitant fee for this comparatively inexpensive remedy, assures the patient that one injection will cure. All of these patients return in a year or later with symptoms of uncured syphilis. Another type of quack is the pseudospecialist who receives in advance a fee for at least three injections, whether or not they are indicated. The danger from these repeated injections is great; practically all cases of neurorecurrences coming under my observation give a history of such injections during the second and third stages of the disease. As many as ten weekly injections are sometimes given, each followed by a Wassermann test with the object evidently of obtaining a negative Wassermann regardless of the danger to the patient and a possible fatal termination. Such haphazard treatment is of unavail and in cases at all late gives universally 3 to 4 plus Wassermann's. Most accidents occur in such cases and this unscientific therapy should be discountenanced. The best symptomatic results and the quickest permanent negative Wassermann tests are obtained on the other hand in the second and third stages by weekly injections of mercury and infrequent safe doses of salvarsan. However, a persistent positive Wassermann reaction following a thorough and systematic course of salvarsan and mercury, may frequently be changed to a permanent negative Wassermann reaction by the temporary discontinuance of these drugs, substituting in their place sodium cacodylate which should be injected intramuscularily twice weekly for two months.

In the first stages of syphilitic infection the spirochetes are most active and most susceptible to drugs and the disease is curable in direct proportion to the timeliness with which salvarsan injections are given. Early chancres can be diagnosed by the microscopic dark field examination for the spirochetes and should be followed at once by excision of the lesion, or when this is not practicable the injection of the lesion with a 1 per cent. solution of mercuric chloride, the application of the thermocautery, dusting the lesion with calomel, and by the immediate intravenous injection of salvarsan, repeated in four days, and followed by a six weeks' course of mercury, terminated with a third intravenous salvarsan injection. This is the only efficient abortive treatment. In the second and third stages of syphilis it is essential to arouse the avidity, and to stimulate the appetite of the spirochetes for drugs with small doses of mercury, sweating procedures, iodides or thiosinamine, thus activating the virus before commencing salvarsan therapy. In the secondary stage salvarsan should be used with great caution at infrequent intervals, its use being combined with intramuscular injections of mercury, salvarsan being used principally to control the symptoms. In the tertiary stage with late manifestations of syphilis with marked involvement of the nervous system, such as severe and continuous headache, insomnia, irritability, backache, inability to work, asthenia, and vertigo, the treatment should begin with a course of mercury followed by the cautious intravenous or at times intramuscular injections of salvarsan in small doses. Syphilis in all three stages may be controlled during the treatment by the Wassermann test which should never be performed until at least ten days to two weeks have elapsed after the last medication.

The intravenous use of salvarsan, properly administered, is devoid of danger provided it is given in suitable dosage and at infrequent intervals, apart from cases of early infections. Salvarsan should never be used in patients exhibiting cachexia or severe visceral involvement, or in the presence of extensive cerebrospinal involvement or in those suffering with other infections such as grippe, etc. On account of the possible idiosyncrasy of some patients to arsenical intoxication patients should be within reach of the physician after each treatment with salvarsan. That many cases are promptly and radically cured by its use with mercury is shown by the large number of reinfections which are now being recorded, this reinfection implying that the original disease has been cured. Before the advent of salvarsan reinfections after mercurial cures of syphilis were extremely rare.

Precautions as to the water used for the solution of salvarsan, freshly distilled water being preferable, the promptness of the intravenous injections following the preparation of the solution, and the usual aseptic surgical technique are details of importance. The patient's health during treatment is important; he should feel better than he has felt before beginning the treatment, he should have a good appetite and should feel fit for work. The toxic effect of either drug by lowering the resistance lessens the chance of either a symptomatic or a radical cure. The insoluble salt of mercury injected deep into the gluteal muscles once a week is the most efficient form of mercurial treatment. Mercurial rubbings are filthy and inaccurate. The internal use by pill, tablet, or liquid is slow of action and unscientific, and it is impossible to give a sufficient amount of mercury by the mouth to procure satisfactory results without causing gastrointestinal disturbances which are much to be avoided in the treatment of syphilis. The writer prepares his own mercurial injections using the salicylate preferably, the patients receiving on an average of 1½ grains weekly. The injections are given under aseptic precautions; they are scientific and accurate in that a definite quantity is absorbed at each injection. Syphilitic symptoms disappear with such rapidity that the mercurial injections may be favorably classed with salvarsan in this respect. The injections do not produce abcesses or indurations and are painless. Potassium iodide is a most useful adjuvant in selected cases and should be used in large doses starting with 100 grains a day up to 1 ounce, keeping this up for several weeks. Large doses are far better tolerated than the daily doses of 10 or 15 grains. The drug should be given one-half to one hour after meals when digestion is well advanced, and is advantageously given in vichy, hot or cold water, or milk.

Inadequate treatment does actual harm, merely rousing the spirochetes without exterminating them; also, mild, early syphilis should not be treated

with correspondingly mild measures, as general paresis most frequently follows such cases. It is yet too early to state the time required for treatment in individual cases, but the basis upon which this is decided has for its object the positive elimination of all possible destructive and unfortunate complications of late uncured syphilis. However, from personal observations it can be stated that patients with a negative Wassermann reaction two years after the discontinuance of treatment, are cured. An indicative test should be insisted upon at the end of three to six months and one year, so that no time is lost should evidence of a return be present. Here is the most difficult responsibility for the conscientious physician in the treatment of syphilis and one eagerly avoided by the unscrupulous. It is only by having the full confidence of our patients whereby thorough treatment and necessary after-observation are possible, that both the physician and the sufferer can finally feel confident that a cure has been effected.

40 East Sixty-second Street

## EFFECT OF TYPHOID VACCINE ON SUGAR OUTPUT IN DIABETES.

By FRANCIS A. PRENDERGAST, M.D.,

BROOKLYN, N. Y.

Having seen the statement made that in patients suffering from diabetes the sugar disappears from their urine during an attack of typhoid fever and well on into convalescence, we thought it would be of interest to know what effect typhoid vaccine would have on the sugar output in diabetic patients.

The experiment was tried with four patients in the wards of the Kings County Hospital. Patients were first put on the regular hospital diabetic diet and an attempt was made to get their average twenty-four hour amount of sugar—then with patients still on same diet, treatment was begun with typhoid vaccine (50 to 100 million a dose) and at four-day intervals. The twenty-four hour sugar amount was again taken. After a period of three to four weeks, typhoid vaccine was discontinued and the sugar amount was taken at intervals. At the end of another four weeks, a return to vaccine was made and the sugar was again checked. The result of above treatment is given below:

Case I.—Patient admitted to hospital (October 20, 1912) in a semi-conscious condition and put to bed. Urine amount in twenty-four hours, 12 ounces; no casts; no organic acid; sugar present, per cent. not given. On October 24, under diet and soda bicarbonate treatment, urine had risen to 60 ounces; sugar at this time was 3.8 per cent. On the 29th sugar was 4.5 per cent.; urine 90 ounces; patient's mental condition, clear. On October 30, typhoid vaccine was started (50 million); slight skin reaction. On the 2nd of November, urine showed: sugar 3.1 per cent, no organic acid. On the 3rd and 7th, patient was given vaccine. On the 15th, urine showed: sugar 1.2 per cent. and general condition had so far improved that patient was allowed out of bed and all treatment was discontinued, except diet. On the 26th, sugar was less than 0.5 per cent. Left hospital on the 28th. On February 15, 1913, patient returned to hospital with return of symptoms; sugar at this time 5.7 per cent.

Case II.—Patient admitted to ward February 10, 1912, and on sugar being found in urine was placed on diabetic diet. Sugar 8.4 per cent.; weight, 86 pounds; no organic acids. February 25, sugar 3.2 per cent. March 7, sugar 6.1 per cent. On the 11th, patient was given vaccine (50 million), followed by slight skin reaction; 16th, vaccine. On the 20th, sugar 7.8 per cent.; weight 86 pounds; no organic acid. On the 26th, patient left the hospital and returned in forty-eight hours. Sugar on return, 5.9 per cent. On the 31st, vaccine (50 million); weight, 86.5 pounds. April 2, sugar 6.1 per cent.; no vaccine given during April. Sugar during April: 2nd, 6.1; 14th, 5.2; 24th, 4.0 (white bread given on this date). 30th, 3.0 per cent. On May 3, weight 86 pounds; vaccine resumed (50 million). May 6, sugar 3.5 per cent. May 7, vaccine 100 million. May 12, sugar 4.2 per cent. May 16, vaccine 100 million. May 21, sugar 2.4 per cent.; weight 92 pounds; vaccine 100 million. May 24, sugar 4.0 per cent.; weight 94.5 pounds. Treatment discontinued. Early in July the patient developed lung symptoms and tubercle bacilli were found in sputum.

Case III.—Patient transferred from surgical ward (January 30, 1913) after operation for hernia; wound healed; sugar 6.6 per cent; placed on diabetic diet. February 17, sugar 5 per cent. February 24, sugar 5.2 per cent. February 28, sugar 5 per cent. March 4, sugar 3.8 per cent. March 11, patient received 500 million typhoid bacilli; very severe reaction. March 14, sugar—a trace; no organic acids, weight 130 pounds. March 15, vaccine 50 million. March 20, sugar 3.8 per cent.; vaccine 50 million. March 25, vaccine 50 million. During April no vaccine was given. Sugar during April: (2nd, 3.8 per cent.; weight 130 pounds; 14th, 2.8 per cent., weight 131 pounds; 24th, 2.5 per cent., white bread allowed on this date; 30th, 3.2 per cent. On May 3 vaccine resumed—50 million. May 6, sugar 6 per cent., weight 131 pounds. May 7, vaccine 100 million. May 12, sugar 2.5 per cent., weight 127.5 pounds, vaccine 100 million. May 17, sugar 2.4 per cent., vaccine 100 million. May 21, sugar 6.2 per cent., vaccine 100 million, weight 128.5 pounds. May 26, sugar 5.4 per cent., treatment discontinued.

Case IV.—Patient admitted to ward (March 6, 1913) with beginning of gangrene of toe and history of long standing diabetes; sugar 6 per cent.; no organic acids; put to bed and diabetic diet given. March 12, vaccine 50 million. March 16, 50 million; no local reaction. March 19, sugar 3.8 per cent.; tubercle bacilli found in sputum. March 27, 50 million. April 1, slow advance of gangrene; no sugar or organic acids in urine. Patient died on April 5.

Special thanks are due Drs. O'Leary and Henderson of the House Staff who assisted me in this experiment.

## SUBPECTORAL ABSCESS.

### REPORT OF A CASE.

By C. LEGIARDI-LAURA, M.D.,

NEW YORK.

Acute suppuration under the pectoral muscles is not a common condition. According to v. Bergmann and Mikulicz ("Practice of Surgery"), of 1,080 inflammatory processes treated during the last ten years at the hospital in Eppendorf there were only twenty-six cases of suppurative processes of the chest. According to these authors the condition is almost always fatal on account of the extremely large surfaces through which infectious material may enter the body. Out of ten patients treated during the last six years at the above mentioned hospital only two recovered, whereas the others died of general sepsis (v. Bergmann and Mikulicz).

These authors do not clearly distinguish the two different clinical forms resulting from the location of the abscess either under the pectoralis major or under the pectoralis minor. But Tillaux ("Traité de chirurgie clinique"), who was the first author to describe deliberately the acute phlegmon of the subpectoral region, had already pointed out the differences of symptoms, course, and prognosis between the two conditions, and while he considers the former as a comparatively benign disease, he notes the anatomical perculiarities that make the latter one of the most dangerous conditions.

The pectoralis minor is firmly attached to the clavicle by the aponeurosis of the subclavian muscle; between the pectoralis minor and the chest there is a space occupied by cellular tissue; this space communicates freely with the neck beneath the clavicle.

This is why this deeper abscess cannot finds its way externally, and why local symptoms do not appear clear and early.

Whether the suppuration be of the one or of the other form, it can be a result of cellulitis, but usually it has its starting point in the lymphatic glands of the axillo-pectoral region, or in the subclavian nodes. When the infection affects the glands near the coracoid process or the subclavian nodes, pus may collect over the costocoracoid membrane and clavipectoral fascia, and form a subpectoral abscess. Indeed the diagnosis is clear when a bulging of the pectoral region is present; but this is a late symptom. At the beginning of the disease and without enlargement of the axillary glands, and especially if the pus has formed beneath the pectoralis minor muscle, the diagnosis may be perfectly obscure.

The abrupt onset, the usually high temperature, and the general condition of the patient may lead one to think of some internal condition, while the pain, which is usually dull and more or less diffuse to the side of the chest, together with more or less difficulty in breathing, may suggest pleurisy, or perhaps pneumonia. In these cases, before the practitioner has availed himself of a blood examination, before any local fact suggests a suppuration, the condition is likely to be serious. It is septicemia, in fact, that makes the acute suppurative process under the pectoral muscles a very dangerous condition; and while the operative procedure is very simple by itself—so simple, indeed, as to be within the means of every practitioner—the necessity of an early diagnosis and a prompt interference is all the more important.

The case I am reporting is one of the most characteristic, and has two clinical peculiarities: (1) The predominance of the general symptoms at the very beginning. (2) The formation of subpectoral abscess by suppuration of the subclavian nodes without suppuration of the axillary glands, and as a complication of a simple excoriation of the skin of the hand. Finally, we can also note that the lymphatic system of the skin of the hand drains into the lymphatic nodes of the axilla; so that it ought to be expected that an infection of the skin of the hand should induce infection of the axillary glands, and only secondarily infection of the pectoral, subpectoral, and subclavian nodes. In my case we must admit that infection has primarily taken place in a latent form in the axilla, and secondarily but more acutely in the subclavian lymphatic glands.

Case.—A. V. 28 years old, laborer, had typhoid fever at the age of 12. Nothing else of importance in his personal history. On July 21, 1913, while at his usual occupation (stone breaker) he received two excoriations, apparently of no account, on the dorsal surface of the right thumb and index finger. He did not pay any attention to the superficial wounds and continued to work. The next day he went to his work as usual, but in the afternoon began to feel pain in the arm and right side of the chest; nevertheless he went through his regular day's work; he was not able to get out of bed the next day, but for three more he did not ask for any regular treatment. He looked very ill, and complained of severe pains in the arm and axilla, headache, and fever; in fact, his temperature was about 104° F. The skin of the dorsum of his right hand had two small excoriations from which one or two drops of a yellowish pus could be obtained. The forearm and the arm were not swollen, there was no redness of the skin and the lymphatic glands of the elbow and axilla could hardly, if at all, be felt enlarged. In fact there was no local condition, apparently, to account for the high temperature of the patient and for his sickly appearance; so that at first sight one could have hardly thought the fever and the general discomfort of the patient were dependent upon the complications of the superficial wounds of the hand. But a careful examination of the patient failing to show any other condition capable of explaining the general symptoms, I satisfied myself with a diagnosis of septicemia from infected wound of the hand I did not see the patient for five days more, when I was again called in, and found him in a semistuporous condition, complaining of dull pain in the right and anterior side of the chest; the pain being more intense during the respiratory movements.

The chest wall was tender, the patient was restless and complaining of insomnia, obstinate headache, and profuse perspiration; he was not able to raise the arm on account of pain. There was no sign of suppuration in any part of the lymphatic system, nor in the cellular tissue of the region. The excoriations above mentioned appeared healed up. Percussion showed that the right infraclavicular region was perhaps a little duller than on the left side, but auscultation was normal. While I suspected some purulent focus as the cause of the trouble, I could not positively locate it. I injected hypodermically a full dose of antistreptococcus serum. The next day the patient looked brighter and the temperature dropped to 100° F. in the morning, only to reach 103° F. again at night, and a vesicular eruption appeared on the chest, especially on the right side. The next morning the temperature was 103°, the skin over the right pectoral region appeared tense and a little edematous, so I decided to make an incision. After painting the infraclavicular region with tincture of iodine, I made a two inch incision parallel to and about two inches below the clavicle, comprising the skin and subcutaneous tissue, and then the pectoralis major and minor muscles. As soon as I reached beneath the latter, a large amount of pus, "bonum et laudabile," rapidly flowed out of the incision, while a probe showed the presence of a large and deep pus-cavity pointing under the clavicle toward the root of the neck. Having complied with the urgent necessity of evacuating the pus, I simply introduced a large rubber drainage tube into the cavity toward the root of the neck behind the clavicle and covered the region with a well padded aseptic dressing. No other intervention proved necessary as the patient recovered uneventfully in about ten days after the operation.

## REFRIGERATION WITH ICE IN THE TREATMENT OF INTERCOSTAL NEURALGIA.

By PASCAL ROMEO, Ph.B., M.D.,

KANSAS CITY, KANSAS,

FORMERLY INTERNE IN THE PARIS HOSPITALS.

F. M., 30 years old; married; Croatian. Parents living and in good health; no syphilis; no tuberculosis; never used alcohol, nor tobacco to excess. Two and one-half years ago he started to work in a refrigerator of a packing house in Kansas City, and during the first six months was in good health. At this time he was wounded with a sharp knife, two inches below the right breast, along the mammillary line, but the wound did not penetrate the cavity. One week later he resumed his usual work; a short time afterward he felt, particularly in damp weather, a slight painful sensation, circumscribed within the region where he had been wounded. The character of the pain was a little sharp, coming at long intervals, mostly at night, and lasting only a few seconds. Within four months the pain had increased to such intensity that it became almost unbearable. The character of the pain was first paroxysmal, lancinating, incisive, and with burning sensation; sometimes was persistent and radiating to the right clavicle and below the right nipple, confined within the external axillary line and the parasternal of the right hemithorax. The pain, up to this time, never had been irradiating to the dorsal region, and the point of its maximal intensity had always been in the region where the patient had been cut. Two months later the topography of the pain was as follows: At the sternum, in correspondence with the fifth costal cartilage, and at the axillary line at a level of the spinal apophyses of the sixth and seventh cervical vertebræ. Sensibility on the affected side was increased. Temperature of the right axilla was always from two to three-tenths of a degree above that of the left. The semicircumference of the right thorax at the mammillary level was 16 inches; left 17. Frontal headache on the right side was very severe. Hyperhidrosis hemifacialis of the same side was also one of the most

troublesome symptoms. Examination of the respiratory organs did not show any special condition for consideration. The examination of the heart disclosed an anemic murmur, systolic in time, heard at the left base, not transmitted. There was no evidence of hypertrophy or dilatation. The pulse showed a low tension, 68 per minute. Dyspeptic conditions were present; the stools were hard and passed only every two or three days; urine normal. Weight before illness was 190 pounds; now, after two years, is 150 pounds. Anemia, loss of strength, anorexia, dyspepsia, and excitability were prominent in the clinical picture.

The patient could not be made to believe that he had a chance to recover. Nothing would give him relief; nothing could make him happy. He presented a characteristic neurasthenic appearance; always angry for no apparent reason, realizing the fact and having no will power to restrain himself. Out of work all the time. He had tried all kinds of treatment, but any relief obtained never lasted more than 24 hours. On account of the general health conditions I deemed it advisable to give a tonic treatment, in connection with the local one. I gave the phospho-arsenite of iron hypodermically. Locally I had tried nearly every remedy, but always without any permanent relief, although the general conditions were improving to a certain extent. Patient had been taking too much morphine, and I was obliged, twice during the treatment, to give him relief by this means. One evening the patient came to my office as usual. After treating him in the manner before stated I painted the painful area with tincture of iodine, freshly prepared, and made according to the directions of the United States Pharmacopœia. After a few minutes patient developed in the affected side a burning hyperesthesia, covering all right hemithorax, face, and head. Nothing in the left side. Frontal headache appeared worse than usual; I had tried nearly all usual remedies with very little results.

Having no other means at my disposal, I anointed the region with common vaseline in order to prevent a possible sphacelus *a frigore* of the same. I then wrapped a large piece of ice in a towel and applied it to the affected part by rubbing. I made fractional refrigeration as the patient could not stand the same continuously. Twenty minutes later he felt relieved and went home. That night he had a very good sleep. The following day I saw him at my office and he was feeling exceptionally good and was apparently well. Now, after more than five months, the patient has never had a recurrence of pain; is working every day, and has gained fifteen pounds. At my advice, however, he has given up the work he had been doing previous to his illness.

Intercostal neuralgia is generally attributed to cold, anemia, intoxication, syphilis, and is also due to local causes, as pleural lesions, as well as tuberculosis of the lungs, rib fractures, aortic aneurysm, Pott's disease, and in women to cancer of the breast; sometimes it may be due to reflex causes, as in cardiopathy, gastropathy, and also in uterine pathological conditions. The main symptom is the persistent pain, unilateral, more frequently at left side. Sometimes respiration, particularly a deep inspiration, increases the pain. Valleix describes three painful points proper of intercostal neuralgia; sternal, vertebral, and axillary.

The treatment recommended is the same as for all neuralgias in general. To control the pain local revulsives are of use; tincture of iodine, cantharides, veratrine ointment, 3 per cent., etc., are commonly employed. Ethyl chloride, chloroform, morphine, cocaine, and the like are largely used.

The causal treatment, when the cause can be disclosed, is the rational one, as under the same we always obtain good results. So, in case of neuralgia from malaria, quinine renders us the best service; in syphilis specific treatment controls the conditions very well; in rheumatic subjects the salicylates in general do the work, etc.

The treatment of the general conditions, when the same are in the clinico-pathological picture, should be cared for in connection with the topical treatment. In severe cases the application of constant electric currents has rendered good services. (Positive pole on the dorsal column, negative on the painful area.)

In 1888 the well known medical clinician of Rome, Baccelli, at the Congress of Internal Medicine, introduced a new method of treatment of neuralgias. The method consisted in practising local injections with one or two per cent. of carbolic acid solution, preferably along the course of the nerve, in doses of one to ten c.c. *pro die*. This method had its hour of glory, to the point of being considered as a specific at home as well as abroad. The method really has worked very satisfactorily in many cases and reports to that effect come from many practitioners from time to time. I tried this method in the present case, but did not obtain any satisfactory results. Hydrotherapy here found also a good application. When all remedies have failed surgery is the last resort. The same may be circumscribed to the following operations: (1) Compression of the nerve with the fingers or by means of an apparatus *ad hoc*. (2) Bloody or unbloody stretching of the nerve. (3) Neurotomy. (4) Neurectomy or resection of a nervous tract.

As far as etiology is concerned in my case I would say that cold, caught in refrigerators of a packing house, is to be blamed. This statement is corroborated by the fact that intercostal neuralgia occurs more frequently in the left side than in the right. I believe that cold alone would perhaps not have determined a pathological condition such as appeared in my patient. He had been doing the same work for six months before receiving his wound and always in the best of health. In this case one treatment alone was sufficient to cure a condition of two years' standing.

This case alone, treated successfully in the manner above mentioned, does not authorize me as yet to claim a new method for treating intercostal neuralgia *a frigore*. However, I feel confident that a further trial will prove my statement to be correct and satisfactory.

346 North Fifth Street.

---

**Gonorrhea and Suppurative Disease of the Uterine Adnexa.**—H. Schottmüller and W. Barfurth made a careful bacteriological examination of the pus in 79 cases of suppuration in the uterine adena. There were found gonococci in 6.3 per cent.; streptococci and staphylococci in 17.8 per cent.; miscellaneous organisms in 25.3 per cent.; and anærobic organisms in 35.4 per cent. of the cases. The cultures were sterile in 15.2 per cent. of the cases. The authors conclude from these findings, in agreement with Döderlein, that gonorrhea does not play an important rôle in the production of adnexal suppuration in women. Septic infection is a more dominant factor.—*Beiträge zur Klinik der Infektionskrankheiten und zur Immunitätsforschung.*

**Congenital Eye and Heart Defects.**—D. G. Greenfield reports the case of a male, aged 11 years, who was a full-time child weighing 1 pound 15 ounces at birth. His mother has had no other children or miscarriages. He had convulsions as an infant and at the age of 8 months developed a "cataract"; he has always been deaf and can hear nothing with the right ear and very little with the left. Since the age of 5 years he has had a left otorrhea. He can read with the left eye, but the right eyeball is small. He also has a congenital heart lesion. There is no evidence of congenital syphilis, and the author gives no history of anything to account for the condition.—*Proceedings of the Royal Society of Medicine.*

## REPORT OF THE SURGEON - GENERAL, UNITED STATES NAVY.

THE Surgeon-General of the U. S. Navy has just issued the annual report which on the whole goes to show that the health of the personnel has been good during the fiscal year 1913. The prevalence of certain diseases has abated, while some diseases have exhibited increased occurrence. Animal parasitic infections have increased, a result chiefly due to the greater amount of interest taken in hookworm disease and the larger number of examinations for the parasite thereof. The rate for pneumonia has been decreased at the training stations and shore stations, but the force afloat showed an increase over the previous year. The decrease of this disease in the training and shore stations is attributed to the prevention of overheating of living and working spaces. Attention is drawn to the great success of antityphoid inoculation, the fleet surgeon of the Atlantic fleet going so far as to state that the administration of the prophylactic has practically eradicated typhoid from the fleet and that this serious menace to the health of the navy seems to have passed away. A slight reduction in the number of cases of malaria is noted and salvarsan has been used in the treatment of a small number of cases with encouraging results. Tuberculosis has decreased considerably. Diseases of the nervous system showed a decrease, but diseases of the digestive system have increased since 1911, an increase which on analysis is found to be due to increased incidence of appendicitis and tonsillitis.

Venereal diseases have decreased in a satisfactory manner. On the subject of prophylaxis the report says: "From a military standpoint it has become imperative that prophylaxis for venereal disease shall be properly employed. It should be arranged so that if the men, after being thoroughly instructed in personal hygiene and the advisability of avoiding venereal exposure, persisted in wilfully seeking illegitimate intercourse they could procure an effective prophylactic to carry with them and apply within six hours after exposure, should this take place." The bureau emphasizes its recommendation that those who are disabled by reason of venereal disease should have their pay checked while on the sick list. Attention is drawn to the fact that this practice has been in vogue in the army for some time with satisfactory results.

The sanitary conditions and measures afloat are dealt with at some length, but can be only briefly referred to here. Ventilation of the forward compartments of battleships is a problem that has yet to be successfully solved. According to the report, the combined heating and ventilating system is subject to the criticisms stated in last year's report, namely, low relative humidity of air, failure to maintain an equable temperature in all compartments, and dust and insects not removed from the air before distribution. Louvers in most compartments are near the ceiling, resulting in poor circulation of air, since in cold weather the warm air is not delivered into the cooler stratum at the lower level and the normal difference of temperature between the deck and ceiling is increased. Garbage disposal on battleships is another matter that demands serious consideration. As a rule, at sea, the refuse is dumped overboard or burned in the fireroom. When in port it is usually collected by lighter once daily and dumped at sea, proper storage of the garbage for twenty-four hours being a serious problem. The report strongly recommends that garbage incinerators be installed on all ships as rapidly as possible. The character of the vessels used as transports is severely commented upon in the report.

The question of competitive athletics is again discussed and the conclusion formed that general indulgence in athletics is desirable, and the mental relaxation secured in this way is even more complete and more profitable than that obtained by prescribed physical drills, and the ideal to be desired is for every man to take an interest in some form of physical diversion other than the routine exercises which are required. As in the army so in the navy, there is a considerable shortage in the hospital corps and some revision of entrance regulations is necessary in order to render the service in the corps more popular.

## OPERATIVE INJURIES OF THE VAGUS AND INTERNAL JUGULAR.

THERE seems to be a tendency on the part of many expert surgeons to be indifferent to the danger of injuring the vagus and internal jugular when operating for benign or malignant growths of the neck. Roswell Park (*Annals of Surgery*, August, 1895) found in the literature reports of 15 cases of accidental injury of the vagus and 50 where the nerve had been sectioned, resected, or caught in a ligature during the progress of an operation. Among the 15 accidental cases 11 patients died, 2 recovered, and in 2 the result was unknown; while of the 50 in which the nerve was injured during operation, 21 died, 27 recovered, and in 2 the result was unknown. Park evidently believes that injury to the nerve played no very important part in causing the deaths, for he stated that "It is impossible to say that in any instance death was due to injury of the nerve," and "the preponderance of testimony is in favor of the comparative safety of attacking this nerve when involved in disease, and when too much other operating is not necessitated by the

condition which has caused the operative attack." These conclusions were reached in spite of the fact that pulmonary edema, gangrene of the lung, or unusually rapidly developing pneumonia occurred in a considerable number of cases.

Since then the subject has been discussed many times, especially by German authors. One of the most notable of their contributions is that of A. Reich, published in the *Beiträge zur klinischen Chirurgie* in January, 1908. His article is based upon the study of 83 cases, including 11 accidental wounds, 44 operative sections or resections, and 28 irritations, traumatic or operative. Bérard and Chalier (*Lyon Chirurgical*, November, 1912) utilized his material in connection with reports of their own cases and others found in the literature, and thus collected histories of 17 traumatic wounds of the vagus, 54 operative sections or partial resections and a large number of irritations, of which they report only the most interesting. The 17 traumatic wounds were complicated by injuries of other nerves (single or multiple) 13 times, of the carotid twice and of the internal jugular once. Clinically, allowing for shock, observed in some cases, cardiac troubles were absent or of small moment and transitory. They consisted in lowering of the blood pressure and acceleration of the heart beat. Respiratory troubles, on the contrary, were practically constant. There was usually an immediate paralysis of the vocal cord and many had cough and dyspnea. Some had pneumonia, usually fatal, and always situated on the side of the nerve sectioned. Dysphagia was observed in some cases, while often many of these symptoms were combined in one patient. There were 7 deaths (asphyxia 2, pneumonia 5), 7 survived but sometimes with vocal-cord paralysis and other symptoms, while in 3 cases the result was unknown. Tachycardia sometimes persisted for a long time but finally always subsided.

Among the 54 operative sections and resections there were found as concomitant lesions partial resections of the jugular 32, ligature or partial resections of the carotid 28, sections or resections of the sympathetic 7, and occasional injuries or ligations of other vessels or nerves. There were 21 deaths. In these 54 cases Bérard and Chalier studied the effect (1) on the heart, (2) on the respiration, and (3) on the esophagus and stomach. The cases where a competent assistant noted the state of the heart and pulse during the entire duration of the operation proved the similarity of action on the heart of man and animal of unilateral vagotomy. They found that this causes immediate marked acceleration of the pulse but never disquieting cardiac accidents. Tachycardia, often very slight, attains only rarely 120 or 130 pulsations to the minute, and disappears ordinarily in some hours, or at most in some days. Immediate effects of vagotomy upon respiration seem quite inconstant and of little moment, though recurrent nerve paralysis is the rule. "Outside of the paralysis of the corresponding vocal cord, section of the vagus in the neck does not start any immediate respiratory trouble." More or less early secondary respiratory manifestations, however, appear to be very frequent, but divide themselves into two classes of entirely opposite prognostic significance. Some are not of great moment, for they are similar to those frequently observed in the surgery of the neck. Such are laryngitis, tracheitis, and bronchitis, which are sufficiently explained by the location and nature of the operation, without its being necessary to search for an outside influence such as injury to the vagus. The others, more grave, consist in the pulmonary complications, properly so called, whose relations with the nerve it is important to determine. Seven of the 54 cases may *a priori* be considered as examples of vagus pneumonia. In three cases the pneumonia was on the side of the nerve sectioned, in one on the opposite side, and in three the lesion was bilateral. All but two of these cases they believe may be sufficiently explained by the general nature of the operation, and depend in no wise upon the vagotomy. Strange as it may seem, they also state that it appears difficult to maintain, in the case of human pathology, that there is a true vagus pneumonia, and, further, one should not accuse paralysis of one vocal cord, which inevitably accompanies vagotomy, of especially predisposing to pulmonary complications. Tuffier, however, believed his case of pulmonary gangrene to be due solely to the resection of the vagus on the same side during the course of an operation for carotid aneurysm. The influence of unilateral vagotomy on the digestive apparatus in man is still more doubtful than is its influence on the heart and respiration. Few authors mentioned digestive complications at all, and those usually distinctly stated that there were none. From these studies of the effect of vagotomy upon the heart, respiration, and digestive apparatus. Bérard and Chalier conclude that "unilateral vagotomy, right or left, upon a nerve healthy or degenerated, has not by itself any gravity."

Operative irritations of the vagus also affect heart, respiration, and digestive system. There may be circulatory disturbances ranging from simple diminution of blood pressure with slowing of the pulse to the arrest, temporary or final, of the heart. Immediate effects upon respiration consist often only in attacks of fitful cough, with or without dyspnea. With a further degree of irritation respiration becomes embarrassed, then arrested sharply, to start up again ordinarily after some forced, jerky inspirations; though sometimes the respiratory pause is final. If grave results do not immediately appear from its inhibitory action on the heart and respiratory apparatus, none are to be anticipated; for vagus irritation plays no part predisposing to late pulmonary complications. Digestive disturbances are confined to transient nausea and vomiting and are never serious. Five deaths are reported in the literature from vagus irritations, but, again, Bérard and Chalier question its sole responsibility for the fatal outcome and, while counselling care in the avoidance of this nerve, rather make light of the chance of there being any serious results following its accidental injury. Reich, on the other hand, who had one fatal case and several others desperately close to it, considered that the danger from irritation of this nerve is considerably more grave than that from section or resection.

Bérard and Chalier finally conclude that the surgeon should not be "hypnotized" by the pneumogastric, and state that "section or the frank resection of this nerve is not dangerous; it will be better to have recourse to it in the cases of adherence or neoplastic invasion than to attempt to free the nerve, thus risking its irritation, or to prolong beyond measure an operation already long and shocking. One should abstain in all cases, even if it produces an abundant hemorrhage, from pinching or tying in the dark, in the fear of seizing also the nerve and producing a reflex syncope which might be very serious."

P. Guibal (*Revue de Chirurgie*, July, 1913) formerly shared with the majority of surgeons the firm conviction that patients are not subjected to any great risk when the operator resects, on one side of the neck, either the internal jugular, the pneumogastric, or both of these structures at once. He reports a case which cured him of this optimism and which is well worth the attention of all who have the impression that jugular or vagus may be resected with impunity. In dissecting cancerous glands of the left side of the neck, the jugular was soon found to be involved by the growth, was divided near its lowest point between two ligatures, and vein and glands were rapidly dissected upward. At one point the vagus traveled directly through the cancerous mass. A clamp was applied above this point, nerve and jugular were sectioned, and the involved portion of nerve was resected. At the moment of putting a ligature on the central end of the vein it tore but was quickly seized by a forceps. Because of the depth to which the jaw of the forceps reached, it was impossible to see if the vagus was caught at the same time as the vein; but there was no immediate evidence of trouble and the anesthesia continued to be normal. The carotid was seen to be uninjured. A tracheotomy was then done, preparatory to a subsequent laryngectomy for removal of the primary growth. A few hours later the patient was found to have pneumonia affecting the lower half of the left lung and beginning paralysis of the right half of the body. The following morning hemiplegia was complete, there was incontinence of urine and feces, and coma was absolute. The patient died within less than forty-eight hours after operation. Autopsy could not be obtained. Guibal believes that the section of the pneumogastric was the principal factor in the development of the pulmonary lesions and that the hemiplegia was due to some anomaly in the intracranial circulation. In support of this latter conclusion he cites a number of instances where autopsy after jugular ligation revealed incomplete development of intracranial venous channels or of the other jugular.

This résumé of some of the most important contributions to the literature should make it clear that operative injuries of the pneumogastric or ligation of the internal jugular may cause death; that while it is true that the vast majority of such cases survive, it is impossible to foretell the outcome in any given case; and that extreme care should supplant indifference in handling these structures.

## INFLUENCE OF THE INTERNAL SECRETIONS UPON FEMALE CHARACTERISTICS AND FUNCTIONS.

In a paper read before the Clinical Congress of the Surgeons of North America, at Chicago, on November 14, Roswell Park said that the internal secretions, so often spoken of as hormones, exercised an apparently controlling influence on many of the organs and functions, and this not alone on the ordinary body functions, but on the nutrition and regulation of individual organs and their particular activities even to the extent of becoming responsible for the development of certain mental traits or personal characteristics which make or mar the individual and thus affect both his physical and intellectual welfare. The importance of the internal secretions is beginning to be recognized and further studies in this direction with consequent discoveries bid fair to revolutionize the practice of medicine. In every country of the world investigations with regard to this question are going on and a more intelligent comprehension of the part played by the internal secretions in developing and influencing the bodily functions and mental characteristics is slowly but surely filtering through the consciousness of the medical profession at large.

On November 6 a particularly interesting discussion took place at a meeting of the Section of Obstetrics and Gynecology of the Royal Society of Medicine in London (*Lancet*, November 22, 1913). W. Blair Bell of Liverpool read a paper dealing with the relation of the internal secretions to the female characteristics and functions in health and disease. He first pointed out that from a broad standpoint femininity itself is entirely dependent on the internal secretions acting in correlation. In considering the more purely morphological and physiological aspects of the matter, the production of the female characteristics, primary and secondary, was traced to the internal secretions, and this statement was supported by facts. The paper dealt with the whole question exhaustively and was a contribution of some note to the literature concerned with the internal secretions.

Louise McIlroy of Glasgow continued the discussion and in conclusion gave it as her opinion that it was a happy augury for future work that there should be so much collaboration between the laboratory worker and the clinician. She drew attention to the fact that much confusion as to the function of the ductless glands arose from want of proper comparison of the variation in different species of animals and of the human subject. The secretory organs modified sex development, but did not cause the assumption of secondary characteristics, as these would probably be found to be due to cell development in very early embryonic life.

---

### The Insanitary Waiting Room.

In this age of advanced sanitation, in which the gospel of health is being continually preached, it is curious to note how frequently its tenets are disregarded. This is especially the case in rural districts, where even such mighty corporations as railroad

companies are constant sinners. Attention is drawn to this fact in Public Health Reports, October 10, 1913, in which it is pointed out how seldom the waiting rooms used by passengers are kept in a wholesome sanitary condition. Such places are generally the loafing haunts of the unemployed, who aid in vitiating the air and not uncommonly spread the germs of infection by promiscuous expectoration. Further, the toilet arrangements are usually deplorable and lacking in ordinary decency as well as sanitary precautions. The bad condition of toilets attached to waiting rooms is perhaps in the majority of instances not due to the negligence of the transportation companies, but is owing rather to the want of public conveniences which compels many to use the waiting room toilets. The scarcity of public conveniences in America installed and operated by municipalities or public bodies is a blot on the sanitary fair fame of the cities as well as of the rural districts of the country. In all parts of Great Britain and in many parts of Europe municipal lavatories are maintained in cities and towns, in which at a very small cost a person can have the use of a scrupulously clean toilet and is also afforded facilities for washing. The plea for sanitary waiting rooms in America will find an echo in the hearts of all those who travel in any part of this continent.

### Unbaked Eugenic Legislation.

At a recent meeting of the Milwaukee, Wis., Medical Society, it was agreed that for the prescribed fee of $3 it was impossible for physicians in the State properly to conduct the medical examinations required under the new marriage law before the issuance of a marriage license, and a committee was named to lay the matter before the State Board of Health. The law, which went into effect on January 1, 1914, provides that all applicants for marriage licenses must prove their physical fitness by the production of a physician's certificate, and prescribes a fee of $3 to be paid to the physician, though the cost of performing all the necessary tests is very much more than that amount. Unless arrangements can be made by which the tests can be carried out by the State Department of Health it would seem that weddings in Wisconsin may be very much decreased. The law makes it a felony for any couple to leave the State and be married in an adjoining State. The danger of such a law lies in the possibility that it may prove a boon for those who are willing to issue a certificate for the small fee without making the necessary and complete examinations of the applicant. Before ignorant law-makers and sensational clergymen begin playing with eugenics it would be advisable for them to inform themselves regarding this new science—what it is and how much or how little is to be hoped from it.

## News of the Week.

**Civil Service Examinations.**—Competitive examinations for the positions mentioned below will be held in various cities throughout New York State on January 17, 1914. Applications blanks may be obtained before January 7 by addressing the State Civil Commission, Albany, N. Y. No applications received at the office of the Commission after January 9 will be accepted.

Physician, regular. This examination is intended to provide eligibles for the position of assistant physician and other medical positions of similar grade in the State hospitals, etc., at an entrance salary of $1,200, increasing $100 each year to $1,600, with maintenance. A vacancy exists in the position of resident at the West Haverstraw Hospital for the Care of Crippled and Deformed Children.

Woman physician in State hospitals and institutions. A vacancy exists in the position of resident at the Western House of Refuge, Albion, N. Y., at a salary of $1,000, increasing to $1,200 per year and maintenance. Open to licensed medical practitioners of New York State, of either regular or homeopathic schools, with one year of hospital work or three years general medical practice.

Medical Inspector of Factories. Open to licensed practitioners of New York State, both men and women. Appointments of a Chief Medical Inspector at $3,500, and two medical inspectors at $2,500, one of these to be a woman, will be made.

Coroners' Physician, East Side, Monroe County, at $150 per annum. Candidates must be legally licensed medical practitioners and residents of Monroe County. They will not be required to appear for written examination, but will be rated on experience and personal qualifications as shown by sworn statements to be submitted.

**Broome County Tuberculosis Hospital.**—The Board of Supervisors of Broome County, New York, by a vote of 23 to 5, has decided to take over the Mountain Sanatorium property of Binghamton City Hospital, and hereafter will conduct the institution as a county tuberculosis hospital. The property comprises thirty acres of land and is valued at $10,000.

**Dr. Henry Winston Harper,** M. D. University of Virginia, 1892, and professor of chemistry in the University of Texas since 1894, has been made first dean of the Graduate Department of the University.

**Post-Graduate Hospital.**—The annual report of the New York Post-Graduate Hospital gives the number of patients treated in the hospital during the year as 7,518 and the total number in all departments as 53,308, of which 4,253 were free cases. There was a large increase in the number of physicians taking courses of study at the school.

**New York's Good Health.**—For the first eleven months of the year the following vital statistics have been given out by the Department of Health of New York City. The total number of deaths reported was 67,694, giving a death rate of 13.78 per thousand of population, as against a total of 66,714 and a rate of 14.10 for the same period of 1912. Among the causes of death showing decreases in number are tuberculosis of the lungs, 305; other forms of tuberculosis, 26; diarrheal diseases in children under five years of age, 609; typhoid fever, 149; lobar pneumonia, 146; measles, 76; acute bronchitis and bronchopneumonia, 18. The causes of death showing increases are organic heart disease, 447: diphtheria and croup, 175; whooping cough, 133; influenza, 83; cancer, 28. Not a single death from smallpox was reported.

**Another Centenarian.**—"Granny" Deese, probably the oldest inhabitant of Alabama, celebrated her 107th birthday at her home in Mobile on December 27.

**Crocker Laboratory.**—The work of cancer research was begun on January 1 by the staff of the George Crocker Special Research, Columbia University, in the new Crocker Laboratory at 116th street and Amsterdam avenue. The building, erected by the university solely for research work, is admirably equipped and provides ample room for a large staff of workers. Dr. Francis Carter Wood, director of Cancer Research, is in charge of this department of the university.

**Cancer Clinic.**—At the General Memorial Hospital for the treatment of Cancer and Allied Diseases, 106th street and Central Park West, New York, Dr. William B. Coley and Dr. William A. Downes will hold a clinic for the diagnosis and treatment of operable and inoperable malignant disease, on Thursday afternoons, at 2:30.

**Gibbs Prize.**—The committee in charge of the Edward N. Gibbs Memorial Prize Fund announces that the selection of the worker under the fund for the year 1914 will be made about February 1 and requests that candidates for the award send in their applications, together with a statement of their fitness to pursue the investigations, including the laboratories in which they have studied, and any researches conducted by them, so that the committee may be guided in its selection. This fund was established by the wife and daughter of the late Edward N. Gibbs, and the income, amounting to about $500, is used in aiding investigations into the cause and treatment of diseases of the kidney. The recipient is chosen annually. Applications may be sent to the Committee of the Gibbs Memorial Prize Fund, New York Academy of Medicine, 17 West 43d street, New York.

**National Conference on Race Betterment.**—This conference will be held at Battle Creek, Mich., on January 8 to 12, 1914, under the presidency of Dr. Stephen Smith of New York. Morning and evening sessions will be held at the Battle Creek Sanitarium, for which a long and interesting programme has been prepared. Moving picture and lantern slide exhibitions have been arranged, and there will also be exhibits from the National Child Welfare Committee of New York City, the Association for Study and Prevention of Infant Mortality of Baltimore, and the Michigan State Board of Health and Tuberculosis Society. An ample fund for the maintenance of the conference having been provided by a friend of the Race Betterment Movement, there are no dues or assessments in connection with membership in the conference, and it is also possible to offer entertainment without charge to 200 officially invited guests at the Battle Creek Sanitarium. Further details may be obtained by addressing the secretary, Miss Emily F. Robbins, Battle Creek, Mich.

**Charitable Bequests.**—The Memorial Hospital, Pawtucket, receives a bequest of $10,000 by the will of Mrs. Sarah Goff Steele of that city.

Bequests of $5,000 each to St. Vincent's Hospital, Sanitarium Gabriels, the Servants of Relief of Incurable Cancer, and Seton Hospital, New York, are made in the will of Francis Higgins of New York, who died on November 15.

Mt. Sinai Hospital received $10,000 and the Montefiore Home, New York, $2,500 by the will of Samuel H. Spingarn of this city.

The Hahnemann Hospital, New York, receives, subject to the life interest of certain beneficiaries, a share in the residuary estate of Mrs. E. M. Raymond of this city, who died on November 27. The amount of the bequest is not stated, but is said to be large.

A bequest of $5,000 to the Nyack Hospital, Nyack, N. Y., is contained in the will of Mr. N. B. Cushing of that city, who died a few weeks ago.

By the will of the late Miss Susan Gorgas of Philadelphia, the sum of $5,000 is bequeathed to the Chester County Hospital, and the residue of the estate to the Roxborough Home for Indigent Women, a charity founded and largely supported by the decedent.

By the will of the late George W. Lees of Philadelphia, an estate of $9,000 is left in trust to brothers and sisters, on whose death the sum of $5,000 is bequeathed to the Methodist Hospital.

**Diphtheria Closes Hospital.**—The Nassau Hospital, Mineola, N. Y., was temporarily closed on December 14, because of an outbreak of diphtheria among the nurses of the institution.

**For London Hospitals.**—By the will of Sir Julius Wernher, the South African diamond merchant who died in 1912, the London hospitals benefit to the amount of $2,325,000.

**The Panama Exposition.**—Medicine and Surgery are to receive special attention at the Panama-Pacific Exposition at San Francisco in 1915. One feature will be a presentation of the methods with which the mosquito was fought, the application of the especially devised sanitary process by which Dr. Gorgas and his men were victorious in their struggle with malaria and the deadly fevers of the tropics. Another interesting medical exhibit will be the Emergency Hospital, the equipment being provided entirely by exhibitors. This will be under the direction of Dr. R. N. Woodward, of the United States Public Health Service, and will include the very latest and finest specimens of hospital equipment. It will be used for the emergency treatment of visitors to the exposition.

**Care of Feeble-Minded.**—A recent report of the New York State Board of Charities places the number of idiots and feeble-minded persons in need of care in the State at about 30,000, and adds that there are present available accommodations for about 4,000 only. The report urges the building of additional institutions as soon as possible.

**Radium Work at Harvard.**—Dr. William Duane, formerly a coworker of Mme. Curie, has been appointed assistant professor in the division of physics in Harvard University, where he will study the physiological action of radio-active substances.

**For Radium Institute.**—The taking over by the United States Government of all the deposits of radium-bearing ore in this country, and the establishment of a Federal institution for the production of radium and its distribution to physicans for the treatment of cases of cancer, has recently been suggested.

**Travel Study Club.**—The physicians who made a study tour of Europe last year under the chairmanship of Dr. William B. De Garmo of New York, have organized into a permanent body to be known as "The Travel Study Club of American Physicians." At a recent meeting a constitution and by-laws were adopted, and the following officers were elected: *President*, Dr. Louis Livingston Seaman, New York; *Vice-Presidents*, Dr. W. B. De Garmo, New York; Dr. Edward B. Heckel, Pittsburgh, and Dr. Howard Van Rensselaer, Albany; *Secretary-Treasurer*, Dr. Richard Kovacs, New York. The club plans a tour in 1915 to the

meetings of the American Medical Association, the San Francisco Exposition, Honolulu, the Philippines, China, and Japan.

**Cold Storage Signs.**—The State Commissioner of Health of New York recently issued a regulation providing that in future cold storage goods in New York State must be sold and advertised as such. All persons and firms retailing cold storage products must display prominently a card bearing the notice to consumers that cold storage goods are sold on the premises. The regulation also makes it unlawful to remove from packages containing foods from cold storage the stamps showing when the articles were placed in storage and when they were taken out.

**Hospital Ship to Mexico.**—The U. S. Hospital ship Solace has been ordered to Mexican waters in order to care for the sick on the battleships stationed there.

**Reward for Triplets.**—The Board of Supervisors of Orange County, Cal., has made a standing offer of a reward of $100 for each set of triplets born in the county.

**Medical Society Elections.**—St. Clair County (Ala.) Medical Society: Annual meeting at Odenville on December 4. Officers elected: *President*, Dr. J. W. Woods, Springville; *Vice-President*, Dr. R. L. McLellen, Easonville; *Secretary-Treasurer*, Dr. J. R. Chandler, Odenville.

Jefferson County (Ark.) Medical Society. Annual meeting at Pine Bluffs on December 3. Officers elected: *President*, Dr. T. W. Woodul; *Vice-President*, Dr. E. C. McMullen; *Secretary-Treasurer*, Dr. J. T. Palmer.

Jackson County (Ark.) Medical Society: Annual meeting at Newport on December 2. Officers elected: *President*, Dr. Ira H. Erwin; *Vice-President*, Dr. L. T. Slayden; *Secretary-Treasurer*, Dr. H. O. Walker.

**Obituary Notes.**—Lieutenant-Commander William M. Wheeler, Surgeon, United States Navy, a graduate of the University of Virginia, Department of Medicine, Charleston, in 1895, and a member of the American Medical Association, and the Medical Society of the District of Columbia, died at the Naval Hospital, Washington, after a long illness, on December 14, aged 39 years.

Dr. Thomas J. McCloskey, formerly of Beloit, Wis., a graduate of the St. Louis College of Physicians and Surgeons, in 1899, and a member of the State Medical Society of Wisconsin and the Lafayette County Medical Society, died at the home of his sister in Dubuque, Ia., after a long illness, on November 28, aged 53 years.

Dr. Amos Henry Elliott of Brooklyn, N. Y., a graduate of the New York Homeopathic Medical College and Hospital in 1888, and a member of the American Institute of Homeopathy and the New York State Homeopathic Medical Society, died suddenly at his home on December 12, aged 73 years.

Dr. John W. Staples of Franklin, N. H., a graduate of the University of Vermont, College of Medicine, Burlington, in 1880, and a member of the American Medical Association, the New Hampshire Medical Society, of which he was at one time president, and the Merrimac County Medical Society, died suddenly at his home on December 11, aged 58 years.

Dr. Arthur Fisher of Montreal, Can., Licentiate of the Royal College of Surgeons, Edinburgh, in 1880, died at his home on December 3, aged 67 years.

Dr. Rockwood Sager of Rockford, Ill., a graduate of the Rush Medical College, Chicago, in 1879, and a member of the Illinois State and Winnebago County Medical Societies, died at his home recently, after a short illness.

Dr. Lee O. Rogers of Newton, Ia., died suddenly at his home on December 4, aged 69 years.

Dr. Thomas Marshall Huntington of Amesbury, Mass., a graduate of the Bellevue Hospital Medical College, New York, in 1883, was struck and instantly killed by a freight train at the Newburyport station of the Boston & Maine Railroad, on December 9, in the 54th year of his age.

Dr. Thomas E. Parke died at East Downingtown, Pa., on December 13, at the age of 62 years. He was graduated from the medical department of the University of Pennsylvania in the class of 1871. He was for many years president of the Dime Savings Bank of Chester County and a director in the Chester County Trust Co., and the Downingtown National Bank. He was for five consecutive terms burgess of Downington.

## Obituary.

### GEORGE HENRY TORNEY, M.D.,

SURGEON-GENERAL, UNITED STATES ARMY.

Surgeon-General George Henry Torney died at his home in Washington, after a short illness, from bronchopneumonia, on December 27. Dr. Torney was born in Baltimore in 1850 and was graduated from the University of Virginia, Department of Medicine, Charlottesville, in 1870. His first service was in the navy, to which he was appointed in 1871. Resigning from the navy in 1875, he was immediately reappointed in the army as assistant surgeon, and was promoted rapidly until he reached the rank of Major and Surgeon in 1895, Lieutenant-Colonel Deputy Surgeon-General in 1903, Colonel in command of the Medical Corps in 1908, and Surgeon-General of the Army in January, 1909. During his service he did duty both in Cuba and in the Philippines. He was a member of the American Medical Association, the Medical Society of the District of Columbia, and the Association of Military Surgeons of the United States, and chairman of the War Relief Committee of the American Red Cross.

### ALFRED E. M. PURDY, M.D.,

NEW YORK.

Dr. Alfred E. M. Purdy died at his home in this city on Christmas Day, after a short illness, aged 75 years. Dr. Purdy was graduated from the College of Physicians and Surgeons, New York, in 1861, and directly thereafter was appointed an assistant surgeon in the United States Army, serving on the staff at Fort Schuyler. In 1870 he was appointed a surgeon on the New York police force, and later became chief surgeon, in which position he remained until 1880. He was for many years editor of the "Medical Register," now the "Medical Directory of New York, New Jersey and Connecticut," and was one of the organizers and at the time of his death consulting physican of the Methodist Episcopal Hospital and Home, Brooklyn. He was also a life member of the New York Pathological Society, and a member of the New York Academy of Medicine, and the New York State and County Medical Societies.

## Correspondence.

### LUNDVALL'S REMEDY FOR DEMENTIA PRÆCOX.

To the Editor of the Medical Record:

Sir:—The prognosis in dementia præcox has been and is almost uniformly unfavorable. In the State of Massachusetts only one out of each 1,500 admitted to the State hospitals with this diagnosis during seven years recovered. The systematic writers give a rather better prognosis, allowing that anywhere from one to eight in each hundred recover with some defect. The cause of this insanity of adolescents is absolutely unknown. The pathological findings are trifling and for the most part neglected. The duration of the disease is long, averaging more than ten years. These unhappy, often starving, creatures of our neglect make up more than 60 per cent. of the asylum population.

Thirty years ago Savage noticed that many mute and inactive cases of dementia præcox became awake to their condition, took an interest in their surroundings, and voluntarily talked with their attendants during the progress of a febrile disease such as typhoid fever or erysipelas, and that some of these patients went on to complete psychic and physical recovery. Boody estimated that one-fourth of the insane patients in two epidemics of typhoid at the Asylum for the Insane at Independance, Iowa, made temporary mental improvement and at least two remarkable cases recovered so completely that they returned to their professions, one to law and one to engineering. Wagner and Lehmann (1887) gave their similar experiences and reversed the existing literature, and since that time scarcely a year has passed without some valuable contribution on the same subject, recounting the experience of the author in confirmation of the thesis, that *the febrile diseases often exert a temporary or even a permanent betterment on the psychic and physical condition of dementia præcox patients.*

One of the earliest studies of the blood of the insane was the work of W. L. Lindsay (1854), but little was accomplished until the strong presentation of L. Bruce in his popular "Studies in Clinical Psychiatry" (1906) in directing attention to the leucocytosis and polycythemia that marks the remissions and exacerbations of dementia præcox. He noticed that hyperleucocytosis was present in improvement and leucopenia in deterioration. Dide, Chénais, Donath, Lepine, and Popoff in France, Galdi, Pighini, Sandri, and Paoli in Italy, Ellermann and Erlandssen, Lindhard and Lundvall in Sweden, continued these researches and developed as clear a blood picture characteristic of dementia præcox as the long recognized blood picture in typhoid fever is of that disease. This finding is now to be known as "the blood crisis" of Lundvall (see *Hygiea*, 1907).

Only during the last ten years has the pathognomonic pupillary symptom complex of dementia præcox attained recognition. This phenomenon is often referred to as "Westphal's pupillary stare." but Weiter, Huber, Sioli, and Oswald Brumke have extended Westphal's observation and shown that not alone in advanced cases of catatonia but also in early cases of dementia præcox there is in more than six-tenths of the cases a characteristic pupillary complex in which the pupils are widely dilated and the normal pupillary unrest and the normal reaction to touch are absent while all the time light reflex remains present and normal. The pupils assume a drop-shaped or slit-like form under myosis. One pupil is sometimes alone affected. The cyanosis and dilatation of blood-vessels present a strong argument for the toxic nature of dementia præcox.

Early in 1912 the epoch-making little book of Emil Abderhalden appeared with his new method of organic synthesis. It is best known to physicians by its application in the diagnosis of pregnancy. This remarkable method has, however, been applied in the diagnosis of dementia præcox and epilepsy. In this short time Fauser and Wegener and several other investigators report a most uniform differential reaction between dementia præcox and manic depressive insanity.

With these growing indications, almost demonstrations of the physical and toxic etiology of dementia præcox, it is no wonder that efforts have been repeatedly made to bring about artificially the hyperleucocytosis which attends the improvement of these patients in their attacks of typhoid and other febrile diseases. The nucleates of sodium have been used by Donath, Fischer, Ittan, and Lundvall. On nine patients Ittan* used subcutaneous injections at intervals of ten days or less of 50 c.c. of a 1 per cent. solution of the nucleate of sodium; chills, fever, and leucocytosis followed, and in two cases betterment. One patient, mute for twelve years, volunteered conversation and played chess. Lundvall† after giving a full account of his studies of the blood and a careful outline of his technique proposes a more concentrated solution of the nucleates with sodium cinnamate and arsenic. The plates consist of charts showing the blood reaction to the injections which were given after protracted study of the blood of the same patient before treatment began. The differential white count is made on a study of thousands. He recommends the injection subcutaneously of 2 to 15 c.c. of the following sterilized solution at intervals, corresponding to the duration of the reaction, of four to twenty days: Sodium nucleinate, 10.000; arsenous acid, 0.005; sodium cinnamate, 1.000; distilled water, 40.000.

While there is sometimes pain at the point of this injection which is much relieved by hot applications, no abscesses were produced in several hundred cases injected by Lundvall. A few hours after the injection there is a chill more or less pronounced, and the temperature rises two or more degrees. The leucocytin increases correspondingly, but sometimes the leucocytes increase without high temperature or the hyperleucocytosis remains after the temperature subsides. None of the patients were made worse by the treatment.

In his thesis Lundvall reports eighteen cases in considerable detail. Of these eight cases of dementia præcox recovered, some of them rapidly, some slowly, but all quite completely; five or six made remarkable improvement. Of the remaining five cases only three, and these of doubtful diagnosis, showed no improvement.

Lundvall's patients were not selected from the very early or favorable cases, but were those in whom he had been able to follow out a long series of observations on the changing blood picture. He

†Lundvall, Halvar: Uber Blutseränderungen bei Dementia præcox nebst einen Versuche einer Art spec. Therapie. *Tidsskrift for Nordisk Retsmedicin og Psykiatri*, Vol. 10, 1912, pp. 227-306. 30 plates and figures.

lays much stress upon the technique of the examinations, and presents twenty-nine charts illustrating the findings in these patients covering long periods of observation. It is too much to believe that we have in Lundvall's remedy a method of curing dementia præcox, but his modest report certainly commands us to investigate in our crowded institutions a method which has proved successful in 40 per cent. of a most unpromising series of confirmed patients.

BAYARD HOLMES, M.D.

108 N. STATE STREET, CHICAGO.

## OUR LONDON LETTER.

(From Our Regular Correspondent.)

TREATMENT OF GUNSHOT WOUNDS—NON-CANCEROUS TUMORS OF THE STOMACH—FISHBONE IN STENO'S DUCT—BISMUTH MEALS—NOTIFICATION OF DISEASE—LISTER MEMORIAL—OBITUARY.

LONDON, December 12, 1913.

THE Bradshaw lecture for this year was duly delivered on the 5th inst. at the Royal College of Surgeons. Mr. G. H. Makins, vice-president, was the lecturer and he took for his subject "Gunshot Wounds." He was supported by many fellows and members, a good proportion of them being connected with the Red Cross Society and the Royal Army Medical Corps. Mr. Makins devoted the lecture to gunshot wounds of small caliber—bullets in fact—respecting which he remarked that a single battle offered more experience and that of a more various kind than years of laboratory or experimental work. So large was the subject that he would restrict himself mainly to a consideration of the wounds of one set of structures—the arteries. The last decade had furnished us with some remarkable evidence of the amenability of the wounded vessel to methods of treatment other than obliteration by application of a ligature. Changes have taken place in the form of bullets which have brought about other modifications. The most striking danger during the last decade was perhaps the introduction of the pointed bullet by some powers. This alteration in the outline of the bullet is designed to overcome the resistance offered by the air to its progress and so obtain a greater velocity in its flight as well as more striking power on impact. But these advantages are obtained at the expense of the consequent shifting backwards of the center of gravity of the bullet and this in turn increases the difficulty of maintaining its flight parallel to its long axis. Some experimental work has seemed to show that this last character would result in a more serious wounding capacity, since slight inaccuracies of impact will suffice to cause a sudden somersault of the bullet and consequently a greatly increased surface of resistance to its entry into the body with a widening of the area of tissue destruction. The lecturer mentioned a peculiarity of practical importance that had been observed as to these pointed bullets when retained in the tissues. That was a tendency to travel such as needles have long been known to display. The new bullet possessing a sharp point has greater penetrating power than its predecessors and makes narrower, cleaner perforations. The wound made by it differs from that caused by the older missile much as does one caused by a sharp instrument differes from that produced by a blunt one.

At the Royal Society of Medicine on the 25th ult. two cases of tumors of the stomach, non-cancerous, were described and specimens shown by Drs. Gossage and Braxton Hicks, who considered one fibromyoma and the other fibrosarcoma. They were admitted into hospital suffering from hematemesis, rather an uncommon cause of death in gastric tumor of this class. They were too ill for surgical measures to be undertaken.

Mr. Newton Pitt showed a case of recurrent distention of the parotid gland due to calcification round a fishbone retained for over a year in Steno's duct. The patient was a man of fifty-eight who thought he felt it stick in his throat, but though the symptoms abated some discomfort persisted and the right parotid had swollen up several times. Sir A. Lane had suggested there might be a calculus in the duct. An *x*-ray picture gave a shadow in the line of the duct behind the edge of the masseter and slightly bifurcated in front. Exploration from inside being without result the gland was cut down upon. No calculus was found but the duct seemed thickened and atheromatous. A tube was passed down the duct and out of the month and the wound closed. After healing the swelling recurred from time to time, the tube came out, and on the fourteenth day the wound broke down and on the eighteenth an elongated shell of bone was extruded, the anterior end of which was bifurcated and so prevented movement except upwards. Dr. Pitt observed that foreign bodies in the salivary ducts were rather rare. He only found records of twenty-seven in Wharton's duct, nineteen in Steno's, and two in the sublingual. Straw or blades of grass were found fourteen times, fishbones seven, bristles six, ears of corn five, feathers three, fruit seeds and splinters were removed twice, while a piece of toothpick, another of chestnut, a hair, and a shot had each furnished one case.

At the Section of Electrotherapeutics Dr. R. Morton opened a discussion on the technique and standardization of bismuth meals, with the object of getting comparable results. He had found that meals were being given by different radiologists of very various description—one of 5 oz. containing 2 oz. of bismuth, another of 20 oz. with 1½ bismuth—all agreed that it should be as palatable as possible. Those using 20 oz. found some difficulty in getting it all taken. Quite one-half those asked were using a 10 oz. meal with 1 to 4 of bismuth or barium, the average being 2 oz. A minority preferred barium as requiring so much less. A light form of bismuth carbonate which remained suspended in water for some time had been put on the market and its shadow seemed as dense as the heavy form. It was said that oxychloride did not neutralize the gastric juice as carbonate did. Two-thirds of his informants spoke of bread and milk as a medium of suspension, others porridge, blanc mange, etc. In France gum solutions were used and in America buttermilk. His idea of the meal was: 2 oz. bread crumb cut small, on which was poured 8 oz. of boiled milk, into which had been stirred 2 oz. bismuth carb. or oxychlor. (or 3 oz. of barium sulph.). Sugar to taste. He would order an aperient thirty-six hours before, and an enema the same morning of the examination, the bismuth meal taking the place of the usual breakfast. No other meal for four hours after the bismuth. His correspondents had examined 2, 4, 6, 12, 24 and 36 hours after it. He proposed the appointment of a committee on which Dr. Hertz should be asked to serve on account of his work on the subject, and this was agreed to. Dr. Morton to be

convener and Drs. Scott, Barclay, and Jordan to act with him and Dr. Hertz, with power to add others. In a note sent to the secretary, Dr. Hertz warned against subnitrate of bismuth, which had caused poisoning. Even carbonate was a depressant of peristalsis. Oxychloride was the only bismuth salt inert in the stomach. Barium sulphate was quite as useful for *x*-ray work. The smallest quantity which would answer should be used as distortion was caused by the heavy salt. He used 2 oz. of barium added to a 4 oz. meal and discontinued aperients at least forty-eight hours before the first examination. Each morning an effort at defecation should be made and the ordinary diet continued so that the examination might be made under the ordinary condition of the canal.

The Harveian Society had a discussion on the 27th ult. respecting the proposed registration and notification of venereal diseases. Dr. R. Dudfield was in favor of the proposal, but he was alone, and seven other speakers were opposed to it. One of them drew attention to the fact that no indication had been held out that medical men would be protected against the consequences of breach of confidence or errors of diagnosis.

To the Lister Memorial it is proposed to give a threefold form—a simple medallion bearing a sculptured portrait to be placed in Westminster Abbey, a larger monument in some public position in London, where he lived and worked in the later years of his life, and if the amount subscribed suffice, the foundation of an international fund to make grants in aid of researches bearing on surgery and awards in recognition of important contributions to surgical science.

Dr. Inspector-General T. J. Preston has died at the age of 66. He entered the navy in 1873 and rose to be fleet surgeon in 1894, having served at Alexandria in 1882, and afterward in the Egyptian War to the surrender of the Aboukir and Saretta forts. He was awarded the Medal and Clasp and the Khedive's Star, and in 1888 the Sir Gilberg-Blane Gold Meal. He retired in 1902.

Dr. Richard Macartney, Coroner for the Forest of Dean since 1907, died on the 6th inst. He was born in Ceylon in 1861.

5. Dr. Fitz's Service to Medical Education. Charles W. Eliot.
6. A Symposium on the Reportability and Control of Venereal Diseases. S. L. Strong.

**1. The Late Dr. Reginald H. Fitz.**—W. W. Keen reviews the important contributions made to surgery by the late Dr. Fitz. In 1886 he first named the disease now so familiar under the name of appendicitis, established its origin from the appendix, elaborated its diagnosis and indicated on broad lines its proper treatment. In 1889 he classified and clarified the knowledge of pancreatitis, a disease at that time emerging from obscurity into concrete form as a surgical entity. He reviewed the reciprocal relations of the physician and the surgeon, encouraged their hearty cooperation and laid a restraining hand on the sometimes too radical tendencies of the surgeon. By his personal relations and influence as a consultant and teacher, he rendered signal service both to medicine and to surgery by advocating surgical treatment to his laggard brother physicians and by pointing out the safest path to the surgeons.

**6. The Control of Venereal Diseases.**—S. L. Strong made a canvass of fifty physicians in different parts of the country, requesting their opinion as to the advisability of reporting venereal diseases. He concludes from this inquiry that as to belief in the reportability and control of venereal diseases by boards of health a majority of physicians believe in it at the present time. On the matter of practical adaptation and enforcement the profession is about equally divided, the prevailing view being that more efficient means of treating these diseases in hospitals must be provided before such a move can be taken. Venereal diseases cannot probably be controlled to the same degree as smallpox, scarlet fever, diphtheria, etc., for some time to come. The desirability of gathering more accurate statistics regarding the efficiency of the treatment of venereal diseases is widely recognized. This should be done by societies already existing or by the formation of new organizations with this special object.

8. Atypical Infantile Paralysis. F. L. Wachenheim.

**1. Diabetes.**—R. Lépine refers to the practical importance of decreased glycolysis as an essential factor in the disturbed metabolism that results in diabetes. In certain forms of diabetes there is an exaggerated formation of sugar at the expense of the amino-acids. The view of the decrease of glycolysis in diabetes affords an important therapeutic indication—that of increasing glycolytic activity. Diet is not the sole means of accomplishing this. The diabetic patient must be thoroughly examined, every abnormality of nutrition sought out, and an attempt should be made to restore the nutritive state to normal. Diet is essential in the treatment of diabetes; but generally there is something to be ordered besides. To throw aside all medicinal measures is a mistake; not that there exists at this time any specific for the disease, but because this or that drug may correspond to some indication in a given individual. For example, the author has observed a patient who could not do without quinine, though he was not malarial. Another patient may do well on opium, etc. The utility of the alkalies is generally recognized; physical agencies should not be entirely overlooked. It is well known that glycosuria is increased by a low surrounding temperature, and that a moderate degree of heat decreases it. Climatotherapy may be resorted to in some cases with advantage.

**2. Orbital Abscess from Infection Through the Ethmoid.**—J. O. Roe notes that the intimate and important relations existing between the ethmoid labyrinth and the orbital cavity are well illustrated in the cases of orbital abscess resulting from an acute extension of an ethmoid infection. He reports two of these cases. This intimate relation is also shown in the frequent disturbances of vision that result from nerve irritation, reflected from the nose to the retina and to the ocular muscles—this irritation being caused by intranasal pressure, the result of various diseased conditions of

the turbinate bodies and of the accessory sinuses. Onodi has clearly shown how this takes place through the anatomical connection of the two regions. Notwithstanding the fact that many cases of visual defects and disturbances from nasal and accessory sinus diseases are reported by different observers, the subject is not given the attention it should receive. Many chronic visual defects and also many chronic headaches that are attributed to these visual defects go unrelieved because the fundamental cause of the disturbance in a large proportion of cases remains unrecognized. The author's two cases of ethmoid disease in the acute form, illustrating this intimate association of the ethmoid sinuses with the orbital cavity, are of special interest, the first one particularly so because it illustrates not only the readiness with which ethmoid diseases may extend to the orbit, but also the ease with which the orbital cavity can be reached and abscesses of this region opened by the nasal route.

4. **Bacteriology of Pyorrhea Alveolaris.**—C. P. Brown has isolated a large number of organisms in a series of cases of pyorrhea alveolaris, but is unable to attribute to any one germ an etiological rôle in this condition. Plain or serum agar, plain or serum bouillon, or Loeffler's blood serum mixture is not the best culture medium for studying diseases of the mouth and of the respiratory passages. Blood agar is the best culture medium for work of this kind because the hemophilic bacteria grow only upon this medium; in addition to this a number of types of streptococci can be differentiated at once by the appearance of the colonies. A vaccine for the treatment of pyorrhea should contain all the organisms isolated in a given case. Before one may draw final conclusions on this subject a study of the possible association and rôle of anaerobic bacteria is necessary.

7. **Pellagra in Maine.**—E. W. Gehring reports three cases of this condition which he has observed in Oxford County, Maine, during the past spring and summer. These cases, together with others recently reported, fail to establish the etiology of the disease, but they confirm the belief that pellagra is not a disease peculiar to tropical regions. The author's patients had never been out of the State and had lived continuously in Oxford County, where they had been born. All had gastrointestinal symptoms and typical skin lesions, but only two presented any mental abnormality. In two of the patients mental symptoms preceded those of the gastrointestinal tract and skin, whereas in the third, although the skin looked as if painted with iodine, and diarrhea was a distressing symptom, the mind was not affected.

2. **Entericoid Fever.**—D. Riesman states that the term "typhoid fever" as commonly used by physicians includes more than one disease. Only that disease in which the characteristic serological and cultural tests for the typhoid bacillus are obtained should be called typhoid fever. To the others, which clinically resemble typhoid very closely, the terms "entericoid fever" may be applied. The entericoid fevers are due to different strains of organisms of the paratyphoid group and to others morphologically similar (Gärtner's *Bacillus enteritidis*, etc.). The source of infection is chiefly food derived from unhealthy animals. Food (including drink) may become contaminated through contact with diseased meat, through rodents and birds, or through the discharges of carriers, etc. So-called second attacks of typhoid fever are probably paratyphoid fever. In all cases of typhoid-like character careful search should be made for the source of infection, and blood-cultures and other tests should be made for the determination of the infecting agents. By combined clinical and laboratory investigations it should eventually be possible to distinguish, according to their specific etiology, the various entericoid diseases now groupd together.

3. **Treatment of Hemoptysis in Pulmonary Tuberculosis.**—N. B. Burns describes the following method in the treatment of hemoptysis: The treatment consists mainly of purgation. The patient who begins to expectorate blood is made to lie down and keep perfectly quiet, and one one-hundredth of a grain of nitroglycerine is injected hypodermically as soon as possible and perfect quiet is enjoined. A curved basin is placed next his face so that the patient can expectorate without moving, and tight-fitting garments are loosened, but complete undressing is not usually advisable at once. The patient should be encouraged and told that his condition is not likely to be fatal and should be advised against unnecessary coughing or movement. Except in case of extreme asthenia or gastrointestinal irritation, a dose of one or two ounces of magnesium sulphate is given from fifteen to thirty minutes after the beginning of the hemorrhage. The good effects are shown as soon as the purgative action begins. In about eight out of ten cases hemorrhage does not occur. The reasons for adopting this method were, the observation that severe constipation is the rule in patients having hemorrhage, and the sluggish bowel condition seems to be a causative factor. Another reason was the high blood-pressure in cases of hemoptysis. The after-treatment consists in keeping the patient at rest, giving non-irritating liquid food, and preventing constipation. The patient is kept flat on his back without a pillow for at least twelve hours. Ice to the chest is continued only for about three hours, but can be replaced if needed, as too long-continued use of it may do harm. One grain of sodium nitrate may be given every three hours with the idea of reducing the blood-pressure. If the cough is very severe, codeine by the mouth in small doses is preferred to morphine or heroine. For nourishment the patient should receive four ounces of cold milk with perhaps a scant teaspoonful of lime-water every three hours. If the sputum becomes clear in eighteen hours, more solid nourishment in the form of dropped eggs may be given. The bed-pan is continued for three or four days, but the patient is not allowed to be up for any length of time for at least seven days after the sputum becomes clear. The advantages of this method of treatment are shown in the absence of fever and

slight loss of weight as compared with the efforts of the morphine and atropine treatment.

**9. The Infantile Type of Kidney in Renal Diagnosis.**—J. T. Geraghty and H. W. Plaggemeyer state that when disease is present in the larger, hypertrophied kidney, the total function, as estimated by phenolsulphonephthalein, is decreased, and the function of the diseased kidney is usually greater than the function of the supposedly healthy kidney. The function of the infantile kidney shows marked decrease, although the urea percentage and general character of the urine are normal, while the amount of urine secreted is relatively small. Pyelography is of doubtful value, since the size of the kidney pelvis is usually not a reliable index of the size of the kidney. In persons not too stout it may be possible to secure Röntgen-ray shadows, showing the presence of a diminutive kidney. The fact is emphasized that kidneys of the infantile type are a menace to the surgeon if the opposite kidney is the seat of disease. The character of the urine may be normal in appearance and the urea concentration or percentage may be high. The recognition of this anomaly may be extremely difficult, and its presence can be suspected only when function estimations are carried out.

**1. Some Errors in the Diagnosis of Nervous Disease.**—S. A. Kinnier-Wilson notes that as a rule a case of organic hemiplegia is readily recognized, particularly if the onset is sudden and is associated with unconsciousness. But hysterical hemiplegia is not rare. The absence of the epigastric and abdominal reflexes on the affected side, and the presence of an extensor movement of the great toe on stimulating the sole of the foot, are signs that postulate organic disease. There may, however, be a flexor response, and in hysteria the abdominal reflex may be diminished, especially if there be any degree of cutaneous anesthesia. Ankle clonus may help one to reach a definite conclusion. In organic cases it is rhythmical and the excursions are equal; in functional disease it is often highly irregular in time and extent, and the patient seems sometimes to be unconsciously endeavoring to start or to continue the phenomenon by pressing downward with the forepart of the foot. A consideration of the nature of the paresis or paralysis may prevent an error in diagnosis. The hysterical patient very often shows the condition of defective inhibition of the antagonists. A common mistake is the failure to separate from the scrap-heap known as neurasthenia the class of cases variously known as cardiac neurasthenia, pseudo-angina pectoris, etc., but best described by the appellation "vasovagal attacks." These attacks are allied both to epilepsy and to migraine, and are due to instability of the vagus nucleus in the medulla and the vasomotor centre in juxtaposition. As a result the patient complains of attacks of difficulty in breathing, a suffocating feeling in the throat, palpitation, hot flushes, cold waves, perspiration, shivering, nausea, and an epigastric sensation, and often, also, an indescribably distressing sensation of trouble, of fear, even of imminent death.

**3. Jackson's Pericolic Membrane.**—J. Morley concludes from his observations that Jackson's pericolic membrance is of congenital origin and is noninflammatory. It occurs in association with abnormal mobility of the proximal colon, due to a failure of fusion of the ascending mesocolon with the posterior parietal peritoneum. The great omentum, from which Jackson's membrance is derived, is the most primitive agent in fixing the proximal colon to the parietes in the right loin. In cases of mobile proximal colon Jackson's membrane may be the principal means of fixing the colon. Unless it causes kinking of the colon a pericolic membrane is therefore rather useful than harmful, and should not be divided. The symptoms and pathological conditions found in association with Jackson's membrane (apart from mechanical obstruction due to the membrance) are primarily due to stasis in the abnormally mobile proximal colon, which is ill-adapted to the upright posture. Surgical treatment should be directed to securing the normal position and fixation of the proximal colon by the operation of colopexy.

**5. Myocardial Lesions from Streptococcus Viridans.**—E. C. Rosenow and C. Coombs present an account of the myocardial lesions found in rabbits inoculated with the streptococci isolated by Rosenow from cases of chronic ulcerative endocarditis. These organisms corresponded to *Streptococcus viridans*, but owing to the fact that numerous strains have been converted into pneumococci they have been designated as modified pneumococci. The affinity for the heart valves of rabbits of the strains of these cases as isolated has been shown to be striking. The experimental endocarditis has been proven to be embolic in origin. The vegetations here, as in man, tend to become very large, often obstructing the valve orifice. Rosenow has recently found that while the affinity for the endocardium of the streptococcus from rheumatism is as marked as that of *Streptococcus viridans*, the mode of origin also being embolic, the type of lesions produced is very different; the vegetations remain subendothelial and tend to heal, producing small nodular scars similar to the chronic nodular endocarditis described by pathologists as characteristic of rheumatic endocarditis in man.

## Berliner klinische Wochenschrift.

*December* 1 *and* 8, 1913.

**Rheumatism and Tuberculosis.**—Menzer makes the following points in his paper on this subject. The sole cause of acute, subacute, and chronic articular rheumatism is a bacterial infection of the upper air passages. This may be an acute streptococcus angina or an exacerbation of a latent infection. These latent infections may be seated in the nose and nasal sinuses, the ear, tonsils, bronchial glands, etc., and lead to a weakening of the organism expressed as anemia, headache, tendency to perspire, palpitation of the heart, frequent anginas and catarrhs in the head. In these latent foci, we find localized the ordinary exciters of catarrh (strepto- and pneumococci) and not infrequently tubercle bacilli. From these latent foci there may appear as a result of exposure or other constitutional injury, a general infection, which leads to metastases to the joints, heart and serosæ, etc. According as the constitution of the individual patient develops we see different expressions of disease. The powerful man who reacts the more actively is seized with an acute attack of articular rheumatism; while the weak, anemic subjects develop a subacute affection which lies between the acute and chronic forms. It is in just this last named type that we find tubercle bacilli in association with the catarrh exciters, first of all in obstinate, chronic inflammatory processes in the joints and other organs. But

in connection with acute articular rheumatism we find associated a not inconsiderable number of cases of latent tuberculosis. Every mode of treatment of the various forms of articular rheumatism must start with the conception that the joint and other symptoms are only the expression of a central latent infection and that nothing will be gained by treating the peripheral joint symptoms. Salicylic acid and other like remedies should therefore be rejected and immunizing or curative sera used in their stead, along with vaccines.

**Erysipelas vs. Nephritis.**—Glaser discusses the possibility of the cure of a severe nephritis by an intercurrent erysipelas. In 1675 Hoffmann mentioned the "salutary erysipelas" which favorably influenced lupus, syphilis, and rheumatism. In modern times sarcoma has undergone resolution after intercurrent erysipelas (not a word of mention of Coley and his serum). Finally, certain severe cases of psychoses are said to have yielded to the same remedy. These results cannot be duplicated in animal experiment. The author in seeing the sequence of nephritis cured by erysipelas, had predecessors in Langballe (complete cure) and Nyrop (improvement). Eichhorst has seen a favorable influence exerted under these circumstances. To sum up the author's case: In a boy of 12, a subacute nephritis setting in with marked edema, ascites and hydrothorax, underwent permanent involution after an attack of erysipelas over the buttocks and thighs. As regards a speculative origin we can only fall back on a suddenly exerted antitoxic action, or a powerful derivative action of the renal blood toward the skin.

**Camphor as an Antipyretic in Pulmonary Tuberculosis.**—Weihrauch states that we have in camphor when used subcutaneously or percutaneously an antipyretic for pulmonary consumption which will lower the temperature 20 per cent. We cannot decide with certainty how this depression is effected; it probably results from an inhibitory action upon the germ exciters of the disease, and perhaps also from a diminution of the catarrhal state of the affected mucosæ. Camphor is entirely harmless to the consumptive.

**Mouse Favus in Mankind.**—Fischer mentions the slight degree of interest in this affection cherished by experts. Even Sabouraud regards it as something which is only theoretically possible. However, what is rare under certain states may be of epidemic incidence in others. Quincke discovered the exciter of mouse favus in 1886, separating it from the Achorior Schoenleinii. After years of debate it became conceded that Quincke's fungus might be pathogenie to man—in fact that a number of kinds of fungus might be able to form scutula. We now know half a dozen or more species of favus. One kind while regularly pathogenie to certain animals, could occasionally domicile itself on another. Scutula formation is no longer the sole manifestation of a favus, for now and then they cause the same lesions as the trichophytinæ. We know now that the mouse favus can not only form scutula on man, but also the efflorescence of trichophytinæ. In a small epidemic, mouse favus appeared to extend to children, cats, and a group of women—twelve individuals all told. The polymorphism noted is doubtless due to special strains of fungus, not to differences in those infected.

**Importance of Lime Salts for the Therapy of Internal Affections.**—Kayser sums up his general review of this subject as follows: Calcium salts act upon the blood and blood vessels by tightening the unduly permeable vascular wall thus promoting coagulation and stripping exudation. They influence the excitability of the nervous system by depressing the latter, especially the vegetative and autonomous, and are therefore indicated in internal medicine especially tetany, epilepsy, hay fever, and asthma bronchiale, in all of which they are used with success. In disturbances of the calcium metabolism, as in rachitis, osteomalacia and Grave's disease, lime salts are also of use. Through the ability of increasing the phagocytotic power of the blood, lime salts appear to come into question for the therapy of infectious diseases like pneumonia and tuberculosis. Lime also cures oxalic acid poisoning. The salts may be given per os, subcutaneously, by the rectum, and intravenously. Hence it is essential to exhibit the remedy in large doses, and for a period of one or two weeks.

**Fecal Vomiting in Gastric Crises.**—Oczesalski refers to certain unusual conditions under which fecal vomiting occurs; but thus far he has found no mention of such an event in the gastric crisis of tabes. After describing in full one of his own cases. Before attempting to explain the case we have no proof that a gastroenteric fistula had not formed at some time, this hypothesis always giving a simple explanation of fecal vomiting. The only other solution is that of a purely nervous mechanism which caused antiperistalsis at the time of the crisis. A gastro colic fistula was excluded by the fluid character of the vomitus. The author found the gastroenteric fistula theory satisfactory to account for all the symptoms.

**Severe Anemia with Aphasia and Hemianopsia.**—Knoch discussed the association of anemia—not necessarily severe—with focal cerebral lesions. This association is a very rare one. It is most often seen in pernicious anemia, in which we see disturbances of motility, sensation, and special sense. The mechanism is doubtless a circumscribed thrombosis due to excessive slowing of the blood stream or some other vascular disturbance. The author regards these lesions as permanent.

### Münchener medizinische Wochenschrift.

*November 18 and 25, 1913.*

**Practical Identity of Radium and Röntgen Rays.**—Pagenstecher mentions the enormous prices of radium and mesothorium and alludes to the need of some cheaper substitute. Radium is composed of three kinds of rays, of which the *a*-rays have the greatest penetrative powers. The *b*-rays closely resemble the cathode rays. The *x*-rays originate from the *b*-rays, as the *x*-rays from the cathode rays. The author shows the likelihood that in the future the *x*-rays may be endowed with the penetrative properties of radium and mesothorium. To use superhardened *x*-rays is not to secure this conquest, for rays may be too powerfully penerative as well as too feebly. The future tubes should be hard, carry a high tension, and have increased lead filtration.

**Unusual Case of Rumination in Man.**—This is related by von Gulat-Wellenburg: In October of this year a man exhibited himself in Münich. His art was to swallow frogs and fishes and bring them forth alive. This he did thirty times daily. Before this feat he drank water by the quart; then swallowed in succession some twenty frogs or goldfish; and while these were within him conversed and moved about. By a silent effort he then allowed the creatures to escape separately; he afterward expelled the water through a tube, pressing the last of it with his hands. The man was sixty-three years old, small, but well nourished. His demeanor is quiet and natural, in no wise hysterical. His palatal reflex, like all others tested, was normal. He exhibited the trick of rumination as a boy and began to regard it late in life as a possible source of income. There was evidence to show that his habit of rumination was familial. He was tested with *x*-rays by the author and others. The stomach was not distended, and even seemed smaller than normal; all the digestive organs and esophagus seemed intact. In order to trace the swallowed objects they were baryumized (a dead frog and two finger cots). The muscle tonus of

the stomach is excellent, while the chemistry is abnormal. The conclusion was reached that the stomach possessed an abnormal elasticity. Stomachs of this type have been used in several kinds of deception.

**Leukemia, Lymphoblastic and Myeloblastic.**—Herxheimer concludes his serial article as follows: Two forms of leukemia may occur in the same individual—lymphoblastic and myeloblastic. The former is usually a chronic, the latter an acute affection. In a case related the author states that the mediastinal tumor with its rapid evolution, the tumor-like change in the pancreas and the heart are to be referred to myeloblastic leukemia. The two forms might be placed in direct connection with each other for certain reasons, but the author chooses to regard them as quite distant, or in other words he is a dualist. During the past year he has treated three cases of myeloblastic leukemia. In one of these he mentions the great difficulty of diagnosis; it is necessary for myeloblasts to preponderate in the blood, to drive all other formed elements from the blood and even from leukemia growths, and finally to give the positive oxydase reaction.

**Are So-Called Diatheses Constitutional Anomalies?**—Pässler has already written of a special diathesis indicated by chronic tonsillitis, chronic infection of the nasal sinuses, and especially chronic conditions of the teeth, either caries or pyorrhea alveolaris. He feels that the reader will regard him as a lobbyist or "one sided" observer. He finds evidence that many classes of cases exist clinically. Thus one is characterized by acute exacerbation of chronic focal disease. There is no evidence of infection. We note the occurrence of relapsing anginas, pharyngitides, bronchitides, etc. In a second class we see tendencies to high and low temperatures, chills and sweating, prostration, exhaustibility, headache, etc. In a third a tendency to hyperplasia of lymph-nodes, especially of the pharyngeal rings and nearby lymph-nodes. Next in order comes a remotely exerted action on the most varied organs and systems bearing the stamp of direct and indirect infection. These are constituted by rheumatic phenomena as affecting the motor apparatus. This class is very numerously represented. Akin to the above is the vascular expression, including the vasomotor apparatus, as manifested in part by the results of inflamed glands of internal secretion. Forms characterized by nervous phenomena are made up of restlessness, with tendency to be startled, irritability, inability to concentrate, and perhaps sleep disturbances. Pseudochorea may belong here. As expressed in the gastrointestinal tract, under such generic terms as dyspepsia and constipation, we find a variety of special conditions, such as mucomembranous enteritis. Another class has to do with the uropoietic apparatus in which a great number of conditions may be reckoned. There is hardly any need to pursue this subject further, as the various affections make up almost the entire pathology of the body. This the author appears to admit in the interest of chronic diseases. As he implies or states, there is but a single diathesis as far as chronic conditions go which practically comprises all chronic disease.

**Diet and Dietetic Treatment from the Vitamin Viewpoint.**—C. Funk of the Cancer Research Institute, London, writes entertainingly on this subject, for there has been much discusssion as to vitaminous foods and their proper administration. There is a loss of vitamin when we remove the peripheral layers of various grains (rice, maize, wheat, rye); also when we overheat our food: from the washing out in cookery; and especially through drying. In improper preparation of food in general, we lose not only the vitamins, but also other nutrient constituents. The author compiles two tables of food: Those containing vitamin are breast milk, raw cow's milk, boiled milk (brief, single exposure), butter, cheese, yolk of egg, meat juice and broth, fresh potatoes and green vegetables, vegetable soup, fresh fruit, fruit juices, plain or cooked, lime juice, whole wheat bread, whole rye bread, red rice, lightly boiled meat, fresh beer yeast, yeast extract, and cod liver oil. Foods which contain little or no vitamin are sterilized milk and preserved milk, repeatedly boiled cow's milk, white of egg, dried fruit and vegetables, white bread, flour, rice, sago, dried and polished maize, Indian meal prepared from same, etc., etc. In regard to pellagra the author concludes that maize or Indian meal does not suffice as chief nourishment and should be consumed with vitaminiferous potatoes, fruit, vegetables, meat, etc. Whole Indian corn alone may be dependable as food.

**Protection from the Toxic Component of Hypnotics.**—Cimbal thinks he has found a formula which can "dope" or deaden the action of the leading hypnotics, notably veronal. He uses to offset the toxic effects of the latter antipyrin, phenacetin, codein, pantopon, ipecacuanha, etc. The last is especially recommended. When desire for suicide is present, along with veronal with a single synergist, a certain quantity of ipecacuanha root in powder is given.

## Deutsche medizinische Wochenschrift.

*November* 27, 1913.

**Development of Psychical Activity.**—Von Bechterew sums up his serial article as follows: Phenomena of neuropsychic activity are manifold and detach themselves from the entire circle of biological and somatic development; nevertheless the laws which dominate over these phenomena are the same as those which preside over the organism itself, the transformation of dead matter, and the development of the universe. In these generalizations we see the proof that psychology as science, and especially the psychology of the child, must be studied as all other natural sciences. This robs it perhaps of the stimulus of philosophical abstraction which should cover a broad and nebulous perspective; and therefore tends to make it a science which is just as exact as any other section of natural science; and on that account at least in the future, guarantees the best results; which will render possible in certain cases more accurate scientific prognoses which repose upon a fixed regularity of phenomena, and a definite reciprocity of causes and effects. When it is also determined that the development of the neuropsychic sphere upon the reproduction and alteration of the reflexes, rests upon the imitation of what is seen and heard; and at the same time the differentiation and the associative generalization or analysis and synthesis of the visible material can be brought together, though the education must begin in the first days of life and must above all represent a family education. Education must therefore endeavor to furnish the child with good material for imitation, both intellectual and emotional, in order to differentiate the esthetic and moral spheres. Care must be taken to secure a more or less synchronous and more ample synthesis of the intellectual, and likewise esthetic and moral synthesis, for the one and the other represent the basic condition of the development and completion of the human personality.

**A New Antidiphtheritic.**—Two articles appear on the same subject in this number, one by Freund, the other by Kausch. The more or less secret preparation has been known since 1898 and has been known under at least three separate names. Apparently it has been resurrected because of the criticism of serotherapy in the Berlin epidemic of 1911, criticism by no means warranted by the full data. The remedy is not intended to supplant serum of course, but to reinforce it. It is said to be a powerful bactericide and some of the references to it are in bacteriological periodicals. It is thought to be of special service in cases of bacteria carriers.

# Insurance Medicine.

## SUGGESTIONS TO MEDICAL EXAMINERS.

BY THE INSURANCE EDITOR.

### THE SIGNIFICANCE OF VALVULAR LESIONS IN LIFE INSURANCE.

THE statistics of deaths occurring directly or indirectly as a result of impaired valves of the heart are meager and of little practical value, so that in estimating the future danger liable to result from these lesions we are limited in a great degree to our clinical experience and knowledge of the structure and functions of the valves. Those who devote their time exclusively to the practice of medicine, viewing the subject, as they do, from a different point of view, are prone to state at times that the medical officers of life insurance companies overestimate the gravity of heart murmurs. A large part of the duty of the consulting physician is fulfilled when he makes a diagnosis, gives the patient good advice, and assures him, if the murmur is uncomplicated, that he will probably live as long as the next fellow if he follows the instructions and avoids indiscretions. The advice is often forgotten but the adviser has done his part and will not be open to future criticism in any event. The medical director is expected to foresee the liabilities in a general way for many years to come, even to the later years of the policies. His decisions are carefully recorded, not to be forgotten in a few years, and are of importance to the ultimate as well as the immediate interests of the policyholders.

It is popular among the medical profession at large to regard certain organic heart murmurs as of little clinical significance unless accompanied by signs of serious disease, and to base the prognosis chiefly upon whether evidence of cardiovascular disease, such as dyspnea, etc., is present or absent. This is all very well for the consideration of the present but it will not answer for the possibilities of the remote future. Patients with cardiac disease consult their physicians because they have some evidence of disease, but people apply for life insurance, as a rule, with the impression that they are healthy and sound. It is safe to say that the vast majority of applicants with valvular trouble have absolutely no subjective symptoms or indications of a lesion aside from the heart murmur. Many of them have even no appreciable hypertrophy, probably because the leaks are small. The medical examiner, therefore, will seldom be called upon to consider cases with advanced disease or complications.

The question arises, are applicants with simple heart murmurs insurable? It is well known that some persons with valvular lesions live to advanced age, but the medical officers of life insurance companies, treating these cases as a class, cannot agree with the belief that the condition may be lightly regarded, even when no signs of progression are present. It is not reasonable to suppose that 100,000 diseased hearts, with their delicate and complicated structure, will work on incessantly and constantly for a long period of years without a sufficiently large number of them coming to grief to make this group unprofitable to insure at the ordinary rates computed for payment by sound, unimpaired risks. It would be an injustice to those paying the ordinary rates to insure unsound individuals at the same cost. Nearly all of the 100,000 hearts may show no disposition to flag or falter to-day, but where is the clinician who can point out those individuals to the companies who will sooner or later succumb to excessive pressure brought on by hard work due to the inexorable demands for existence, by continued excitement or nervous strain, by immoderation in eating and drinking, or by the increased burden thrown upon them by intercurrent disease. Men in the business of selecting insurance risks make no pretensions to determine in advance the course which will be pursued in the great majority of individual cases of heart murmur. It is imperative, nevertheless, for due allowance to be made for all degrees of hazardous risks, and the only practical method for accomplishing this end with applicants who have heart lesions is to regard them as a class calling for rejection except where the company considering the proposition has perfected an arrangement for accepting substandard risks at advanced rates.

A moderately leaking valve is believed by some to act as a safety valve under excessive pressure. A murmur is sometimes produced in a sound heart by back pressure during or after unusually vigorous exercise or mental excitement and is, of course, of no consequence. The fact that a leaking valve may relieve excessive pressure to some degree in the event of future disease of other organs will hardly moderate the prevailing distrust of valvular diseases as a class.

A company who has adjusted certain rates to apply to substandard risks may safely accept most applicants presenting themselves with valvular defects if a number of years is reckoned off from the individual life to correspond with the natural period of degeneration, *i.e.*, the period in which the reserve powers of repair will become a diminished quantity. In addition to this, the merits of each case must be considered as to whether the heart may be expected to maintain its efficiency up to the period of degeneration, the conclusion depending largely on the particular valve or valves involved, the occupation, habits, financial condition and environment. The mortality will be higher than in the class of unimpaired lives but the extra risk will be covered by the raised rating. Even this method is impracticable after the appearance of signs of progressive or complicating disease.

---

Futherance of the Science of Disease Prevention.—Rittenhouse says that if it is a righteous act to relieve suffering, it must be a still greater one to prevent it, and that the spread of knowledge of preventive medicine has resulted in an extraordinary reduction in the general mortality rate during the last fifty years. For this achievement the press and the layman are entitled to their full share; the chief honor, however, must be given to the medical profession, which has developed the science. They have made every effort to induce people to adopt healthful habits of life, and are to-day leading or prominently identified with every official or unofficial movement in the nation-wide campaign for the conservation of health and life. The medical examiners of life insurance companies have rendered most effective service, although we seldom hear it alluded to. This valuable service could be materially advanced at the cost of very slight effort. The fact that more of our people are coming to appreciate the wisdom of giving their doctors a chance to head off disease is due largely to the medical examiners.—*Lancet-Clinic*, August 22, 1913.

# Book Reviews.

EPIDEMIC INFANTILE PARALYSIS (HEINE-MEDIN DISEASE). By Prof. PAUL H. RÖMER, Principal of the Institute of Hygiene and Experimental Medicine of Marburg. Translated by H. RIDLEY PRENTICE, M.B., B.S., Lond., M.R.C.P.; late Resident Medical Officer to the National Hospital for the Paralyzed and Epileptic, Queen Square. With fifty-seven illustrations in the text. Price $2.75 net. New York: William Wood & Company, 1913.

THE numerous additions that have been made during the past few years to the knowledge of poliomyelitis, both in the clinic and in the laboratory, impart considerable importance to this volume, which gathers the scattered threads of this knowledge. Professor Römer has been active in the experimental study of this disease and is singularly fitted to present a complete and lucid account of its history, epidemiology, etiology, and clinical and laboratory aspects. In short, he has written a monograph on poliomyelitis. In the first chapter he discusses the development of the knowledge of this disease from the early conceptions framed by Heine and Medin to the more recent ideas advanced by Wickmann and others, and in Chapter II describes the symptomatology of the disease in man. In Chapter III he deals with the microscopic and cultural researches, the experimental studies on monkeys, the clinical history of the disease in the latter animals, the nature of the virus, and the use of other animals for experiments. In Chapter IV, which is headed "pathology and pathogenesis," the author, after a historical retrospect of these phases of the subject, describes the distribution and spread of the virus within the organism, contrasts the pathological changes in the experimental disease in monkeys with those found in man, and traces the portal of entry of the virus into the central nervous system. Chapter V comprises a history of the various epidemics of poliomyelitis and a portrayal of the epidemiological characteristics of the several outbreaks. The most important and the most interesting part of this book is that which concerns the fight against the disease, which topic comprises the substance of Chapter VI. The questions of immunity and immunization are here discussed. The results obtained by the author and by other investigators in the immunization of animals and in the detection of specific antibodies, and the experiments with drug and serum therapy are all presented in detail. The measures of prophylaxis are also discussed. A complete bibliography of poliomyelitis comprises a section of nineteen pages. There are a number of illustrations showing the various types of the disease as experimentally produced in monkeys. The translator has ably acquitted his task in rendering the author's language into clear and idiomatic English. The book is well printed on fine paper and well bound. It should prove a valuable addition to the library of the general practitioner.

THE DOCTOR IN COURT. By EDWIN VALENTINE MITCHELL, LL.B., of the Massachusetts Bar. Price $1.00. New York: Rebman Company, 1913.

THIS book discusses the general principles of the law relating to the medical profession. It deals with professional evidence, the contract of the profession, the civil responsibility of the physician, remuneration, confidential communications, the criminal responsibility of the profession, and qualifications. The book is brief and to the point, and is designed to be of distinct service to the general practitioner, warning him of the many legal pitfalls that he is apt to meet in the course of his work.

A CLINICAL MANUAL OF MENTAL DISEASES. By FRANCIS X. DERCUM, M.D., Ph.D., Professor of Nervous Diseases Jefferson Medical College, Philadelphia; Consulting Neurologist to the Philadelphia General Hospital, President of the Philadelphia Psychiatric Society, ex-President of the American Neurological Association and of the Philadelphia Neurological Society, Foreign Corresponding Member of the Neurological Society of Paris, and of the Neurological and Psychiatric Society of Vienna; Member of the Royal Medical Society of Budapest, etc. Price, $3 net. Philadelphia and London: W. B. Saunders Company, 1913.

THIS author is best known perhaps from his neurological contributions to medicine. He is pleased to state in his preface that his manual, as prepared from his lectures at the Jefferson Medical College, is written purely from the clinical standpoint. The psychological interpretation of the symptoms of insanity occupies but a small part of the text. The author's aim has been to instruct the student and the family physician in such a way that they may know how to recognize mental diseases, even in their early stages, that they may know when to commit and when not to commit the patient to a hospital, and that they may understand how to select the proper treatment for the case. He believes that the psychiatry of the present day is too largely speculative and metaphysical, and that our knowledge of mental diseases must advance, not only in the direction of psychological interpretation, but also in what he considers the more important direction of internal medicine. The book is divided into four parts. Part I. contains a description of "the five fundamental groups of mental affections," viz., delirium, confusion and stupor; melancholia, mania, circular insanity; the heboid-paranoid group (dementia præcox, paranoia); the neurasthenic-neuropathic insanities (psychasthenias), and the dementias. Part II. comprises the consideration of the relation of insanity to various somatic affections (infections, intoxications, disorders of metabolism, diseases, pregnancy, etc.); second, the relation of mental diseases to age epochs; and, third, certain mental disorders not usually included under insanity, and also insanity by contagion. Part III. (seventeen pages) is devoted to the psychological interpretation of symptoms. Part IV. is given over to treatment. The style of the book is clear and interesting. There are no histories published at length to illustrate the various types, but symptoms of special cases are introduced for the purpose. The book is commendable as a manual, or more or less brief presentation of the subject, and is not intended as a text book, or as an advanced psychiatric treatise.

TEXT BOOK OF THE DISEASES OF THE NOSE, THROAT, AND EAR. For the Use of Students and General Practitioners. By FRANCIS R. PACKARD, M.D., Professor of the Diseases of the Nose and Throat in the Philadelphia Polyclinic Hospital and College for Graduates in Medicine; Aurist to the Out-Patient Department of the Pennsylvania Hospital. Second Edition, with 145 Illustrations. Price, $3.50. Philadelphia and London: J. B. Lippincott Company, 1913.

ONLY four years have elapsed since the first appearance of this book, but so many strides have been made in the progress of laryngology and rhinology that the rewriting of many portions of the book has become necessary. In the present edition an effort has been made to incorporate such advances. It has been necessary to rewrite entirely the section dealing with diseases of the tonsils and adenoid growths and also to incorporate the description of the processes employed in direct tracheobronchoscopy and esophagoscopy. The author's original purpose in writing this book was to furnish a practical handbook for the use of the undergraduate student and for those taking postgraduate work. The post-graduate work of physicians here and abroad makes it necessary for them to have a reliable guide. It has been the author's aim to provide such information as is essential to help the student in his practical work and to burden his book with as little theoretical knowledge as he could. The book is based on the author's years of experience as a postgraduate teacher and his hospital work in large clinics. His intimate contact with the students of the Philadelphia Polyclinic Hospital and College for the Graduates in Medicine for some years past has made him capable of realizing their needs.

PATHOLOGISCH-ANATOMISCHES PRAKTIKUM FÜR STUDIERENDE UND ÄRZTE. Von Professor Dr. Med. RICHARD OESTREICH, Privat Dozent an der Universität und Prosektor des Königin Augusta Hospitals zu Berlin. Preis, 2 marks. Wien und Berlin: Urban & Schwarzenberg; New York: Rebman & Co., 1913.

THIS handbook in dictionary form of pathological anatomy contains lucid explanations of the different methods of examination of fresh organs and of general pathological anatomical diagnoses. An excellent index renders Professor Oestreich's manual very convenient for students and the overworked general practitioner.

JAHRESBERICHT DER GESELLSCHAFT FÜR NATUR UND HEILKUNDE IN DRESDEN. Sitzungsperiod, 1912-1913 (Oktober, 1912-Mai, 1913). München: Verlag von J. F. Lehmann, 1913.

AMONG the most interesting articles in this year's report of the Dresden Society for Natural History and Therapeutics are the following: Opsonogen Treatment of Furunculosis and Acne, by Dr. von Einsiedel; Ophthalmological Diagnosis of Diseases of Accessory Nasal Cavities, by Dr. Meyer; Production of Tumors by Homogeneous and Heterogeneous Embryonal Cells, by Dr. Kelling; Human Parasites, by Professor Brandes, and Water Supply for Country and Town, by Dr. Thiersch. There is also an account of the visit of the members of the society to the Rhythmical Gymnastic School of Jacques Dalcroze in Hellerau near Dresden, and the subsequent recommendation adopted by the society that the Delcroze system should be introduced into the German public schools as excellent exercise for the body and the mind.

A MANUAL OF X-RAY TECHNIQUE. By ARTHUR C. CHRISTIE, Captain Medical Corps, U. S. Army; Instructor in Radiology and Operative Surgery Army Medical School, Washington, D. C. With 42 Illustrations. Price, $2. Philadelphia: J. B. Lippincott Company, 1913.

THE small number of medical officers in the service of the United States Army necessitates a frequent change of station, so that it often becomes imperative for one to familiarize himself in a comparatively short time with the essentials of radiology. Captain Christie's book is limited to the absolute essentials of *x*-ray examination of the head, the thorax, the alimentary canal, and the urinary system, and to the localization of foreign bodies and fluroscopy. Resort to a specialist whenever his services can be obtained is candidly advised by the author.

FRACTURAS DEL FEMUR Y EN TRATAMIENTO. Por El Dr. S. GARCIA HURTADO. Madrid: Imprenta de San Francisco de Sale, 1913.

PROFESSOR HURTADO reviews the fractures of the thigh and their therapy. For their diagnosis he believes radiography indispensable and advises an antero-posterior projection of the affected joint with the leg extended and approaching the middle line as much as possible while the radiogram is being taken. Another radiogram should be made with the leg separated from the middle line as far as possible. Eight original radiograms and forty-five text illustrations complete this very clear and detailed treatise.

MINOR OPERATIVE SURGERY. By DUNCAN C. L. FITZ-WILLIAMS, M.D., Ch.M., F.R.C.S. (Eng.), F.R.C.S. (Edin.), Surgeon in Charge of Out-Patients St. Mary's Hospital, Senior Assistant Surgeon to Paddington Green Children's Hospital, Lecturer on Clinical Surgery, and Joint Lecturer on Operative Surgery St. Mary's Hospital Medical School. Price, $3.75. 446 pages. New York: William Wood & Co., 1913.

THIS book is intended chiefly for the student and young surgeon, although even the F.A.C.S. of long standing may learn something from it. An attempt has been made to add the chief points in surgical and surface anatomy, with a good deal of success. A timely introduction is afforded by the first chapter on general considerations, which includes the examination of the patient, preparation for the operation, sepsis, antisepsis and asepsis, and general principles. Some of the main chapters treat of ligatures of arteries, operations on nerves, amputations and disarticulations, osteotomies, operations on the air passages, alimentary and genitourinary tracts, on the head and breasts, harelip, cleft palate, plastics, tendons. Each of these subjects is taken up systematically and treated in a most satisfactory manner.

KRANKHEITSENTSTEHUMG UND KRANKHEITSVERHÜTUNG UND GEHEIMSNISSVOLLE LEBENSÄUSERUNGEN DES KÖRPERS. Offentliche im Hamburgischen Vorlesungsgebäude in den Winter 1911 und 1912 gehaltene Vorlesungen von Dr. HANS MUCH, Oberarzt am Eppendorfer Krankenhaus. Mit 22 Abbildungen im Text. Pages 117. Price Mks. 2.50. Würzburg: Verlag von Curt Kabitsch. 1913.

THIS series of lectures deals with the latest problems in medicine with reference to the causation and prophylaxis of disease. The subjects of some of the lectures are: 1. The Instigators of Disease—immunity, natural immunity, science and philosophy. 2. Acquired immunity, the protective agencies, their injury, etc. 3. Acquired immunity, tetanus, bacilli carriers, meat and sausage poisoning, etc. 4. Individual diseases, syphilis, recurrent fever, frambesia, the plague, etc. 6. Tuberculosis. 7. Miscellaneous. The articles are written in an interesting semi-popular philosophical style.

THE PRINCIPLES AND PRACTICE OF GYNECOLOGY. For Students and Practitioners. By E. C. DUDLEY, A.M., M.D., ex-President of the American Gynecological Society, Professor of Gynecology Northwestern University Medical School, Gynecologist to St. Luke's Hospital, Chicago; ex-President of the Chicago Gynecological Society, one of the Founders of Congrès Périodique International de Gynecologie et d'Obstetrique, Fellow of the Royal Society of Medicine, England, Surgeon to the Medical Reserve Corps United States Army. Sixth Revised Edition, with 439 illustrations and 24 full-page plates in colors and monochrome. Price, $5 net. Philadelphia and New York: Lea & Febiger, 1913.

THE appearance of six editions of this work within a period of fifteen years is sufficient proof of its popularity. The present edition maintains the high standard which has characterized this book in the past. The subject matter has been carefully revised and has been brought strictly up to date. One admirable feature of this work is the arrangement of its topics in pathological and etiological sequence. Thus infections and inflammations, such as vulvovaginitis, metritis, salpingitis, ovaritis, and peritonitis are considered together. The illustrations, of which there are a large number, are striking for their originality and artistic excellence. Those that show the various steps of operations, as perineorrhaphy, are particularly helpful. The work is eminently practical, both in its detailed description of operative procedures and in its ample exposition of the non-operative measures of treatment. One need have no hesitation in recommending this book to the student and practitioner as one of the best in its line.

THE PRACTICAL MEDICINE SERIES. Comprising Ten Volumes on the Year's Progress in Medicine and Surgery. Under the General Editorial Charge of CHARLES L. MIX, A.M., M.D., Professor of Physical Diagnosis in the Northwestern University Medical School. Volume IV. GYNECOLOGY. Edited by EMILIUS C. DUDLEY, A.M., M.D., Professor of Gynecology, Northwestern University Medical School; Gynecologist to St. Luke's and Wesley Hospitals, Chicago, and HERBERT M. STOWE, M.D., Associate in Gynecology, Northwestern University Medical School; Attending Obstetrician to Cook County Hospital. Series 1913. Price $1.35. Chicago. The Year Book Publishers.

THE book is divided into five parts: General Principles, Infections and Allied Disorders; Malformations and Tumors, Traumatisms and Displacements. The arrangement is valuable, as it enables one to readily review any gynecological subject. Many interesting and instructive cases are recorded.

TREATMENT OF INTERNAL DISEASES. For Physicians and Students. By Prof. NORBERT ORTNER, of the University of Vienna. Edited, with Additions, by NATHANIEL BOWDITCH POTTER, M.D., Assistant Professor of Clinical Medicine at Columbia University (College of Physicians and Surgeons), New York; Visiting Physician to the New York City Hospital and to the French Hospital. Translated by FREDERICK H. BARTLETT, M.D., Instructor of Children's Diseases at Columbia University (College of Physicians and Surgeons), and Attending Physician to the Babies' Hospital. Second Edition in English Revised and Reset, from the Fifth German Edition. Price $5. Philadelphia and London: J. B. Lippincott Company.

AFTER reading portions of this volume the wonder grows how the phrase "therapeutic nihilism" ever came into existence. The author presents a most comprehensive exposition of therapeutic science, including not only the medicinal aspects of the subject, but also its mechanical, dietetic, climatic, hydrotherapeutic, and other physical phases. The book is eminently practical. There are numerous prescriptions which are made to conform to the American Pharmacopeia. The translator has brought to his task a sympathetic knowledge of his subject and the command of idiomatic English. A wide sphere of usefulness is predicted for the volume.

# Society Reports.

## NEUROLOGICAL INSTITUTE OF NEW YORK.

*Reports of Weekly Clinical Conferences.*

FIRST DIVISION—DR. JOSEPH COLLINS.

**An Unusual Case of Polyneuritis.**—Dr. FREDERIC M. HANES presented a patient with symptoms and signs which have not been altogether easy to interpret. Her history is that of progressive muscular weakness with muscular atrophy, and the diagnostic difficulty has been definitely to localize the site of the lesion in the spinomuscular neurone. Her history follows:

The patient, a married woman of 55, of American birth, comes complaining of difficulty in walking, especially in walking upstairs; weakness of both legs and rapid fatigue of the legs upon exertion. She has been married 30 years and has had two miscarriages but no children. Her husband is alive and well. The family history is negative. She says she has always been a healthy robust woman, having had no serious illness since childhood. As a child she had measles, mumps, and pertussis without complications or sequelæ. She has never been of a nervous disposition and has not suffered from headache. She has always been fond of alcoholic drinks. Alcohol gives her a sense of pleasurable exaltation but even in large quantities does not confuse or depress her. Some nine years ago, about the time of her menopause, she felt very nervous and excited and at this time drank large quantities of alcoholic drinks. She usually drank whiskey, and consumed as much as a pint a day. During the past two or three years she has used alcohol very sparingly—a glass or two of beer daily. Six or seven years ago she suffered from "prickly sensations" in the hands, legs, and feet. She likewise had paresthesia at this time, consisting of crawling sensations in both legs and feet. All these subjective sensory disturbances passed away before the muscular weakness of which she now complains began.

After recovering from a sprained ankle five years ago she noticed that the right leg seemed weaker than the left, and this weakness made it difficult for her to step upon the curb without stumbling. This condition progressed very gradually; the left leg also began to feel weak, and the weakness of both legs necessitated her helping with her arms by pulling upon the hand-rail in ascending stairs. It required about three years for the development of the weakness of the legs to a stage in which walking was seriously hindered. The patient says the weakness of her legs preceded the wasting by some two years. It is only within the past three years that she has noticed the legs becoming smaller. The calves of the legs seemed to waste first. All her symptoms have been more pronounced during the past two years and she says she is growing progressively worse. Both legs have grown weaker gradually, though she is still able to walk with a cane, and the legs have grown much thinner from the hips down. She has had no lancinating pains in the legs at any time. After severe exertion or fatigue from standing, her calves often ache and sometimes she has a dull pain in both thighs. These symptoms have come on only in the past two years. During the past few years she has had urgency of urination with an occasional loss of urine when unable to void at once. This symptom is worse when she is fatigued from standing or walking. The bowels are regular. Her general health has been excellent.

*Physical Examination.*—The patient is a bright, intelligent woman, of well nourished appearance and healthy color. There are no cranial abnormalities, no glandular enlargements. The thyroid is not palpable. The heart, lungs, and abdomen are negative. The skin is normal. She is mentally normal and there is no disturbance of function of the cranial nerves. Both pupils are irregular in outline but approximately equal in size. They react to light and in accommodation. There is hippus of both pupils. No abnormalities of sensation can be elicited; both superficial and deep sensibility are normal. The superficial reflexes are normal, as are the deep reflexes of the upper extremities. The left knee-jerk and ankle-jerk can be elicited. The right knee-jerk is weakly present, the ankle-jerk absent. The musculature of the face, upper extremities, and trunk is normal. There is no wasting of the small muscles of the hands. There is weakness and wasting of all the muscle groups of both lower extremities. The flexors of the legs and feet are weaker than the extensors. The muscles are flaccid, atrophic, and soft. She walks with a steppage gait. The feet are held widely separated, are lifted rather high, only slightly dorsiflexed, and are brought down quickly. This gait is more marked in the right leg. No Rombergism. The electrical examination of the muscles reveals a marked hyposensibility to electrical stimulation of both nerves and muscles of the legs for the faradic and galvanic currents. There is no reaction of degeneration. The Wassermann reaction is negative in the serum and cerebrospinal fluid, and there is no pleocytosis or excess of globulin.

These symptoms and signs, together with the history of immoderate use of alcohol, have convinced us that the patient is suffering from alcoholic polyneuritis. The case is far from typical, however, in that the objective findings are exclusively those due to motor neurone injury. Sensory symptoms, both subjective and objective, may be very slight in alcoholic neuritis, but it is rare, I believe, to have them so nearly absent from the picture as they are in this case. On first sight the patient's gait and the location of the atrophy suggests a primary muscular lesion —a dystrophy. Considering her age, the distribution of the atrophy, and the absence of any heredito-familial history, however, we may with confidence exclude this condition.

SECOND DIVISION—DR. FREDERICK PETERSON

**Case of Brain Tumor.**—Dr. FOSTER KENNEDY presented a case of tumor in the left temporosphenoidal lobe involving or producing pressure on the mid-brain especially the corpora quadrigemina.

T. D. aged 24 years was admitted to the Neurological Institute on October 8, 1913. His present illness dates from four months ago when he began to suffer from severe headaches: these have been persistent and progressive. In early September he began to have attacks of vertigo of indefinite character, of a severity to interfere with walking: he lurched chiefly to the right side.

About the same time the right eye began "to turn in" and he complained of seeing double; he also told of seeing objects "like ghosts" and of frequent subjective sensations of smell and taste. There has been occasional vomiting, and for some days before admission considerable stupor has become evident. Both pupils are small and without reaction to light or on accommodation. Conjugate movements of the eyes in upward and downward directions are almost completely abolished. No hemianopia. Paretic jerking of the eyeballs on looking to the right and left sides. Gross papilloedema in both fundi. There is a weakness of the right side of the face of supranuclear type. There is no ataxia demonstrable in any of the extremities. Marked weakness in right arm and right leg. No atrophies. All deep reflexes in right arm and leg much brisker than on the left side.

Abdominal reflexes: Right, absent; left, present.

Plantar reflexes: right, extensor; left, flexor.

Considerable defects in word-memory. When shown his rosary, he said it was "a bit of brass" but could not name it. A key was identified as "matches" which error was repeated for several other objects immediately afterwards shown to him. This patient has in the ocular symptoms

the typical and well known complex produced by lesions in the region of the quadrigeminal bodies. His marked increase in weight,—twenty pounds in the last six months—with his eye symptoms might point to a tumor originating from the pineal gland. In such growths, however, by the blocking of the iter and the rise in ventricular pressure there is produced bilaterally equal pressure on the two pyramidal tracts. In this case, evidence of such pressure obtains only on the right side of the body. This fact together with the failure in word-memory would seem to point to the gradual spread to the mid-brain of pressure from the left temporosphenoidal lobe. If credence be placed in the history of subjective visual, gustatory, and olfactory sensations, then the probability of this tumor being primarily temporal and secondarily quadrigeminal becomes much increased.

Dr. Elsberg punctured the corpus callosum in a vain attempt to withdraw fluid from the ventricles. In pineal growths the ventricles are much dilated. A tumor pressing mesially from without would compress the ventricle and diminish its cubic space. Therefore perhaps it is justifiable to consider the result of this operation as being in itself of diagnostic significance.

**Juvenile Paresis.**—Dr. Peterson presented J. H., Age 20. Errand boy. This patient was referred by one of the eye hospitals for opinion as to his mental status. The only symptom of which he complains is failing eye sight, but investigating his past life we find that birth was normal. He is one of four living children, the others being in good health. He talked at 18 months. Walked at 2 years. Started schooling at 5 years, but did not progress very well. At 8 years of age began to play truant frequently, but he learned to read, write, and spell fairly well. At age of ten began to smoke cigars and take an occasional drink. His companions were always boys much older than himself and not of the best moral character. There is an indefinite history of excessive indulgence in alcohol, but no direct corroboration can be obtained. Examination reveals a simple, expressionless facies. Test words poorly performed. There is considerable mental confusion. Eyesight poor, practically no vision in right. Pupils are fixed and irregular, the right considerably irregular. The upper jerks are present as equal. The reflexes of the lower extremities were difficult to elicit, but being elicited are fairly active. The platar responses are flexor. No clonus. Abdominals and epigastrics are present and equal. There is a general hypoesthesiæ to pain stimuli, and on first examination abolition of conjunctival reflexes.

Serology. Serum Wassermann positive. Spinal fluid Wassermann, positive 8 cells, excess of globulin, Fehling reduced. Routine blood examination negative. Gold chloride positive. Eye report Dr. Holden: No perception of light in right eye, L 5/200. L. marked concentric contraction fields. Simple optic atrophy R. > L. Binet-Simon test places boy at 8.2 years.

No subjective history of hereditary syphilis could be obtained, but mother has irregular pupils L. > R., fixed to light and shows a positive serum Wassermann.

THIRD DIVISION—DR. PEARCE BAILEY.

**Case of Cerebellar Embolism.**—Dr. Louis Casamajor presented H. E., 29 years old, Norwegian servant maid who entered the service of the Third Division of the Neurological Institute complaining of difficulty in walking and dizziness. The family history was negative as far as neurological disease was concerned. As a child the patient had had an acute attack of "heart disease" from which she recovered with no subjective residual. Had two attacks of pneumonia in the past nine years. No history of syphilis. The patient had always been well except for the above acute illness and worked as a domestic servant. Five weeks ago she began to complain of pain and some numbness in the legs. These pains, while rather severe, did not interfere with her work and began to recede after two weeks. Two weeks ago the patient suddenly became dizzy and could not stand alone. With this onset there was no headache or eye symptoms nor did the patient lose consciousness. She was obliged to go to bed on account of the dizziness and has not been able to work since. When she got out of bed she experienced great difficulty in walking, due to insecure balance, with a tendency to fall forward and to the right. There has been no change in her condition for the past week. At no time has there been any bladder disturbance.

Physical examination on admission showed a fairly well developed young woman whose gait and station were decidedly unsteady. The deep reflexes of the arms were present and equal as likewise were the abdominals and epigastrics. The knee jerks and angle jerks could not be obtained on either side. There was no clonus or Babinski. There was some slight swinging ataxia of all extremities, more marked in the legs. Asynergia marked; adiadochocinesia negative. Sensations were normal throughout.

Eye examination by Dr. Holden showed the pupillary reaction normal and equal. Ocular movements very normal. There was no diplopia. She had a high degree of myopia in both eyes with a vision of something less than 20/200 and the fundi showed the usual changes of high myopia. The nystagmus was of interest. Looking straight ahead no movement of the eyes was observed. Looking to the right there was slight, slow, horizontal, and rotary mystagmus to the right. On looking to the left the mystagmus to the left was much more marked and rapid than the other. On looking upward and downward no nystagmus was seen. No changes could be found in any other of the cervical nerves and especially was there no diminution of hearing acuity for the patient heard the watch tick at three feet from either ear.

Examination of the heart showed that the left border percussed five inches from the median line while the right border did not extend beyond the right border of the sternum. On auscultation there was a loud diastolic and a soft systolic murmur heard loudest to the left of the sternum in the second and third intercostal spaces. The diastolic murmur was transmitted in all directions. We considered the murmur to indicate an aortic regurgitation with some stenosis. The systolic blood pressure in the right arm was 125 mm. and the diastolic 85 mm. Wassermann in serum negative. Spinal fluid: Wassermann negative. Globulin negative. No cells.

*Interpretation.*—A young woman of 29 years, with a severe heart lesion following an early acute endocarditis, suffered from dizziness and instability of gait and station of acute onset. Neurological examination shows instability of gait and station with asynergia. Slight swaying ataxia, lost knee jerks, and some cerebellar nystagmus most marked on looking to the left. The localization of cerebellar lesions is still hazardous but this case is put forward as one of cerebellar lesion on the following points: (1) Vertigo and instability of gait and station. (2) Horizontal and rotary nystagmus which is more likely of cerebellar origin than of vestibular as the hearing is the same in each ear. (3) The absence of pyramidal or other tract signs. The absence of knee jerks.

The rapid onset and the presence of an extensive cardiac lesion in this patient justifies the diagnosis of embolism in the cerebellum.

---

**An Immaculate Profession.**—In some countries it seems to be understood that if a physician calls in a surgeon to perform an operation the fee for the operation is to be shared. We have never heard of this being done in England, nor is it thinkable that the idea has ever been entertained in any part of our far-reaching Empire.—*British Medical Journal.*

## NEW YORK ACADEMY OF MEDICINE.

### SECTION ON LARYNGOLOGY AND RHINOLOGY.

*Anniversory Meeting, Held November 25, 1913.*

Dr. William W. Carter, in the Chair.

This meeting consisted in exercises commemorating the Fortieth Anniversary of the Section which was originally the New York Laryngological Society. The tablet presented was inscribed as follows:

The New York Laryngological Society, founded by Clinton Wagner, M.D., merged with the Section in Laryngology and Rhinology of the New York Academy of Medicine Eighteen Hundred and Eighty-five. The oldest Society of Laryngology in Existence. This Tablet Commemorating its Fortieth Anniversary Presented by David Bryson Delavan.

**Reading of Congratulatory Letters.**—Dr. C. D. Van Wagenen, the secretary, read congratulatory letters from Dr. Thomas Rushmore French of Brooklyn, Dr. George M. Lefferts of New York, Dr. William Kelly Simpson of New York, Dr. John M. Mackenzie of Baltimore, Dr. Herbert S. Birkett of Montreal, Dr. Francis R. Packard of Philadelphia, and others.

**Introductory Remarks.**—The President, Dr. William W. Carter, made this brief address. He said that he congratulated the Section and welcomed the guests of the evening with a feeling of keen appreciation of the honor of presiding at such a meeting together with a sense of unworthiness in assuming the chairmanship on this occasion. This was an epoch in their history. They had met not from necessity nor to applaud their own work, but to honor those pioneers who had lifted laryngology from a cradle of obscurity to its present position. The span of one life was too short for the founder to realize all that he had done, but he knew that he was building for those who were to follow him. They had with them one who had come from London to be with them on this occasion, Dr. Wagner, who had graduated at the beginning of the Civil War and had served in the Medical Corps of the army during the war. This experience placed him in the first rank as a surgeon in that day. He then went to Vienna and studied laryngology and when he returned opened a laryngological clinic in this city. This clinic was the beginning of the Metropolitan Throat Hospital. Dr. Wagner was instrumental in founding the New York Laryngological Society in 1873 which later became the Laryngological and Rhinological Section of the New York Academy of Medicine.

**Address of the Founder.**—Dr. Clinton Wagner made this address (see page 1).

**Address of Commemoration and Presentation.**—Dr. David Bryson Delavan made this address (see page 2).

**Acceptance of Commemorative Tablet and Memorabilia.**—Dr. William Wesley Carter made this address. He declared that this tablet commemorating the Fortieth Anniversary of the Laryngological Section of the Academy of Medicine, was a record to posterity of the distinction of the birth of the section, and the wonderful collection of memorabilia bearing upon its early history, and the remarkable collection of historic instruments, showing the ideas from which many of the most useful instruments of today had been evolved created a shrine, to which members could ever look for inspiration. The section recognized with grateful appreciation the professional pride of the donor and pledged itself to maintain the high standard upon which the society was founded. The section had wielded a distinct influence in their specialty and had contributed its full share to its unparalleled growth. It was well, therefore, for those who had come upon the arena after the first great battles had been fought and won to know whence came the enthusiasm that had achieved these results. There was no specialty that had advanced more rapidly than laryngology; only a few years ago it received but a modicum of respect, and its followers were almost ostracized by the general profession; but all this was now changed and it was recognized as a calling worthy of the best efforts of the most skillful men in the profession. Laryngology was the child of necessity and was endowed with those sturdy characteristics especially designed to overcome difficulties. The position which it now occupied was due to the character of the men who had embraced it, so that, while utilizing the gains of science they should not fail to appreciate the dignity and worth of those from whom their knowledge had been obtained. At no time in the history of laryngology had there been so many good men engaged in devising new methods and in perfecting the old, and to even mention the new and efficient procedures for relieving abnormal conditions that arose in their field of effort would require more time than was at his disposal. One instance, however, that of the bronchoscope must be mentioned. This instrument had opened up a new field for the laryngologist, and its wonderful possibilities, which were only just beginning to be realized, should be published throughout the length and breadth of the land, so that every layman might know that when a foreign body became lodged in the air passages it might be removed under the direct guidance of the eye by one skilled in the use of this wonderful instrument. This section had contributed largely to the advances of their science. There were men present whose accomplishments had not only been admired in this country but who were recognized in foreign parts and whose work claimed a place of distinction in the literature of every country in the world. These were the men who had drunk deep of the astral wines, and who could see, engraved on the stars themselves, the great future of their specialty. This bronze tablet was a fitting tribute to the oldest laryngological society in the world and should occupy an appropriate place on the walls of this Academy.

Dr. Douglas Beaman said that he had been thinking that the generation to which he belonged was in the third rank. First came the pioneers with high boots and axes who hewed the path; then the teachers who had taught him, and these too were giants. Their methods were not always perfect but they had the right spirit and high ideals. They, themselves, belonged to the third rank and they, too should be proud of their work; they were still forging ahead. Three great revolutions had come since his association with laryngology. First, there was the great advance brought about by the use of clean methods, which had resulted from a knowledge of the part played by bacteria in causing infection. Second, and perhaps even more important, was the discovery of cocaine, in 1884, by which their work had been revolutionized in the very best sense of the word. The third great revolution had been a natural evolution, that was, an improvement in method. There had never been such an active tide, such a wave of progress as was now sweeping over their specialty.

Dr. Robert C. Myles said that on such an occasion one's feelings were mingled. They should bow their heads in reverence and place laurels on the heads of the living and chaplets of immortals on the graves of the dead. It was with a sense of gratitude that they paid tribute to their teachers, who had only required of them that they should be a credit to themselves. Twenty-seven years ago he came from the forest and had straggled into Dr. Wagner's clinic and he still recalled much that he had learned there that had been very helpful to him. Dr. Myles said that he believed that occasions like this were of more value to them than twenty scientific meetings because, after all, it was the spirit that made the world move on. They were apt to lose their constructive feelings and to become pessimistic, and while it was right that they should fight things that would not stand the scientific test, it was not well to lose sight of the constructive side. It seemed that when one compared what those pioneers accomplished with so little with what they were doing today that they suffered by the comparison.

The meeting was closed by a rising vote of thanks to Dr. Delavan and Dr. Wagner.

---

## THE PRACTITIONERS' SOCIETY OF NEW YORK.

*Two Hundred and Fifty-sixth Regular Meeting, Held October 10, 1913.*

The President, Dr. Walter B. James in the Chair.

**Spontaneous Rupture of the Spleen in Typhoid Fever: with Report of a Case Cured by Operation.** Dr. William A. Downes reported this case. He said that spontaneous rupture of the spleen in the course of typhoid fever was sufficiently rare to warrant the report of a case; more especially as, in this instance, it was possible to make the diagnosis, and, by prompt operation, to save the life of the patient. Only twelve other cases were recorded in the literature. In nine of these the condition was discovered at autopsy. In the three remaining cases it was found in the course of operation for supposed intestinal perforation. None of the cases recovered.

The case was that of a physician, thirty-six years old, who was admitted to the New York Hospital on February 20, 1913, with the diagnosis of probable typhoid fever. He had never been seriously ill before, and especially had never had malarial fever or any other disease likely to lead to enlargement of the spleen. Physical examination on date of admission showed noth-

ing unusual for the stage of the disease he was suffering from, except that the area of splenic dullness was unusually large and extended from the eighth to eleventh rib and anteriorly three c.m. beyond the costal margin. The edge of the spleen was distinctly felt even with quiet breathing. On deep inspiration it extended fully four c.m. below the costal margin. It was unusually broad, its edge blunt and rounded and its consistence noticeably firm and tense. On the day after admission the patient complained of a sudden, severe, sharp, stabbing pain in the left hypochondrium. This was soon followed by severe aching pain in the left shoulder, which radiated somewhat down the left arm. Soon after the onset of the pain he vomited a small quantity of clear fluid and broke into a profuse perspiration. The pain was so severe as to require an injection of morphine. The respirations were rapid and shallow; there was marked tenderness to pressure just below the costal margin, where the spleen could be distinctly felt, and slight rigidity of the upper part of the left rectus muscle. At times the pain was felt somewhat in the right hypochondrium. The patient looked very seriously ill the next day; the severe pain in the left hypochondrium and left shoulder having continued throughout the night. The area of splenic dullness seemed larger than on admission. Elsewhere the abdomen was soft and showed no tenderness on palpation. His condition improved in the next twenty-four hours. Pulmonary infarct was suspected, but neither the signs nor the symptoms were sufficiently characteristic to justify that diagnosis. The extremities showed no indication of thrombophlebitis. Blood cultures taken the day after admission were now reported as containing a Gram-negative bacillus, which was later positively identified as the bacillus typhosus. On the morning of February 25 the patient had an attack of coughing and immediately afterward complained of the same severe pain in the left hypochondrium and left shoulder. This pain continued throughout the morning and was accompanied by profuse sweating and by a startling change for the worse in the patient's general appearance and condition, similar to the one observed after the first attack of pain. Examination of the chest still showed no change from that of the preceding days. There was dullness on percussion over the greater part of the left side of the abdomen and in the left flank, and some rigidity and tenderness in the left upper quadrant. The rest of the abdomen was soft and flat, and, while having a somewhat boggy feel, was not tender. The patient was seen by Drs. Conner, Downes, and Lambert, and all agreed that the symptoms indicated a rupture of the spleen. This diagnosis was arrived at by considering the location of the pain, tenderness and muscular rigidity; by the absence of signs pointing toward other possible complications such as intestinal perforation and pulmonary infarction, and, finally, by the fact that the spleen has been recognized as being unusually large and tense for the early days of typhoid fever. A blood examination made some three and a half hours after the onset of the pain, and when the symptoms pointed strongly to an alarming loss of blood, showed the following surprising results: red cells, 5,280,000; hemoglobin (Sahli), 85 per cent.; leucocytes, 35,000. In spite of these apparently inconsistent blood findings, an immediate exploratory operation was decided upon and the patient was taken to the operating room five and a quarter hours after the onset of the symptoms. Dr. Downes, under local anaesthesia, opened the abdomen by a vertical incision through the middle of the left rectus muscle. Upon opening the peritoneum, the abdomen was seen to contain a great quantity of blood. The patient was therefore given nitrous oxide and ether and the incision rapidly enlarged. A tremendous quantity of fresh and clotted blood, estimated at from one and a half to two quarts, escaped from the abdomen. The spleen was then delivered through the wound, the pedicle being caught with a long straight rubber-covered clamp, placed close to the spleen. The vessels were ligated, the spleen removed, and the larger blood clots taken out of the abdomen—one old and laminated clot fully an inch thick and conforming to the size and shape of the phronic surface of the spleen being found high up under the diaphragm. The abdomen was closed without drainage. When the spleen was first explored with the hand a rent in its capsule fully three inches in length was encountered running along its posterior border; during the further manipulations the capsule was stripped from almost half its surface. In spite of the patient's critical condition on the operating table he improved steadily in the following few days. On the night of the day of operation his hemoglobin was 62 per cent. and his leucocytes 68,000. The next day his hemoglobin was 58 per cent.; red cells, 2,810,000; leucocytes, 36,400. During the further course of the disease the patient, despite a complicating thrombophlebitis and pulmonary infarct, improved steadily and left the hospital on March 31. One month later he had regained his weight and seemed in his usual health.

In answering inquiries from the members present, Dr. Downes said that as far as he knew patients deprived of their spleen by operation got along as well as normal persons. At least this was the usual history in such persons in whom the spleen had been removed after some accidental injury to the organ; that is, traumatic cases. He had also seen recovery in cases of splenomegaly of the Gaucher type, after removal of the spleen; of course in this condition the withdrawal of the functions of the spleen from the general organism was gradual as the spleen tissue was replaced by the new growth and it was thought that the bone marrow in the mediastinum took up some of the functions of the organ.

**The Serological Tests in Cerebral Hemiplegia.**—Dr. CHARLES L. DANA read this paper. (See Vol. 84, p. 1013.)

**Unresolved Pneumonia.**—Dr. JOHN S. THACHER read this paper. (See page 7.)

Dr. JAMES said that he quite agreed with Dr. Thacher as to the importance of radiographs in pointing out the localization of fluid in the chest. He was also not inclined to grant that radiographs are very important in differential diagnosis of the various conditions that may follow pneumonic inflammation of the lung; that is, a radiograph tells little or nothing about the nature of the shadow seen, but tells a great deal about its site and the necessity of exploration with the needle to decide upon the nature of the condition. Dr. James thought, too, that while the dangers of exploration with the needle were real, still, in his opinion, the needle was used rather too little than too much in routine practice of physicians. Dr. Thacher brought out clearly the unreliability of the usual signs and symptoms of pus in the chest and valuable time is lost if exploratory puncture, repeated if necessary, is not made.

Dr. ROPER said that it was his opinion that one saw at least one case a year in hospital practice in which the patient left the hospital with physical signs of consolidation still present but with nothing to suggest pus. He could recall two autopsies in the last five years in which cases which had given similar signs showed consolidation with beginning organization. It was the routine practice at New York Hospital to operate upon cases of empyema even before pus in the exploratory syringe was evident to the naked eye. If the fluid was turbid and the number of polynuclear leucocytes was very considerable on microscopic examination, operation was thought to be indicated. He thought that the experience at the New York Hospital showed that this was a better routine rule than waiting for the appearance of frank pus, especially in empyemata of children. On the other hand, one child in whom operation had been delayed for some reason eventually recovered without operation. This was unusual.

## SOUTHERN MEDICAL ASSOCIATION.

*Seventh Annual Meeting, Held at Lexington, Kentucky, November 17, 18, and 19, 1913.*

THE PRESIDENT, DR. FRANK A. JONES OF MEMPHIS, TENNESSEE, IN THE CHAIR.

(*Concluded from Vol. 84, p. 1145.*)

**The Management of Proteins and Fats in Infant Feeding.**—Dr. A. W. CALLOWAY of Asheville said that one very important estimation must be considered in connection with proteins, namely, for a baby to thrive it must have 1.5 grams of proteins per kilogram daily, even though the caloric estimation might be in excess of daily requirements. The consequence was the sufficient number of protein calories. These could not be supplied with either fats or carbohydrates. Such was not the case with the two latter. Clinically speaking, there was a disturbance in the protein digestion if the following group of symptoms prevailed. First, they would describe those where proteins were in excess. Failure to gain weight, constipation, the presence of large, hard, casein curds in the bowel movements. Under the condition of an excess of proteins the management would consist in increasing the per-

centage of sugar and lowering that of the proteins. A considerable portion of these might be given in the form of whey. The casein might be rendered more digestible by adding starch to the food. Again, the milk might be pancreatinized. Having pointed out most of the clinical evidences of excess of fats, a reduction in it was the remedy, and in making this reduction it was better to go to a low point, as far as even one per cent. and then make additions as rapidly as results would justify. When babies were vomiting it was a safe rule to keep the fats low. Fat starvation was soon manifested by a condition of rickets, and one of its earliest symptoms was constipation, in which there was a deficient tone to the bowel. The addition of cream to the food, cod-liver oil or kindred products would remedy this condition. After indiscriminate feeding, cream was added, hoping it would build up the baby. If the child was delicate, cream feeding was very apt to cause dyspepsia and greatly impair the digestive power. There must be a distinct indication for the need of fats and first they must diagnose the particular phase of malnutrition. By clinical and laboratory investigations they must determine the excess or insufficiency of one or more of the elements of food. Without this, he could conceive of no successful management. Having arrived at the particular form of malnutrition due to food disturbances, the management of the fats or proteins became one of individual prescription. Use could be made of a division of the milk products. The early months of infancy demanded a low protein percentage and by the use of whey in a modified milk, the same proportions of lactoalbumin and caseinogen as in human milk might be simulated.

**Symposium on Malaria.**—Dr. R. H. Von Esdorf of Mobile was directed in 1912 by the United States Public Health Service to make an investigation of the geographical distribution and prevalence of malaria in the state of Alabama. In July, 1913, the same work was extended to include the states of Arkansas, Mississippi, Georgia, South Carolina, North Carolina, and Florida. The campaign was one of education. Lectures had been given in schools and to the people to acquaint them with the exact facts in regard to the conditions prevailing in their own towns, particularly with regard to mosquito breeding places. In addition, he had lectured at universities and had taken high school classes and made surveys and taught these individuals how to identify the larvae from all other larvae, and they readily learned the differences and made surveys of their own. To save time he had advocated forming organizations, using boy scouts, and getting girls interested so as to make these surveys for local health officers. In connection with the intensive studies he gave an outline for studying the geographical and climatic conditions in each place; also the social, hygienic and economic conditions that prevailed in the particular places, the industries, and how they were affected and infected, so that the economic question was also being studied in this conservation, and estimations were being made from an economic standpoint in each one of the localities, so that undoubtedly it would prove of value when they got all of this information together to stimulate and arouse greater public interest and greater public demand for doing this work.

**Treatment and Cure of Malaria.**—Dr. C. C. Bass of New Orleans stated that perhaps the most perfect specific in medicine was quinine for malaria but like few other specifics it was a specific only when properly administered. The present paper dealt with the proper use of quinine in the treatment of malaria and gave fundamental facts and principles, based on experimental evidence and observation, which made such routine necessary. The asexual cycle of malaria plasmodia which caused the common symptoms of malaria in man took place partly in the blood stream and partly in the capillaries. The plasmodia lodged in the capillaries and remained until they segmented. The time spent lodged in the capillaries varied with the different species of plasmodia. The estivo-autumnal parasite, the most malignant of them all, remained lodged in the capillaries for at least thirty-six out of each forty-eight hour period or cycle. During the time the parasites were lodged in the capillaries they were beyond the reach and effect of quinine in the blood stream. Therefore, it was necessary to keep quinine in the blood for a period of at least forty-eight hours and preferably seventy-two hours or three days. The author stated that thirty grains of quinine on each of three consecutive days always destroyed all asexual plasmodia in the patient. There were no exceptions. Relapses resulted from reproduction in some manner not now well understood of sexual plasmodia or gametes which were usually present in variable number. They reproduced in seven days and multiples of seven days, and gave rise to the relapses occurring usually on the seventh, fourteenth, twenty-first, and sometimes twenty-eighth day. Gametes were not killed by quinine or any other drug but their products of reproduction were killed by quinine. Thirty grains of quinine once a week for six weeks would always sterilize the blood of all plasmodia after the asexual parasites had been destroyed by the first three days of quinine treatment. Continuous administration, especially of small doses of quinine, favored or increased the number of gametes and insured relapse or chronicity. The author laid down as routine treatment for malaria, from which there should seldom be variation, thirty grains of quinine during each of three consecutive days followed by thirty grains on the same day of the week on which the last of the three days fell for a period of six weeks.

**Malaria During the First Three Months of Life.**—Dr. B. H. Booth of Drew, Mississippi, outlined the usual treatment of malaria during this period as follows: cold baths to reduce the temperature, if practicable; if not, then hot ones. Small doses of heroin and atropin, or morphin and atropin to control the convulsions and equalize the circulation, not losing sight of the fact that young children, as a rule, bore morphine badly, hence it must be given very guardedly. As a good mercurial purgative, he preferred a mixture of calomel and the time honored mercury with chalk, followed by plenty of castor oil, as hot as could be given, also quinine which could be administered by mouth best in some syrup or the proprietary preparation euquinin, or used in the form of an inunction, the soluble salts dissolved in alcohol and glycerine, or as he thought the preferable mode by hypodermatic injections of quinine and urea salt, remembering that an infant at this age would bear well proportionately large doses of both the mercurials and quinines. The hypodermatic administration of the quinine was to be preferred to any of the others, as it was more prompt in its action, more sure in its results and was really easier on the child than either by the mouth or inunction, as it was administered in two doses, was comparatively painless, and allowed the child more rest besides being much less trouble to the attendants. After the acute symptoms had subsided, iron in such forms as to be easily assimilated with essence of pepsin, in appropriate doses, would cause a quick recovery from the emaciated condition.

**Some Observation on Mumps, with Discussion of Complications.**—Dr. J. S. Tuberville of Century, Florida, took the position that mumps was a more serious disease than is generally supposed, and that it could be contracted from persons through eating and drinking utensils before there was evidence of the malady. The idea that old people did not have mumps was a popular fallacy among medical men and perhaps had its origin in unrecognized cases earlier in life. There was a report of acute pancreatitis as a complication and a suggestion that this condition was more frequent than was generally thought. Further, that a certain number of chronic cases of pancreatitis perhaps had their origin from cases of mumps.

**The Medicinal Treatment of Bronchitis and Pneumonia.**—Dr. I. L. Van Zandt of Fort Worth, Texas, summed up his treatment of pneumonia and bronchitis as follows: Give a creosote preparation freely from the beginning in all cases. Use collargolum in all cases of small children, preferably by inunction. There might be some who did not need it, but it would do no harm. In cases of older persons, where there was a suspicion of an infection other than of pneumococcus, use it also. Do not understand that he never used anything but these specifics. Most frequently he did not, but kept a constant watch as to the necessity for anodynes, stimulants, etc., and used them when he deemed them necessary. Mention had been made in this paper of the use of antistreptococcus serum with apparent good results. The general reports of serum in pneumonia had not been encouraging, not at all to be compared with its use in diphtheria and meningitis. The reason of this was that in each case of these two diseases, they had a single specific microorganism to contend with, while not infrequently in pulmonary infection, the organisms were multiple and various.

**Pellagra.**—Dr. Seale Harris of Mobile, Ala., stated the published death rates for pellagra were too high and gave no idea of its prevalence. After considering the digestive symptoms, and the importance of early diagnosis, he stated that in beginning the treatment of pellagra he usually gave several small doses of calomel, 1/20 grain every hour until ¼ grain was given, then bismuth subnitrate in from ½ to one dram doses with five grains of salol every 2 to 4 hours as might be necessary to control diarrhea. He had rarely found it necessary to use opium.

Where there was absence or deficiency of hydrochloric acid, dilute hydrochloric acid with pepsin often relieved the gastric symptoms and would not infrequently control diarrhea. Colonic irrigation with normal salt solution was often helpful, and in some cases, where there was pain in the rectum anesthesin suppositories gave great relief. When there was stomatitis with ptyalism the chlorate of potash given internally yielded splendid results. Mild antiseptic mouth washes, as diluted liquor antisepticus alkalinus were helpful. Lombroso thought that arsenic and the chloride of sodium were antidotes for the toxines from spoiled corn and following his teachings the author had used both in large doses. The salt was usually mixed with the food. Fowler's solution of arsenic was the best preparation and should be given in ascending doses of from 1 to 15, or even twenty drops three times a day, or until the physiological effects were obtained. He had used a toxyl in a number of cases, but had not been pleased with the results. Salvarsan had also been used with varying results by different observers. He was inclined to think that the arsenic must be taken into the alimentary canal to get the beneficial results. He had seen very remarkable improvement in the digestion and general nutrition of patients with pellagra follow the use of Fowler's solution. There was no disease or condition with which he was familiar in which the confidence of the patient was more important than in pellagra.

**Pathology of the Heart in Rheumatic Infection in Children.**—Dr. W. W. Harper of Selma, Ala., showed slides of ten cases, and a study of them demonstrated (1) that in children endocarditis was often the only symptom of rheumatism. (2) That chorea was the result of a rheumatic infection, and that every child suffering from acute chorea should be placed in bed and kept there until the acute symptoms had subsided. (3) That a primary attack of rheumatic endocarditis was not ulcerative. (4) That a first attack of rheumatic endocarditis usually left the heart valves in such a condition that vegetations frequently developed during a second attack of rheumatism. (5) That such valves were peculiarly vulnerable should the patient be subsequently attacked by any of the pus-producing bacteria, such as the pneumococcus, streptococcus or colon bacillus.

**Central Cirrhosis of the Liver.**—Dr. V. H. Bassett of Savannah, Georgia, reported a case of central cirrhosis of the liver with acute endocarditis of gonorrheal origin in a young man 22 years of age, following an acute attack of acute specific urethritis. The clinical features of the case were fever with delirium, dyspnea, hemoptysis, and icterus, and moderate generalized edema. The course of the disease was about 8 weeks. At autopsy an acute ulcerative and vegetative endocarditis of the mitral valve, with a stemosis, was found, with hypertrophy and dilation of the right side of the heart. The lungs showed the changes of chronic passive congestion. The liver did not resemble a nutmeg liver, but differed from a normal liver only in being somewhat cloudy, paler, and somewhat firmer in consistency. The condition of fibrosis of the centers of the lobules was not suspected from the anatomic condition, but was found on making microscopic sections of the liver. The fibrosis was diffuse, affecting the centers of practically all the lobules, and occupied a space of a round or oval character, about equal in width to ¼ of the radius of the lobule. The connective tissue was young connective tissue and there was little pigmentation or other evidence of a previous chronic passive congestion of any extent. Dr. Bassett reviewed the work of Mallory, Opie and other investigators on the localization of necroses and Krotz in regard to the pathogenesis of fibrosis from localized or focal necroses. He cited a suggestion of Mallory that in some cases the fibrosis of central cirrhosis proceeded not from the stasis in the liver, except as an accessory factor, but from the necroses which had resulted from the attending infection, and offered his own case as a possible example. He suggested an anatomic classification of the cirrhosis of the liver based upon the localization of the fibrosis or of the necroses preceding it, in the vascular lobule, and considered the advantages and disadvantages of such a classification, acknowledging that it was difficult to place all types of clinical cirrhosis in the classification, but stating that similar difficulties were encountered in any system of classification. He reviewed the opinions of the older and more recent writers on cirrhosis of central origin with Piery and others that fibrosis rarely occurred as a distinct type of cirrhosis in the congested liver, and that there was no evidence that atrophic cirrhosis arose from this cause. He suggested that a central cirrhosis might occur which did not depend on congestion as a casual agent, but this type was rarely observed.

**Some Views on the Etiology of Pellagra, Based Upon the Experimental Inoculation of Monkeys and Rabbits.** Dr. W. A. Dearman of Long Beach, Mississippi, was prompted and led to make investigations along the line of insect transmission by the marked seasonal spring incidence of pellagra, the rise and fall of pellagra and malaria in his section along the Gulf Coast. The first of his activities in this direction was with the bedbug. He was successful in collecting from a bed, which a pellagrin had occupied for six months, a large number of these human parasites, including about fifty large and small; these were kept in a wide-mouthed, well veltilated jar. He induced these bedbugs to bite and abstract blood from the large vein underneath the wing of a full grown chicken. It was necessary to extinguish the light before they would begin their activities in sucking blood; after a few minutes they were removed to a test tube and there could be seen several discrete ecchymotic spots on the skin overlying the vein where they had been active in abstracting blood. This process was repeated at intervals of every other day for about three weeks; a greater number of the bugs, by this time, were dead, due to their deadly combat. Up to this time, a period of about four months, no lesions had developed in this chicken. On several occasions, his attention was attracted by the malignancy of certain cases of pallagra, as well as other members of the same household suffering from the disease, or in individuals who had frequently visited these homes, in which homes and on whose premises, there were found mangy dogs, heavily infested with fleas, (*Tcenocephalus serraticeps*) which dogs were in the habit of sleeping on the beds in the day time. One of these patients, a negro woman, gave a history of having been heavily infested with fleas from this dog, and had noticed no signs of her pellagrous condition until she had become in possession of the dog. He bought the dog and immediately placed him in a cage with a full grown Rhesus monkey, and kept them continuously associated for thirty-seven days. The monkey soon became heavily infested with fleas from this dog, as they could be seen crawling on her body and buried in the skin. The dog soon died from emaciation and a black diarrhea. Up to this time, a period of three months, no signs of pellagra had developed in the monkey. Plague, under the name of black death, which once decimated the populations of the earth, having made its grewsome appearance first on our shores in coast cities and towns, and being principally transmitted by the rat flea, induced him to investigate this insect as a probable transmitter of pellagra. Furthermore, pellagra was principally a European disease, and coming to our shores in exactly the same manner, first making its appearance, according to statistical records, on the coast of the Carolinas, and later invading new territory in the interior with alarming rapidity and unabated. Samples of cornmeal were obtained from pellagrous homes and from local dealers. Moulds were cultivated, isolated aerobically and anerobically, suspended in physiological salt solution, and experimentally injected and fed to rabbits, chickens, pigs and monkeys. Neither ever developed any lesions resembling pellagra. From what he had gained in the way of experimental inoculations with blood of pellagrins in the incipiency of the disease, and the report of Everett S. Lain's investigations on skin diseases among full blood Indians of Oklahoma (*Journal A. M. A.*, July 19, 1913, Vol. LXI, p. 168), with other evidence too numerous to set forth in this article, he felt inclined from his own observations and from Lain's statement of the study of these five thousand Indians to find a single case of pellagra, while they subsisted principally on spoiled corn, to doubt very materially that the cause of the disease was lurking in spoiled corn; that the condition known as pellagra, which was becoming so alarmingly prevalent in the southern states, invading new territory, leaving death, insanity and invalidism in its wake, terrorizing our American people and yielding to no therapeutic applications, was to his mind, without evidence at hand, a disease that in all probability was an insect-borne disease, and the dog and cat flea should be looked upon with suspicion, not to the exclusion of other possible transmitters, and further experiment, study and observation were yet lacking and needed to discover to come into full possession of all the facts relating to its etiology.

**Cocaine as a Respiratory Stimulant.**—Dr. George E. Pettey of Memphis, reported two cases showing the effect of cocaine. The first was one of chronic alcoholism with threatened respiratory failure, respiration irregular, 5 to 10 per minute. After several hours' effort at restoration by administration of caffeine, strychnine, adrenalin, ilynological salt solution, etc., without improvement, ½ gr. cocaine was given and repeated in 30 minutes. Slight improvement followed the first dose, and in 10 minutes from sec-

ond dose, respiration was 12 and regular. This improvement lasted one and one-half-hours, but at the end of ½ hour more, respiration was 8 to 9 per minute; ¾ gr. cocaine then given raised the rate to 12 again. This rate was maintained two hours, and both decrease in rate and irregularity occurred. One gr. cocaine then given restored rate to 12 to 14 per minute. In this case, in order to keep respiration up to a satisfactory rate, one gr. cocaine was required about every three hours for five days, during which time thorough elimination removed toxins from the system and the drug was no longer needed. Attempts to substitute other respiratory stimulants for it were unsuccessful.

The second case was one of paraldehyde poisoning. Patient had taken ½ oz. paraldehyde at 9 A. M., and sleep not following, another ½ oz. was taken at 1 P. M. At 2 P. M. he was found in a profound stupor from which he could not be aroused. He was cyanotic, breathing 6 to 8 per minute, pulse 120. Vigorous efforts to arouse him from stupor including dilation of anal sphincter were unavailing. Strychnine, adrenalin, and faradic current to base of brain made no perceptible impression. Artificial respiration was then resorted to and was being used when he saw the case, one hour from time active efforts at restoration were begun, and two hours from time of taking last paraldehyde. At this time, upon stopping artificial respiration for short time, 3 or 4 voluntary respiratory efforts per minute occurred; pulse 150; patient deeply cyanotic; ½ gr. cocaine was given, and repeated in 15 minutes, and 30 minutes later one grain was given. Artificial respiration continued and patient's body enveloped in blankets wrung out of hot water. More vigor in the few voluntary efforts at respiration were noted five minutes after second dose of cocaine was given, and 10 minutes after third dose, 6 to 8 voluntary efforts at respiration per minute occurred, and they were able to suspend artificial respiration 5 to 10 minutes at a time. Thirty minutes later from time of giving the 1 gr. dose of cocaine, another of that size was given, and within 10 minutes from that time, breathing was 8 to 10 per minute, and fairly regular. This condition continued 40 minutes, when respiration again became irregular and slow. One gr. cocaine was then given, with prompt increase of respiration to 10 or 12 per minute, after which no further restoratives were necessary. Notwithstanding the unfavorable results reported from the effects of cocaine, he believed, after a rather extended experience, that the remedy could be used with safety when a respiratory stimulant was really indicated, and especially so in opium and other forms of drug narcosis.

**Abderhalden Test.**—Dr. William Krauss of Memphis said that the causes of failure might be enumerated as follows: (1) Due to the serum. It must be fresh, uncontaminated, secured after a fast of eight hours to eliminate the products of digestion, and pale almost to colorlessness. It must be obtained through a dry sterile needle "sheer" into a dry, sterile centrifuge tube and immediately centrifugalized, and the serum not pipetted off if the test was made within a few hours. The serum must not be opaque. (2) Due to the placenta. It was now directed that the placenta be chopped up and entirely freed of blood immediately after it had been "Creded." This required some hours. The pieces were thrown into boiling water containing a few drops of acetic acid, boiled five minutes, expressed, boiled again in a smaller amount of acidified water, and this tested in the ninhydrin, and, if positive, boiled again. He then advised percolation with distilled water, incubation with normal serum, further percolation, reboiling, and percolation. Before each test boiled and percolated again. (3) Due to faulty dialyzing thimbles. Even the "No. 579 a" thimbles must be rigidly tested. After a test they must be passed through many changes of distilled water. Some tap waters might clog them, also bacterial growth, and rough handling might make them leak. (4) Due to old or improperly stored ninhydrin solution. It should be fresh, of exact strength and stored in amber bottles. (5) Due to faulty technic. The outside of the thimbles must be rigidly guarded from contamination by placenta or serum. The immersion must be to the exact prescribed depth and the proper distance between the thimble and wall of the outer cylinder preserved. Dr. Krauss used a system consisting of a test tube open at the bottom upon which the thimble was slipped. Near the top was a vent hole to establish equal air pressure within and without the tube. The test tube passed through a perforated rubber stopper through which it could be lowered to the desired depth. A pledget of cotton saturated with chloroform was put into the mouth of the test tube and a cork over that. Incubation could then be done in a basterial incubator without chloroforming any cultures that were in the incubator. He preferred Schwartz's plan of boiling 5 c.c. of the dialyzate with 0.1 c.c. ninhydrin. He used a marked wide test tube and restored the bulk after boiling for one minute. There had been no failure either way in the two tests made since adopting his latest technic, but he expected to meet them with more experience. He thought inactivated serum was the best control.

**Symposium on Tuberculosis.**—Dr. E. C. Thrash of Atlanta, Georgia, attempted to show that tuberculosis was as certainly an alimentary disease primarily as was typhoid fever. His experience in handling large numbers of children of tuberculous parents had been that practically all of them had tubercular adenitis, and were positive to the Moro and Von Pirquet test, showing that they had become infected from their parents, but he rarely found one with lung involvement. Also most of the children which he had examined post-mortem at the Grady hospital that had died of chronic, wasting diseases due to disturbances of nutrition, had shown tubercular infections in the lymphatic glands of the abdomen with normal lungs.

**Distinction Between an Infection by Tubercle Bacilli and Tuberculosis.**—Dr. Mary E. Lapham of Highlands, North Carolina, stated that tuberculosis entered every home. All children were infected before maturity. It was impossible to avoid the infection. Children should be examined by experts in order to detect the first changes before harm had been done. They should not allow children to become victims before they knew it. Tuberculosis in well people was the most dangerous because it was never suspected. Good health and tuberculosis were perfectly compatible. All animals had tuberculosis because the bacilli were universally present in their food. Four hundred thousand children in the United States were infected with tubercle bacilli from the milk of cows. It was not enough to protect a child from exposure to contagion. The insidious development of an ever present infection demanded detection by regular examinations. They should not wait until the horse was stolen before they locked the barn door. They should remember the relation of the universal presence of acid fast bacilli to the universal tuberculosis of animals. The relation of the etiology of tuberculosis to an intestinal infection was as common as that by the colon bacilli. The infection by tubercle bacilli was not prevented by quarantine or segregation. The development of this inevitable infection must be arrested by its prompt detection. This could only be assured by regular examinations by competent experts. The prevention of tuberculosis could never be accomplished by obliteration. Detection and no delayed diagnoses were their surest safeguards. A scientist should be employed to teach the people the comprehension of the truths concerning tuberculosis.

**Protection for the Post-Sanatorium Tuberculous Patient.**—Dr. L. B. Morse of Hendersonville, N. C., in his paper, set forth some general rules for the guidance of ex-sanatorium patients; (1) Place yourself under the care of a good physician. (2) Approximate the sanatorium life closely, particularly in the beginning. (3) Rest in bed for one week. (4) Increase exercise (walking) with exceeding care both as to time and distance, and note results. (5) Take the precaution to "rest before getting tired." (6) Make regular hours a conscientious habit, both as to rest, exercise, meals and sleep. (7) Keep away from every sort of place of amusement and entertainment until thoroughly cured. (8) Reduce visiting to a minimum. (9) Maintain, if possible, a good body weight. (10) Be scrupulously particular regarding the morning bowel movement. (11) With increasing strength, exercise an increasing pride in the maintenance of a good bodily posture. (12) Taboo all dissipation. (13) Protect the patient, if possible, from all worry and strain. (14) Do not remain in the same room with a patient suffering from any sort of acute inflammation of the nose or throat. (15) Finally, remember always that the things that made you well, in the main, were the things that would keep you well.

**Diagnosis and Treatment of Tuberculosis.**—Dr. Dunning S. Wilson of Louisville said that the essentials were, first, prompt diagnosis: secondly, cooperation of the patients: thirdly, institutional training, and, fourthly, continuation of the treatment at home, bearing in mind that even the earliest cases of tuberculosis were not permanently benefited in less than a year of prescribed routine. Certain improvement and basic parts of the routine must become fixed habits of life if a relapse was to be prevented.

**The Value of Rest, Physical and Mental, in Tuberculosis.**—Dr. Wallace J. Durel of New Orleans stated that the purpose of this paper was to show, though they

could derive some beneficial effects by the use of exercise, absolute rest must replace the latter in active tuberculosis, and modified rest in quiescent and arrested tuberculosis. They knew that exercise entertained the formation (to excess) of tuberculin protein poisons; and that the effects of the latter (in excess) upon the body cells of the human organism were deleterious to the improvement of the tuberculosis patient. The effects of exercise upon the leucocytes, especially the neutrophiles, partly accounted for the harm done by exercise. Rest was essential in the active incipient tuberculosis, during the first weeks or months of treatment. Rest was absolutely essential in all cases of febrile tuberculosis. Definite written orders, specifying rest in the reclining posture, and at definite periods, was essential for good results in all forms of tuberculosis. In quiescent and active tuberculosis, the physician must be positive in his assertions, and must not allow himself to be influenced by sympathy or antagonism; and thus permit his patient to cease the carrying out of the prescribed rest. The loss of weight, temperature, acceleration of the pulse, disturbance of digestion, and the neutrophile index, were the only means for determining when a patient must return to absolute rest, after the taking up of exercise. The practice of keeping patients in sanatoriums for a specified time of three months, was not of much benefit to the poor tuberculosis patient. That the recovering tuberculosis patient must be prepared and trained by varieties of exercise, in order that he might resume his previous work, was more theoretical than practical. It was not a question of preparing the tuberculosis patient for his work or occupation; but one of ridding him of his tuberculosis, and of his incapacity for work, and of the danger of infection to his fellow men. The "farm" and "autoinoculative" plans of providing for the quiescent tuberculous had not proven of greater value than those measures where rest was the prime factor and exercise the secondary factor. The psychic or mental condition of the tuberculous patient must be carefully studied. Worry and uneasiness must always be alleviated.

**Some Phases of the Tuberculosis Problem.**—Dr. W. R. KIRK of Hendersonville, N. C., maintained that the tuberculosis problem was primarily a medical one, but the social side, which struck the marrow of the question in the maintenance of life itself, could not be ignored. Any controversy as to their relative importance was a waste of time and energy, but a combination of all the combative forces would be necessary to overcome the greatest menace to human life. He would urge a thorough comprehensive and cooperative union, working upon the unit system, of all the forces in the field, medical, social, economic, and administrative. The tuberculosis problem differed somewhat in each section of the country. The South did not suffer from crowded tenements, sweat shops, and foreign elements of population as in other sections, but they had the negro. He thought tuberculosis was slowly solving the negro question in the South with its frightful mortality to that race, but it was also a constant source of danger to the whites. This phase of the problem was put up to the State Board of Health and in this connection he deplored the lack of interest and cooperation in the medical profession in the work of the public health board, and suggested the appointment of a committee for closer cooperation with those boards in an advisory rather than administrative capacity. They, as physicians, should teach the masses how to protect themselves against tuberculosis. The facts must be presented in a startling manner, but he believed they had overshot the mark, and that it was now time to allay some of the unreasonable fear by more rational teaching. He thought that the tuberculosis exhibit scared more people than it instructed. A wholesome dread of the infection was to be desired, but an insane fear did harm to the cause. He also questioned the wisdom of excluding tuberculosis patients from the general hospitals, for besides increasing this fear of contagion among the people, it seemed to be working to the disadvantage of the medical man by limiting his opportunities for study of the disease at the bedside in the hospitals and medical schools. He would criticise the increasing tendency of the profession to send tuberculosis patients away from home, not for specific treatment but to build up by their own unaided efforts. Under the noncommittal diagnosis of neurasthenia they were sent out in various stages of the disease to mingle among the healthy people, incapable of properly managing their own cases, the true nature of which they were trying to conceal. He regarded this practice as an injustice both to the patient and to society at large.

**Pulmonary Embolism as a Surgical Complication.**—Dr. JOHN H. BLACKBURN of Bowling Green, Kentucky, stated that pulmonary embolism secondary to venous thrombosis was a relatively frequent complication in general surgical and puerperal cases as well as after operations. There was no specific cause in all cases, but as a rule, it developed as the result of a combination of trauma and certain blood changes, either of a chemical nature or from bacterial invasion. A vast amount of experimental work had been done to prove or disprove certain theories regarding thrombosis and embolism, but the solution of cause and prevention would depend upon the carefully kept and reported records of clinical cases, that the relationship of the many factors might be learned and the predisposing causes removed. Even with the most careful preparation, operative procedures and after-treatment there would doubtless be a certain number of cases of thrombosis with the secondary development of embolism.

**The Treatment of the Pus Appendix.**—Dr. GEORGE H. BUNCH of Columbia, N. C., said by not just draining the abscess, but by removing the appendix, which was the pathology of the condition, by closing the incision and draining through a stab-wound, thus obviating the necessity of a secondary appendectomy, Guerry, so far as short convalescence and permanent cure were concerned, made the pus cases in effect clean cases. With all this he accomplished a lower mortality than was reported by those practising other methods.

**The Relation of the Medical Profession to Accident Insurance.**—Dr. EDWARD MAGRUDER of Baltimore said that it was incumbent upon them to see that their interests as policy holders were properly protected. They could assist in bringing about this result in the following ways: 1. By using their influence to the end that the companies operating in their several States were properly supervised, not unjustly taxed, were carefully administered and were honestly represented. 2. By endeavoring to prevent fraudulent claims or imposition upon insurance companies through the ignorance of the true conditions or cupidity on the part of their patients who were policy holders, they could assist in reducing the number of unintended losses to accident companies, and, as a result, enable them to sell insurance protection at a much smaller cost. 3. It was their duty to themselves and their families to immediately inspect their own policies and determine whether the statements in their part of the contract were true and the policy therefore, valid, or whether through carelessness or delegation of the matter to local insurance agents, their applications contained incorrect statements which might reduce the value of, or render absolutely worthless, their own insurance policies.

**Congenital Pyloric Stenosis.**—Dr. LYLE S. BOOKER of Durham, N. C., stated that the two indications for surgical treatment were: First, to meet the emergency of starvation by overcoming the obstruction at the pylorus. Second, to restore the continuity of the alimentary tract so that it might serve the individual through life. The best operation to meet the demands was the posterior gastroenterostomy. The following were his conclusions: (1) The pathogenesis of this condition was unsettled. (2) The diagnosis was usually not difficult. (3) The indications for surgical treatment were common-sense ones. (4) The operation best suited to this condition was the posterior gastroenterostomy. It was ideal in that nature had prevented the possibility of a vicious circle by obstructing the pylorus. (5) The operative mortality was low.

**Gallstones Complicating Pregnancy and the Puerperium.**—Dr. JOSEPH GRAHAM of Durham, N. C., reported six cases of gallstones complicating pregnancy.

**The Surgical Treatment of Goiter.**—Dr. JOHN R. WATHEN of Louisville stated that his own experience, which included over three hundred operative cases of goiter covering a period of the last eight years, furnished the data for his paper. Those operations embraced two general classes, the simple and the exophthalmic types, in numbers about equally divided. A proper time to advise operation with the expectation of mortality and good results was after the thyroid enlargement had begun to manifest the early symptoms of exophthalmic goiter, and had existed for several months with little or no signs of improvement. In the selection of their patient for operation they should realize that early operation, before complications had arisen as in appendicitis, gallstones, etc., offered the best results. All the patients operated upon by him, and who left the hospital as cured, had remained as cured or greatly benefited, the latter class being the cases seen late in the progress of the disease. His mortality had not been much over 4 per cent., and he had benefited all upon whom he had operated, apparently cured permanently about three-fourths and the remainder of-

fered relief to some extent. He believed we had now almost completely mastered the greatest drawbacks to goiter operations, *i.e.* the injury to the recurrent laryngeal nerve and the resultant paralysis of the voice, either complete or partial paralysis.

**The Evolution of the Treatment of Ectopic Pregnancy.**—Dr. STUART MCGUIRE of Richmond, Va., said that all surgeons were agreed that an operation should be done on a case of unruptured tubal pregnancy as soon as the diagnosis was made. Instances were so numerous of rupture occurring while the patient was waiting to go to the hospital, or while in the hospital, waiting for the surgeon to come, that it was now the universal practice to operate upon these cases with the greatest promptness. There was a serious difference of opinion among the best surgeons as to when to operate on a case after rupture occurred. Personally, he favored an immediate operation not only because it was in accord with general surgical principles, but also because in personal experience he had seen the practice save apparently moribund patients. He was opposed to the removal of the opposite tube, unless it was clearly, hopelessly diseased. If by leaving it he had subjected some patient to a second operation that might have been avoided, he had equally certainly made possible the birth of some babies that otherwise would not have come into existence.

**Growths and Syndromes of the Thyroid Gland Requiring Operation.**—Dr. WILLIAM D. HAGGARD of Nashville, Tennessee, stated that one of his most striking cases was in a woman, aged 36 years, acutely ill for ten weeks, with severe vomiting and diarrhea, with a loss of 59 pounds. The pulse varied from 160° to 180°, and she was so nervous and weak that transportation all but resulted in death. A ligation of first one and then the other superior thyroid artery very promptly resulted in great improvement, with a gain of 70 pounds in ninety days. In this case there was scarcely any perceptible enlargement of the thyroid, and he had not advised removal of one lobe. The acute exacerbation should be the *noli me tangere* of the surgeon. If undertaken when the disease was at its height fatal intoxication would often ensue within 36 hours. The same might be said of the very far advanced cases with cardiac insufficiency, ascites, etc. Careful medical management might restore some of those cases to a condition where surgery could benefit. As Crile said, "In any case the operation is but a means to the end. The raising of the threshold of environmental stimuli by diminishing the amount of activating sensitizing thyroid secretion and in conjunction with physical and psychic rest, permitting the patient to regain the power of normal control by the brain. Travel, diversion, nature, all are helpful, the operation serving to break the pathological change at one of its strongest links. These patients should be and can be literally taken by the hand and led away from mankind through the flowery paths of ease and pleasure to the haven of health.

**Ovariotomy Subpartus.**—Dr. W. KOHLMAN of New Orleans, stated that the important points in the treatment of those complications were: (1) Vaginal ovariotomy in small tumors without adhesions was to be followed by delivery by the natural passages. (2) Cesarean section and abdominal ovariotomy should be the operation of choice in all cases of solid tumors, cystic tumors, with probable adhesions, or intraligamentous development, or in all conditions where a prolonged and difficult labor was suspected.

**Observations on Anxiety-Neurosis.**—Dr. S. T. RUCKER of Memphis said that as a general predisposing cause of anxiety-neurosis heredity played a large part. Neuropathic parents transmitted to their children a delicately poised and sensitive organization. They were emotional, mobile, and unstable. They reacted abnormally to irritating and depressing influences and were potentialized towards nervous diseases. His observation had been that hereditary taint came most frequently from the mother. Not infrequently a neuropathic mother would transmit a similar condition to all her children. In one family whom he had under observation and treatment, the father was tuberculous all of his married life and finally died of tuberculosis, leaving three children. Ten years after his death the wife had a severe attack of melancholia, but recovered and had since been well. Two of the children had nervous breakdowns, and the other one was psychically abnormal. In another one of his families the mother suffered from hysteria ten years, was treated and recovered. She had two children; one was treated for neurasthenia and the other one for psychasthenia. The father of these children was a normal, healthy man. Another predisposing cause of anxiety neurosis was early education in the home. Indulgent parents often failed to teach their children self-denial and self-control. A child grew up to girlhood accustomed to every whim being gratified and an abundant sympathy being lavished on every woe, however trifling. She reached womanhood with a mental organization unfitted to withstand the cares of every day life. She weakened under the strain of trying ordeals and developed a nervous trouble. The symptom complex of anxiety neurosis was often associated with neurasthenia, hysteria, psychasthenia, and melancholia, and formed a clinical picture around which the classic symptoms of these diseases were grouped. By the process of suggestion and reeducation wrong beliefs and habits of thought could be changed or repressed and healthy psychic complexes be organized and substituted for unhealthy ones.

**The Cancer Problem.**—Dr. W. A. BRYAN of Nashville, Tennessee, stated that there was a more or less prevalent opinion among the people that cancer was fundamentally a general disease, "a blood disease," as they were pleased to term it, and that, therefore, no matter how extensive local treatment might be applied, it could do no good. It was true that many cancers did become disseminated through the body by the blood or otherwise at a certain stage of their development, and that then the case was hopeless, but the condition was never general from the beginning. On the contrary, cancer was just as much localized at the beginning as a mole or a wart or a pimple. From this small and curable beginning it gradually invaded the surrounding structures and became less easily curable until it passed certain limits in a local way or invaded the remote parts of the body and had positively become incurable. It was important to impress here that the time division between a curable and an incurable cancer might be no longer than a single pulse beat. A bruise, a cut, rough handling of the tumor by patient or surgeon might loosen the cancer cells into the circulating blood and render hopeless the curable case of a moment ago. The value of this could be seen in a practical way, for if the curable became incurable in the twinkling of an eye, and if the time of such occurrence was uncertain, no time should be lost in determining the nature of the malady and having settled this point, no delay should be countenanced by the physician or patient until the growth was destroyed.

**Officers.**—The following officers were elected for the ensuing year: *President,* Dr. Stuart McGuire, Richmond, Virginia; *First Vice-President,* Dr. J. W. Jervey, Greenville, South Carolina; *Second Vice-President,* Dr. F. H. Clark, Lexington, Kentucky; *Secretary-Treasurer,* Dr. Seale Harris, Mobile, Alabama.

Richmond, Virginia, was selected as the place for holding the next meeting.

---

**Action for Compensation.**—The decision in a recent action for compensation may be set out in the language of the court: "This was a contest between two members of the gentler sex. The plaintiff was a practitioner of the art or science of osteopathy, and the defendant either needed, or thought she did (which is the same thing) the services of the plaintiff. Several visits were made at $3.10 per visit; the 10 cents being added for street car fare, and the whole bill amounted to $27.90. The defendant says she paid all she really owed, and that the plaintiff charged her for a number of social calls, during the course of which the defendant was importuned to continue the treatment. The defendant says that she declined to do so, and that the services rendered by the doctor gave her no relief, and were so unsatisfactory that she was forced to resort to a physician of the allopathic school, who administered pills and mixtures in the good old-fashioned way. On the issues of fact the plaintiff outswore the defendant, or at least the jury in the justice's court thought she did, and the judge of the superior court refused to interfere. This is the end of the law so far as this branch of the case is concerned. It would never do to hold that a doctor is entitled to recover only when he cures the patient. If we did, the members of this learned profession might hesitate to respond in extreme cases where the chances were against them. So far as we are concerned, the doctors may continue to bury their mistakes and recover for their services as they have always done. If we were dealing with lawyers, the rule might be different; but sufficient unto the day is the evil thereof. The defendant says that she ought not to pay the extra 10 cents per visit because the doctor usually walked. However, the plaintiff testified that the charge was usual and reasonable. If so, she had a right to walk and save the 10 cents."—Hall v. Mooring, Georgia Court of Appeals, 76 S. E. 759.

## Books Received.

*The* MEDICAL RECORD *is pleased to receive all new publications which may be sent to it, and an acknowledgment will promptly be made of their receipt under this heading; but this is with the distinct understanding that it is under no obligation to notice or review any publication received by it which in the judgment of its editor will not be of interest to its readers.*

MODERN MEDICINE. Its Theory and Practice. Edited by Sir WILLIAM OSLER, Bart., M.D., F.R.S., and THOMAS McCRAE, M.D. Vol. I. Illustrated; cloth; 1093 pages. Lea & Febiger, Philadelphia and New York.

CANCER OF THE BREAST. An Experience of a Series of Operations and Their Results. By CHARLES BARRETT LOCKWOOD, F.R.C.S. Cloth; illustrated; 234 pages; price $3.00. Oxford University Press, New York.

A TEXTBOOK ON GONORRHŒA AND ITS COMPLICATIONS. By Dr. GEORGES LUYS. Translated and Edited by ARTHUR FOERSTER, M.C.R.S., L.R.C.P. Illustrated; cloth; price $4.50 net; 384 pages. William Wood and Company, New York.

EARLY PULMONARY TUBERCULOSIS. By JOHN B. HAWES, 2ND, M.D. With Preface by RICHARD C. CABOT, M.D. Cloth; price $1.50 net; illustrated; 114 pages. William Wood and Company, New York.

EPIDEMIC INFANTILE PARALYSIS. By Professor PAUL H. RÖMER. Translated by H. RIDLEY PRENTICE, M.B., B.S., M.R.C.P.; illustrated; cloth; price $2.75 net; 208 pages. William Wood and Company, New York.

THE HUMAN BODY AND ITS ENEMIES. By CARL HARTMAN, B.A., M.A., and LEWIS BRADLEY BIBB, B.A., M.D. Illustrated; cloth; price 84 cents; 358 pages. World Book Company, New York.

DIE SRÖRUNGEN DER MÄNNLICHEN GESCHLECHTSFUNKTIONEN UND IHRE BEHANDLUNG. By Dr. EMIL KANTOROWIEZ, Illustrated; cloth; 118 pages. Urban and Schwarzenberg, Berlin and Wien.

TASCHENBUCH DER DIAGNOSTIK UND THERAPIE DER LUNGENTUBERKULOSE. By Dr. HEINRICH GERHARTZ. Illustrated; cloth; 200 pages. Urban and Schwarzenberg, Berlin and Wien.

LEITFADEN DER ERSTEN HILFE. Ein Samariterbuch. By Dr. J. LAMBERG. Illustrated; cloth; price 5 Mks.; 275 pages. Urban and Schwarzenberg, Berlin and Wien.

PATHOLOGISCH-ANATOMISCHES PRAKTIKUM FÜR STUDIERENDE UND ÄRZTE. By Prof. Dr. Med. RICHARD OESTREICH. Cloth; 304 pages. Urban and Schwarzenberg, Berlin and Wien.

TASCHENBUCH DER MAGEN- UND DARMKRANKHEITEN. By Dr. WALTER WOLFF. Illustrated; cloth; 163 pages. Urban and Schwarzenberg, Berlin and Wien.

ARTIFICIAL PARTHENOGENESIS AND FERTILIZATION. By JACQUES LOEB. Cloth; price $2.50 net; illustrated; 312 pages. The University of Chicago Press, Chicago, Illinois.

BERIBERI. By EDWARD B. VEDDER, A.M., M.D. Illustrated; cloth; price, $4.00 net; 427 pages. William Wood & Company, New York.

SPÄTYPSYCHOSEN KATATONER ART. Eine Klinische Studie. By Dr. Med. MAURYCY URSTEIN. Paper; 440 pages. Urban and Schwarzenberg, Berlin and Wien.

INNERE SEKRETION. Ihre Physiologischen Grundlagen und Ihre Bedeutung für die Pathologie. By Prof. Dr. ARTUR BIEDL. Paper; illustrated; 692 pages; price 24 Mks. Urban and Schwarzenberg, Berlin and Wien.

DIAGNOSE UND THERAPIE DER HERZKRANKHEITEN. By Prof. Dr. LUDWIG BRAUN. Paper; illustrated; 362 pages. Urban and Schwarzenberg, Berlin and Wien.

DIE MALARIA NACH DEN NEUESTEN FORSCHUNGEN. By Prof. Dr. ANGELO CELLI. Paper; price 16 Mks.; illustrated; 294 pages. Urban and Schwarzenberg, Berlin and Wien.

UBER DIE PATHOGENES DER SALVARSANTODESFÄLLE. By Dr. WILHELM WECHSELMANN. Paper; illustrated; 84 pages. Urban and Schwarzenberg, Berlin and Wien.

HANDBUCH DER SPEZIELLEN PATHOLOGIE DES HARNS. By Dr. Med. FERDINAND BLUMENTHAL. Paper; 492 pages. Urban and Schwarzenberg, Berlin and Wien.

KRANKHEITEN DER NASE UND MUNDHÖHLE SOWIE DES RACHENS UND DES KEHLKOPFES. By Dr. ALFRED BRUCK. Paper; 472 pages; illustrated. Urban and Schwarzenberg, Berlin and Wien.

RONTGENTIEFENTHERAPIE. By Prof. Dr. C. J. GAUR and Dr. H. LEMBEKE. Paper; illustrated; 332 pages. Urban and Schwarzenberg, Berlin and Wien.

DIE AMBULANTE THERAPIE DER LUNGENTUBERKULOSE und Ihre haufigsten Komplikationen. By Dr. KARL BLUMEL. Paper; 208 pages. Urban and Schwarzenberg, Berlin and Wien.

## Therapeutic Hints.

**Benzol in the Treatment of Leucemia.**—M. Brelet states that this drug may be given by the digestive tract or hypodermically. The latter method may be used in cases of intolerance on the part of the stomach, for the injections of benzol are very painful. The pain may be diminished by mixing the benzol with an equal quantity of olive oil. The dose to be injected is from 1.5 to 2 grams of benzol one or two times a day. Klein, who has observed poisoning result from the injection of the above dose twice a day, recommends its use only once daily. If internal administration is resorted to the drug should be given just before meals, to avoid the gastric irritation that may follow.

There is no unanimity of opinion as to the correct dose of benzol. Some authors recommend large doses given intermittently, while others advocate small doses long continued. The larger doses reach 4 and 5 grams per day. Kiralyfi prescribes gelatin or keratin-coated capsules containing the following:

℞ Benzol, chemically pure,
Olive oil, āā 0.5 gram.

In the beginning of the treatment two capsules are given twice daily, after the principal meals. The dose is increased until 3 to 5 grams of benzol are given daily. These large doses, while causing a rapid decrease in the leucocyte count sometimes give rise to albuminuria and hematuria.—*Gazette des Hôpitaux.*

**Transthoracic Intrapulmonary Injections in the Treatment of Pulmonary Tuberculosis.**—Georges Rosenthal alludes to the recent work on this subject by Vincenzo d'Amico, who believes that this is the only true method of treatment of pulmonary tuberculosis. The method consists in the introduction into the substance of the lung of a fine irridium pointed platinum needle 3 to 5 centimeters long. Through this needle there are injected into the diseased focus 1 to 2 cubic centimeters of the following solution:

℞ Iodoform, 1 gram.
Camphor, 2 grams.
Guaiacol, 5 grams.
Essence of peppermint, 30 drops.
Olive oil, 20 grams.

D'Amico is said to have obtained good results with the use of this method in the treatment of twenty cases of pulmonary tuberculosis.—*Bulletin Général de Thérapeutique.*

**Direct Transfusion of Blood in the Treatment of Hyperemesis Gravidarum.**—C. Viannay reports a case of incoercible vomiting of pregnancy in which he practised direct transfusion of blood from a normal pregnant woman. The vomiting stopped immediately. This method of treatment is based upon the method advocated by Le Lorier in 1911 and Freux and Dantin in 1912, by which the blood serum of a pregnant woman is injected into the vomiting patient. The latter method would commend itself by its greater simplicity.—*Journal de Médecine de Paris.*

**Emetine in the Treatment of Hemoptysis.**—C. Flandin recommends the injection into the thigh or flanc of 4 centigrams of emetine hydrochloride dissolved in 1 cubic centimeter of water. The result is an immediate arrest of pulmonary hemorrhage.—*La Presse Médicale.*

### FURTHER OBSERVATIONS ON THE OPERATIVE TREATMENT OF PARALYTIC TALIPES, CALCANEUS, AND ALLIED DISTORTIONS.*

By ROYAL WHITMAN, M.D.,

NEW YORK.

THIS paper is primarily concerned with the treatment of paralytic talipes. I shall call attention, therefore, to certain points in the construction of the foot, and to the effects of weakness and deformity upon its functions, in order to indicate more clearly the purpose of the operative remedy.

The astragalus, interposed between the bones of the leg and the tarsus without muscular attachments, is the center of all the important movements of the foot; dorsal and plantar flexion in its superior, adduction and abduction in its inferior articulations. As deformities are essentially fixed attitudes, it follows that the astragalus is also the center of all distortions.

The functions of the foot, in order of importance,

FIG. 1.—The Normal Foot.

are—to serve as a secure support, and to balance and propel the body.

The most important of all the forms of talipes is calcaneus, because paralysis of the calf muscle disables both functions, and induces a deformity that progresses in spite of mechanical restraint.

The os calcis, no longer supported by the tendo Achillis, turns on end, elevating the astragalus and increasing its inherent instability. The forefoot is usually drawn backward by the accessory muscles,

FIG. 2.—Talipes calcaneus.

exaggerating the cavus, and, having lost its capacity for weight bearing, it atrophies and becomes an appendage to the hypertrophied heel. If, as in many instances, the foot is distorted laterally, it becomes an incumberance, rather than an aid in locomotion.

This analysis indicates that the astragalus, the center of uncontrolled motion, or insecurity, forms also the salient part of the deformity. Its removal is indicated, therefore, as the essential preliminary to permanent relief. The laxity of tissue thus obtained enables one to displace the foot backward, and to implant the malleoli on its basic structure near the center. This equalizes the leverage and checks dorsal flexion by direct impact of the tibia with the scaphoid. Tendon transplantation, usually of the peronei, is a useful supplement to restore in some degree the power of plantar flexion.

By this procedure a range of serviceable movement is restored and deformity is reduced without violence. In fact, a moderate degree of cavus is of advantage in preserving symmetry and the excess is reduced by the transference of the pressure on the foot, whose weight bearing capacity has been restored. The operation, although most successful in cases of extreme distortion, is also effective as a preventive of progressive atrophy and deformity, and if it is properly performed, the results, both as to appearance and function, improve with the lapse of time.

In all these particulars it presents a striking contrast to other methods of treatment. For example: All operations for the correction of deformity are palliative in the sense that support is required to prevent relapse and to aid function. The same is

* A paper read before the Orthopedic Section of the XVII International Medical Congress, August, 1913.

true of tendon transplantation, as is indicated by comparison of the power of the calf muscle with that of the feeble lateral group that can be utilized to replace it. But one operation need be seriously considered in comparison. This is arthrodesis, by which security is obtained at the expense of motion,

Fig. 3.—Illustrating the immediate effect of the operation. See Fig. 2.

with consequent muscular atrophy. At best its range is far more limited, since operative anchylosis is impracticable until late childhood. Nor is it adapted for the more extreme type of calcaneus with lateral distortion. Even reduction of the cavus may require cuneiform resection of the tarsus as in Jones' operation. In successful cases, the foot is fixed at a right angle to the leg, or oftener in slight dorsal flexion, so that the weight, as before, is supported in great part on the heel. If, therefore, as in many instances, shortening of the limb is sufficient to require compensation, an unsightly cork sole must be worn, as contrasted with a higher heel, or in more extreme cases, an extension shoe, which may be applied when plantar flexion is retained.

A common criticism is that removal of the astragalus shortens the limb. This is only relatively true, for, since calcaneus deformity elevates the malleoli, its removal simply restores the symmetry, and even in cases in which the cavus is slight, the shortening does not represent the thickness of the astragalus, since the lower border of the tibia remains on the plane of the upper margin of the navicular.

This operation was first described in 1901,* and in my last paper on the subject, in 1910, I was able to report on the results in 50 cases, most of which were of advanced deformity of the calcaneus type.†

Since then the field has been greatly extended and a much larger number of operations have been performed. It has now become the treatment of selection in all cases of calcaneus in which the paralysis is evidently permanent, with the aim of restoring function and thus to check the progress of the atrophy and deformity, and to relieve the patient from mechanical support.

It is of service also in a variety of other forms of paralytic talipes associated with lateral instability, for example, in cases of equino-valgus, in which the distance between the malleoli and the base is increased, especially so if extensive paralysis of the other limb requires a cumbersome brace. It is indicated in cases of complete paralysis of the leg muscles, the so-called "dangle foot." Since backward displacement limits both dorsal and plantar flexion, and balances the foot, support is usually unnecessary, and if the thigh muscles are active, the patient may walk well, although both feet are involved. In cases of complete paralysis of the extremity, in older subjects, it may be combined with arthrodesis at the knee to restore the weight bearing capacity. Even in cases of spastic hemiplegic and paraplegic deformity associated with marked contraction, the results are very satisfactory.

Incidentally it may be mentioned that the operation is of service in quite a different class of cases:

For tuberculosis at the ankle, in which one aims to remove the disease, and yet to retain motion.

To restore motion at the ankle in cases of ankylosis, or of deformity and limited movement caused by fracture of the astragalus or of the malleoli.

A point to which I would call attention is that in cases of this class also the foot should be displaced backwards, although not, of course, to such a degree as to check dorsal flexion. If this is neglected the function of the calf muscle is impaired, and the foot is noticeably deformed. In other words, whenever the astragalus is removed the foot should be displaced backwards.

The details of the treatment as applied to a typical case of calcaneo-valgus are as follows:

The line of incision begins at a point about an inch above the extremity of the external malleolus midway between it and the tendo Achillis, and is continued downward and forward about three-quarters of an inch below the malleolus over the dorsum of the foot to the external surface of the head of the astragalus.

The sheaths of the peronei tendons are opened and the tendons are cut below the malleolous and drawn backward. The bands of the external lateral

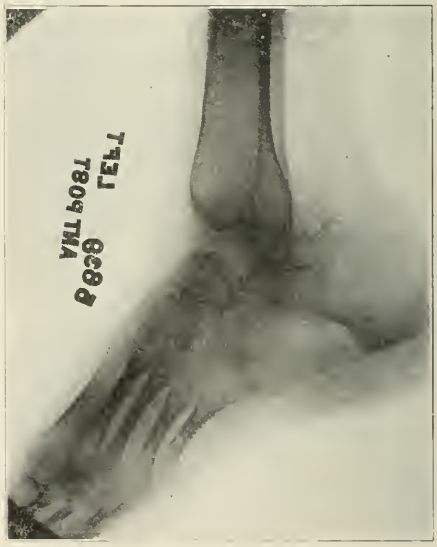

Fig. 4.—Showing a later result of the operation illustrating the limitations of dorsal flexion by contact of the tarsus with the tibia.

and interosseous ligaments are divided and the head of the astragalus is freed from its attachments to the tibia and scaphoid. An elevator is then inserted between it and the os calcis, and the foot being forcibly inverted, the head of the astragalus is drawn from the wound, and, the attachments on its

*American Journal of Medical Sciences*, November, 1901; *Annals of Surgery*, February, 1908.

†*American Journal of Orthopedic Surgery*, August, 1910.

inner and posterior borders having been cut or broken, it is removed.

One, then, prepares the new articulations. A thin section of bone is cut from the adjoining surfaces of the cuboid and os calcis. On its inner side a knife is passed about the internal border of the scaphoid and the ligament is separated by an elevator. The foot is then displaced outward and the malleoli are laid bare by dissection from their ligamentous attachments and are reshaped somewhat on their internal surfaces to fit the new articulations. The peronei tendons, freed from the lower extremity of the fibula, are passed through a slit at the base of the tendo achillis, sewn firmly to it, and then drawn forward and reunited to their distal extremities.

The foot is now displaced backwards, the external malleolus overlapping the calcaneo-cuboid articulation, the internal the navicular. The wound is then closed with catgut sutures and the foot is fixed by a plaster splint in an attitude of moderate plantar flexion and abduction.

In the routine of hospital practice the operation is performed under the Esmarch bandage. The tendons are sutured with Lange silk. The wound, having been cleansed with warm saline solution, is closed without drainage. The foot and limb are bandaged with sterilized sheet wadding, over which a light plaster is applied, holding the foot in the attitude described, and the leg at a right angle to the thigh. The limb is afterward suspended between tapes running from the head to the foot of the bed. Great care is taken to avoid constriction. To this, and to the rest assured by the plaster splint, and to suspension, is ascribed the very slight discomfort following the operation, and the absence of complications.

At the end of about three weeks the first support is removed, and the walking plaster splint is substituted, extending to the knee, and fixing the foot in the same attitude of moderate equinovalgus, the sole being equalized by the incorporation of a wedge of cork. The patient is encouraged to walk with equal steps, and to bear weight on the forward part of the foot. At the end of from four to six months the new joint will have become stable, and the fixed support may be discarded for a shoe arranged with a cork wedge beneath the heel, of sufficient thickness, is compensated for slight equinus, and if necessary the outer border of the sole is thickened somewhat to prevent a tendency to inversion.

Even in the cases in which after treatment has been neglected, the nutrition of the limb and the appearance of the foot improve with the gain in functional ability, and some of the patients walk so well as almost to merit the term "cure," as applied to cases of this class.

As has been stated, tendon transplantation is utilized whenever practicable in the treatment of these distortions; the transplanted muscles working at a mechanical advantage because deformity has been restrained. This is, however, a distinctly subordinate part of a procedure which of itself assures security by limiting movement to the range that is under control. I take great pleasure in presenting this operation for your consideration, as an assured remedy for the most disabling, the most deforming and the most intractable of all the paralytic distortions of the foot, which has, as yet, if one may judge from the literature, received no practical recognition from my European colleagues.

# EXTIRPATION OF BACILLUS DIPHTHERIÆ BY MEANS OF A THALLOPHYTIC FUNGUS, ACHLYA MUSCARIS.

## A CLINICAL AND EXPERIMENTAL STUDY.*

By L. L. TEN BROECK, M.D.,

MINNEAPOLIS, MINN.

*Introduction.*—The success of preventive measures as compared with curative methods in the control of disease is so vastly more efficient and so apparent as to need no argument. Efficient a drug as is quinine in the control of malaria, its achievements by no means begin to compare with results obtained by extirpating the plasmodium through the destruction of its host, the mosquito. So there is abundant reason why, in spite of the brilliant therapeutic attainments following the introduction of antitoxin, further search must be made for a method which exterminates the *B. diphtheriæ* in a way that can compare with the extirpation of the organisms of malaria and yellow fever. The limitations of the life history of the *B. diphtheriæ* de-

Fig. 1—Cultures of diphtheria baccillus, destroyed by Achlya, A, diphtheriæ on blood agar. Control showing vigorous growth. B, diphtheriæ inoculated after 24 hours' free growth on blood-agar with Achlya; nearly complete bacteriolysis shown by the absence of the usual streak (the light spots are due to scratches and breaks in the media), a few ill-staining forms can still be scraped from the field. C, subculture from B on Loeffler's after 72 hours' mixed growth. Photographed after four days' incubation, no growth (the light spots are artifacts).

mands means that are effective during the time this organism is a prey on human tissues. Such a method must therefore be suited to the acute stages of this disease.

*Methods in Vogue to Exterminate B. Diphtheriæ from Human Throats.*—(1) Antiseptics locally applied. (2) Immunization, active or passive. (3) The use of antagonizing bacteria or their extracts; (a) having demonstrable bactericidal properties; (b) luxuriant growers, "over-riders." Detailed discussion of these methods is impossible in a preliminary report, and no more than enough can be said to obtain clear understanding of the method about to be described.

Antiseptics: It would be difficult to find a more exhaustive and painstaking work than that of Loeffler[1] in his early search for a reliable germicide for this organism. The fact that this worker speedily abandoned this field for that of biology ought to be

*The clinical properties of this fungus were first discussed by the late Dr. C. P. Bunsen. His infirmities prevented a thorough laboratory study of its reactions. At his request I took up the work anew, and the following report is based solely on independent work. This note is inserted in order that credit may fall where due.

substantial evidence of its limitations. It is, of course, possible to produce laboratory evidence in the form of cultures taken from the throats so treated, for the area of the throat accessible to cultural methods is strictly limited to the area under

Fig. 2.—Diphtheritic cast of uvula, Case No. 20 F. C. Removed 72 hours after fungus inoculation. No recurrence clinically, but cultures positive until fifth day. (See Fig. 4.)

control of local treatment, leaving the inaccessible points unknown quantities.

Immunization has its drawbacks. One encounters a prejudice and not without reason, for in immunizing the well and allowing germs to run riot so far as propagating is concerned in the sick, is taking a course as logical as to lock up law-abiding citizens and letting malefactors free. Nevertheless, much credit is due Hewlitt[2] and others for their work in active immunization whereby the efficiency and durability of immunity is much advanced. Recently von Behring[3] has opened up new possibilities for immunizing measures. However, there is a growing belief that modern immunizing methods depending upon the circulatory fluids to distribute protective agencies to the desired focus are liable to fall short of the mark, and must be supplemented by other measures that have a more direct attack on the focus of infection.[4] This point has been recently thoroughly discussed by Flexner.[5] The converse is also true, that antigen may be abundantly produced in areas from which it reaches the circulation in amounts too insignificant to provoke a serological response.[4] Speaking in terms made familiar by the immunologist, the phagocytes and similar factors quit (using a common term) before the work of cleaning the mucosa is complete. Following the modern tendency to reproduce artificially natural factors the idea suggests itself of introducing into these areas substitutes for these phagocytes and their coworkers. Whatever be the *modus operandi* of these natural factors, it is eventually bactericidal. So we may expect satisfaction from artificial factors if they can combine bactericidal activity with a power of migration and extension such as brings the natural leucocyte into all areas the seat of bacterial invasion. The migratory powers of leucocyte and bacterium differ widely. The bacterium only occasionally possesses power of migration *per se*. This is effectual chiefly in conditions of stasis (urinary, etc.). In the majority of instances, unless borne along by the circulatory fluids (metastatic), or by the fluid contents of some physiological canal (urine, bile, in ascending and descending types of infection), the bacterium makes his progress by contiguity. The leucocytes are infallibly, though at times inadequately, drawn to the seat of infection by a process known as chemotaxis. Inasmuch as there is this limitation in migratory powers of bacteria and other fungi, their use as scavengers in place of leucocytes, will meet with sharp limitations, and to compete with chemotaxis of the leucocyte their circumscribed migratory power must be supplemented by artificial means. Thus to bring a given area into the scope of such scavengers may require repeated inoculations, or inoculation within a given zone (*e.g.* inoculating direct into a nasal sinus instead of anywhere on the nasal linings), or the field may require special preparation. These remarks are made necessary by the general tendency not to fully sound the limitations of a new procedure and to fall into error in its application. It is well to repeat that there will occur great differences between the migratory power of the true and false leucocyte when any form of fungus plays the rôle of the latter.

Emphasis should be placed on bactericidal properties. It is possible to introduce a very luxuriant growth into an infected field in quantities sufficient to mask the original invader when the area is subsequently tested by the ordinary swab and cultural methods. Whether such an area is in reality toally rid of its infection is questionable. Dr. Corbett, city bacteriologist of Minneapolis, in a case of postdiphtheritic otitis media, found nothing but streptococci on Loeffler's media. Irrigation with weak phenol inhibited its growth and subsequent cultures showed pure *B. diphtheriæ*. So long as the streptococcus was present in culture or in the ear, uninfluenced by irrigation, no diphtheria bacilli could be found, but they could again be recovered from the ear after irrigation as described. I have been able in several cases to isolate pure cultures of streptococcus by a single animal passage in which competent bacteriologists have failed to find any trace of this germ by ordinary cultural methods.

This uncertainty is avoided if an active bacterio-

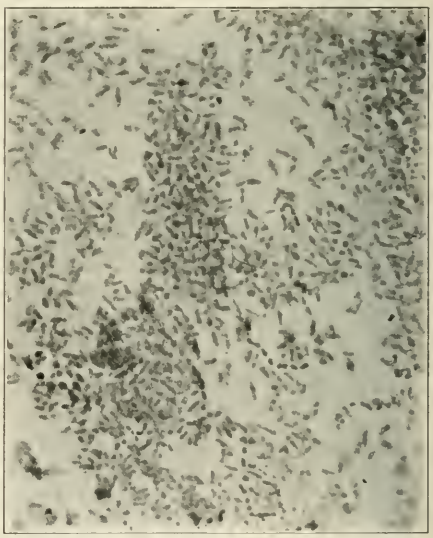

Fig. 3.—Case No. 20 F. C. Smear from culture taken just prior to inoculation with fungus showing groups of diphtheria organisms with cocci.

lytic ferment or bactericidal extract is present in the germ-free filtrate, as shown in the case of pyocyanase.[6] A simpler and equally convincing demonstration can be made provided the cultural characteristics will permit the infecting organism and its

antagonist to grow together on a common medium and yet provide another medium which supports the growth of the former, but will not allow the growth of the antagonist. Combined growth on the former medium will result in a destruction of the original

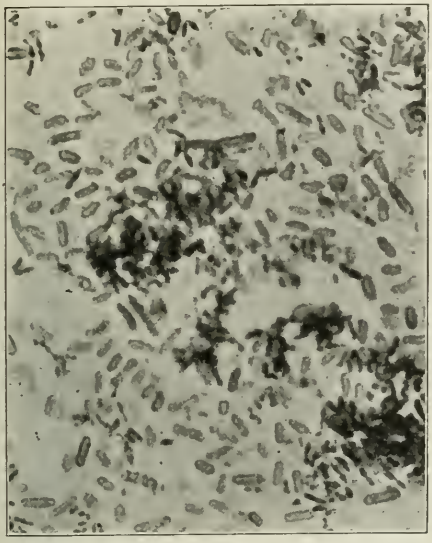

Fig. 4.—Case No. 20 F. C. Smears from culture taken the fifth day after inoculation with fungus showing no diphtheria organisms, numerous cocci and an unidentified long bacillus.

invader and subcultures from this combined growth transferred to the second medium will show no growth. This last medium will, however, support fresh inoculations from the original invader. This phenomenon is entirely different from that which is exhibited when an organism growing luxuriantly both on the throat and bacteriological media is used. Nevertheless, if it can be shown clinically that the use of this last type does prevent diphtheria contagion, the fact must be accepted as empirical, and such methods will be accorded a welcome place in our therapeutic armamentarium. There will always be an attempt made, however, to produce factors that follow more closely natural methods.

If bacteria or molds lack some of the desirable features of scavengers when compared to leucocytes they possess others highly desirable in keeping with their kind. If they are spore producers they lend themselves readily to infecting others, so that the treated patients disseminate the appropriate scavenger as well as the disease-producing body, and in so far as a scavenger is selected in which methods of dissemination surpass those possessed by the original infection, the chances are so much the greater of supplying artificial leucocytes instead of the contagion, so called. In contagion we are apt to see nothing but evil, but if this can be substantiated in practice there will be a contagion for good as well as for evil.

To produce an organism that meets these qualifications and brings the foregoing principles down to a working basis is a huge task demanding a wide scope of experimental investigation. The following data are but a small fractional part of this. There are, however, certain striking and notably constant phenomena attendant upon the use of this fungus in a variety of experimental conditions. Furthermore, the clinical evidence is sufficiently abundant to make an extensive and safe clinical trial possible, while the experimental and biological features are well enough demonstrated to direct further experimentation.

*Description of Thallophytic Fungus, Achlya Muscaris. Classification.*—The organism belongs to the group of thallophytic fungi as distinguished from fission fungi, or ordinary bacteria—genus *saprolignati*. It corresponds to the description of the *Achlya muscaris* given by botanists.[7] *Penicillium glaucum* (bread mold), *Oidium albicans* (the organism of thrush), *Aspergillum* (described by Sahli[8] and Chute[9] as pathogenic for the respiratory and urinary passages) are closely related fungi. The genus is for the most part saprophytic, and more often parasitic in animals (salmon, insects) than in man. Infections in the human being are self-limited and easily amenable to treatment.

Life History.—It occurs in nature as a parasite on the fly, covering this animal with a barely discernible down, causing an intense thirst and generally death. The thirst is revealed by constant drinking. The fungus can be artificially grown on the human throat, but so far as I know has never occurred there unless intentionally placed there.

Morphology.—It forms a felted mass composed of intertwining and branching mycelia that are capped with a lance-shaped sporangium which grows more spherical on maturity. In size it is relatively minute, measuring in width but twice the diameter of an erythrocyte. Mounted in liquid media and examined with a dark field its mycelia are seen in motion resembling the swaying of a tree top.

Staining Characteristics.—Molds stain with difficulty. The method that has proved most satisfac-

Fig. 5.—Case No. 21 B. R. Smear from culture taken the first day of treatment with fungus; numerous diphtheria organisms and few cocci.

tory is the India ink method following the technique of Kenneth Taylor,[10] to wit, artificial cover glass slips made from glycerin agar.

Cultural Characteristics.—Like all molds, it grows luxuriantly under favorable conditions, but its

growth is very susceptible to alterations in these conditions. Ordinary media will not support its growth unless impregnated with some particular substance. So far human blood has been used. It also requires an abundance of moisture. The color of blood slowly changes to pink, a valuable index of growth. Mixed with a little blood and a 24-hour bouillon culture of *B. diphtheriæ*, there is a complete destruction of the latter generally in forty-eight hours. Inoculation of this mixed growth at the expiration of this time into fresh blood free bouillon is negative, but the same bouillon supports a fresh inoculation of untreated *B. diphtheriæ*. The same holds good when solid media are used, but the process is slower perhaps for relative dryness. Blood bouillon cultures filtered and tested to be spore free will not support a growth of *B. diphtheriæ*. Further anaylsis of the active principle in this phenomenon has not been carried out.

Animal Inoculation.—Intraperitoneal inoculations in guinea pigs are negative, except for the slight

Fig. 6.—Case No. 21 B. R. Smear from culture 48 hours after fungus inoculation; nothing but cocci; a clinical and bacteriological cure without antitoxin; in this case the diphtheria disappeared before the membrane.

irritative phenomena that follow similar procedures with non-pathogenic growths. A series of controls was inoculated in the vagina. All died in three to six days, some with an insignificant vaginitis and some in spite of large doses of antitoxin. All gave positive diphtheria cultures at some stage of the disease. Necropsies were made on all with uniform findings—a local diphtheritic process not involving the uterus or causing a general toxemia. Another control was inoculated and a fresh animal. Three days later, when both were quite ill, the second animal being very much so, the second was inoculated with the fungus. Control died two days later with considerable vaginitis. Treated animal made a steady improvement, especially in vaginitis. Six days later it again became ill, without any noticeable change in the vagina, and died on the twelfth day following the original inoculation with *B. diphtheriæ*. As both animals were kept in the same pen, there is reason to believe from the clinical course that the second animal was re-inoculated. Necropsies on both were the same as described. Blood cultures negative. Difficulty was encountered in obtaining diphtheria cultures on account of overriding by secondary invaders. Positive cultures were obtained from the control for five days, from the treated animal for two. There are some unsatisfactory features about this test, the secondary invaders, opportunities for re-inoculation and delay in treatment until the animal was so far gone. Nevertheless, the results support the cultural findings, though not with the clean-cut decisiveness. It is believed that by eliminating these disturbing factors more striking evidence can be adduced.

*Certain Observations in Clinical Cases.*—When sown on normal throats, after a few hours patients complain of a scratchy feeling. Some injection is seen on the fauces, later an almost indiscernible covering develops, resembling a membrane as hoar frost resembles a snow fall. This is best seen at the junction of the soft palate and uvula. It gradually and unnoticeably disappears, but occasionally persists, especially in diseased throats, where it readily yields to antiseptic treatment, mercury exerting a rapid influence. When concentrated to one spot the spores produce some local irritation immediately, which can be relieved by copious gargling with warm water. Systemically a feeling of malaise is sometimes experienced of short duration. This occurs too early to be due to fungus propagation, and is probably due to absorption of the cultural products of the inoculation material or to preformed toxins of the bacteria there propagating, but whose absorption is hastened by the induced hyperemia, etc., analogous to the urethral chill that follows catheterization. It has given rise to no complications in sixty-five cases. One case is rather convincing proof of its harmlessness.

Case I.—Patient suffered from recurrent tonsillitis frequently suppurative. Patient always insisted on removal during the acute and painful stage, but refused operation during quiescent stage. Convinced of a quite general inhibitory action on the part of the fungus against the throat pathogens it was thought that a combination of bacterin and fungus treatment would permit of a relatively early removal of the tonsils. Operation wholly successful except that the throat was somewhat more septic than a quiescent case and much less septic than could be expected considering the condition of the tonsils. Inasmuch as the operative trauma invited every possible complication from the fungus it is clear that this organism has very limited pathogenic properties.

If this fungus possess strong bactericidal properties it ought to prove itself curative unaided by other means. Anticipating the clinical tables it may be said that the fungus seems to remove membranous anginas of various origin. Given a case of membranous angina not seriously sick enough to demand immediate antitoxin it is apparent that the fungus can be inoculated and be doing its work many hours before the diagnosis has become established. When there was at the same time a clinical improvement that one by practice can detect, we felt justified in the face of a favorable outlook to let the case progress without other treatment. These cases form the most striking demonstration of the action of this fungus.

The Pharyngeal Cases.—Almost invariably diphtheria makes its clinical manifestation in the throat. As a matter of laboratory knowledge the nasal discharges are contaminated in over half, perhaps 75 per cent. of the cases. This fact was not fully appreciated by us at the beginning of our work.

and we confined our attention to the pharynx. It would appear that the reaction that was successful in the pharynx could be carried on in the nose. Remembering the discussion at the beginning of this report, it would appear that bacterial or fungus migration was circumscribed and therefore a special technique for nasal inoculation might be required for complicated nasal cases.

As a matter of fact, attempts to inoculate nasal sinus by a deposit of spores on the tonsils has not proven successful. The critical point is whether the usual growth of the fungus and the usual field of diphtheritic invasion are coextensive at a comparatively early period of the disease. If special conditions arise in which the fields of invasion have different limits a special technique either in number of inoculations or in the site of inoculation must be devised. In the pharyngeal cases the pharynx only was cultured and that for a period considerably over a week. It would seem as though any diphtheritic discharge in the nose would at some time or other inside of a week contaminate the pharynx and give a positive culture. While the evidence is all in favor of a total extirpation of the *B. diphtheriæ* these remarks are inserted to insure that the question be neither misunderstood or overlooked, and that a careful control over these conditions be exercised.

A.—Twenty-five cases of simple follicular tonsilitis: Here a reaction occurs similar to or more marked than in normal throats. There is a rapid disappearance of the membrane without any loosening of the same in mass, a clinical characteristic that aids in distinguishing the non-diphtheritic exudate.

The treatment was adopted in suspicious throats and in others to test out the effect of the fungus under pathological conditions.

Case II.—M. W. Clinical diagnosis: follicular tonsillitis; bacteriological examination not made. No improvement after 43 hours local treatment. Antiseptics removed by copious gargling and throat innoculated in evening. Throat clear in morning. In the extreme types of diphtheritic cases one occasionally notices a persisting easily detachable exudate and slimy condition of the throat. This rapidly clears up under antiseptic treatment.

In a very severe case of combined scarlatina and diphtheria, in which the latter disease developed seventy-two hours after, and in spite of a prophylactic injection of 3,000 units noma developed despite a brilliant destruction of the diphtheritic membrane. Antiseptics were used for only one day, then refused. The case went on to a fatal termination. The only explanation that is in accord with other findings is that the destruction of the membrane left a raw wound that invited infection and noma, the fungus having been destroyed by natural processes or by the early use of antiseptics.

B.—Seven cases with mild diphtheritic tonsillitis: Five of these cases have been treated without antitoxin, their progress having been sufficiently satisfactory without to warrant letting them alone.

The procedure is not at this time recommended, but was adopted to demonstrate the efficient bactericidal properties of this fungus when unaided by other means.

Case III.—A. Z. Child, six years. Mild diphtheritic tonsillitis, diagnosis confirmed by culture. In 29 hours a well developed fungus growth with a peculiar fibrillation and loosening of the membrane was taken as evidence of success in membrane destruction. This, coupled with the fear of the antitoxin needle, led to the discarding of further measures. In 48 hours there was no positive culture nor any time afterward. Recovery rapid and uneventful.

Fourteen cases of somewhat severe throat involvement, with mild constitutional symptoms: Eleven of these cases were treated without antitoxin, one being a frank case of diphtheria, two showing typical forms in culture, the rest giving negative cultures. The three additional cases each received 1,000 units.

Case IV.—F. C. Severe involvement of tonsil and uvula. *B. diphtheriæ* promptly disappeared, then reappeared in nearly pure culture and was again not found and permanently diappeared on the fourth day. On the third day the membrane was stripped from the uvula like a finger cot. No recurrence. No antitoxin.

Case V.—G. D. Clinical diagnosis diphtheria. Atypical forms in culture. Much edema. Atypical forms disappeared in 48 hours showing only staphylococci. No antitoxin.

Case VI.—W. F. Clinical diagnosis diphtheria. Atypical forms in culture disappearing in 48 hours. No antitoxin. Rapid healing of throat.

Fourteen cases of malignant-looking throats and severe prostration. Nine cases were diphtheritic, one complicated with scarlatina. Two of the diphtheritic cases were treated without antitoxin, the remaining diphtheritic cases receiving appropriate doses.

Case VII.—Wo. Extreme edema and much prostration. Cultures nearly pure diphtheria bacillus, especially on second day. *B. diphtheriæ* absent on and after third day. Throat nearly normal on the seventh day. No antitoxin.

Case. VIII.—B. R. Characterized by extreme edema and severe prostration. *B. diphtheriæ* present on first and second day, subsequently absent. Recovery rapid and uneventful. No antitoxin.

Case IX.—D. A. Seen in consultation on the third day. Made clinical diagnosis of diphtheria and injected 3000 units at once. Cultures positive for three days only. Membrane rapidly disappeared but much painful infiltration of pillars on right side resistant to all forms of treatment. Yielded to autogenous vaccines subcultured from first day's culture (staphylococcus).

Six cases with malignant-looking throats and extreme prostration. These are the fulminating, not discovered till late in the disease. Two were rapidly fatal, one an infant of two weeks for whom all treatment was refused except one inoculation. The second case showed not the slightest improvement from 30,000 units given in eight hours, developed multiple petechiæ and died in 72 hours. This case was complicated with scarlatina and death was quite likely due to a general streptococcemia. The membrane, however, was in a large part disintegrated at death. A third fatal case of noma has been described.

Case X.—Si. Treated for five days as a follicular tonsillitis. Seen in consultation on the sixth day. Prostration very extreme. Diagnosis diphtheritic laryngitis and pharyngitis. Twelve thousand units given and fungus inoculated. Child insisted on sitting up the following day. Recovery uneventful. *B. diphtheriæ* absent after 48 hours.

Nasal Cases: No nasal cases have been treated during the acute stage. Through the kindness of Dr. Mullin I was able to treat a case of a bacillus (non-pathogenic) carrier whose throat cultures were generally negative and nasal cultures generally positive. Inoculation by the throat was adopted. A rather vigorous growth followed a single inoculation with a comparatively strong but harmless reaction. No alteration was noticeable in the diphtheria cultures. Owing to spore growths it was impossible to test the reaction *in vitro*. It would seem as if there was an area of the nose the seat of diphtheritic invasion into which the fungus had not penetrated at least from a single inoculation. These chronic cases afford a study distinct from the acute and it was thought best to work out nasal reactions and conditions in acute early cases.

For the chronic discharges the method of topical nasal application suggests itself and is worthy of trial.

Non-Diphtheritic Cases: Experimental investigation has up to this writing covered only cases of Loeffler's bacillus. In membranous anginas of other origin there appears to be a rather constant improvement equal to that in the true diphtheria. Contamination of *Staphylococcus albus* in achlya cultures have survived for weeks. Pneumococci and streptococci have promptly disappeared from cultures mixed with achlya and accidentally contaminated with a spore-bearing organism developing in the blood. These experiments are to be repeated.

Case XI.—T. B. Stormy onset with rigors and fever 105. Fauced injected for two days then a suspicious membrane. Clinical diagnosis non-diphtheritic angina probably pneumococcic. Pneumococci found in culture nearly pure. Fungus inoculated and an injection of dead pneumococci given. Very prompt disappearance of membrane and of pneumococci from culture (48 hours).

*Preparation of Spores.*—The original method was to grow the fungus on defibrinated blood to wait ten days for spore formation, then filter. Ordinary filter paper will by deposit of albumin soon become a fair filter for the spores. The method is tedious and objectionable. The fungus grows on one-half to one-tenth of one per cent. blood dilutions and can be filtered from this. Methods of filtration are now being studied. The amount of human blood necessary is very small and easily obtained. No doubt there is other media as suitable as human blood but it is desired to introduce no other factors in the problem at the present stage. *Oidium albicans* can be made to produce spores with great prolificity in a media of glycerin agar and eosin. No doubt the problem of propagation, now simple enough to be useful, can be further simplified.

The spores and filtrate are mixed with ten times their weight of lactose as a diluent. They can be applied in amounts of 5 to 7 grains of the mixture direct on the tongue or may be gently deposited as a powder by blowing. If too much is deposited at one point some irritation can be expected. Antiseptics must not have been used or must first be removed by copious gargling. A second inoculation in three hours is usually required. In six more hours signs of growth are generally noticeable. Towards the close of 24 hours mild antiseptic gargling is generally beneficial and hastens the clearing up of the throat. Sometimes it is necessary to reinoculate after removing antiseptics as a recurrence of the membrane has taken place in four instances—in two checked by antitoxin, in two by re-inoculation. Antiseptics were avoided in cases subject to bacteriological study.

*Control of Contagion.*—Important as is the question of bacteriolysis of the diphtheria germ, of greater importance is the question whether a mem-

brane in which the *B. diphtheriæ* is still propagating on which also the fungus has taken root, if it becomes a source contagion, will not infect the second individual with the fungus rather than with the diphtheria germ or at least limit that germ to a very short-lived and harmless existence.

Experiment on the control of contagion: A Coplin staining jar with slide was sterilized, and under sterile precautions the slides were smeared with human blood mixed with melted agar. In one set as a control *B. diphtheriæ* was grown. In a second set one slide only was doubly inoculated with *B. diphtheriæ* and the fungus, the rest inoculated with *B. diphtheriæ* alone. Both sets were incubated. In the set which included the single inoculation of the fungus there was not a solitary growth of *B. diphtheriæ*. There was a growth, however, in the control. It is essential to keep maximum humidity by placing sterile water in these jars.

The results on animals have been discussed. After considerable experimentation I considered it safe for a clinical demonstration and accordingly I inoculated my own throat with a diphtheritic membrane eighteen or so hours after I had inoculated the patient with the fungus, at which time I thought I recognized signs of fungus propagation. I suffered from a slight faucial congestion but no *B. diphtheriæ* were found in my throat. The condition passed away without treatment. This I have repeated in two other instances. The significance of this is apparent inasmuch as, if it is true, it means that every diphtheritic throat can be rendered non-contagious in less than twenty-four hours, probably in twelve hours. It must be remembered that there are other avenues of infection besides mouth to mouth, and that during the incubation period the disease may be widely disseminated. In promptly controlling mouth-to-mouth contagion the greatest menace is eliminated.

*Conclusions.*—1. *Achlya muscaris* possesses the power of destroying *B. diphtheriæ* in culture and in the throat.

2. Throat inoculations of this fungus are usually self-limited and may require some adjustment in the way of repeated inoculations or inoculation in special areas or under special conditions to embrace all complications in the nose.

3. It has the power of inhibiting the growth of a number of throat pathogens and seems to influence favorably membranous anginas of various origin.

4. Its clinical use seems to be attended with no danger but after treatment with mild antiseptics is recommended to remove the fungus.

5. It is applicable in all stages of the disease and seems to give speediest results in the early cases.

6. There are grounds for believing that a throat in which this fungus is growing is soon shorn of its danger of contagion even if the diphtheria bacilli are still harbored.

7. It is admirably adapted to the clinical requirements for reliable and ready use.

These conclusions are offered not as definitely established, but as established in so far as the limited observations here recorded can establish any conclusions.

My hearty thanks are due to the members of the Department of Medicine, University of Minnesota, and to Dr. Corbett, Dr. Woodworth, and the Staff of the City Bacteriological Laboratory, to Dr. P. Heineman of the University of Chicago, to Dr. Mullin of the Minnesota State Health Board, and to the laboratories of Parke Davis & Co., and H. K. Mulford & Co. for the material placed at my disposal, and for their kind help.

## FOUR CASES OF CORNEOSCLERAL DERMOID TUMORS.

By DR. JUAN SANTOS-FERNANDEZ, M.D.,

HAVANA, CUBA.

Dermoid cyst, as is known, designates a tumor containing substantial parts of the skin, as hairs, teeth, nails, and ordinarily produced by the invagination of a flap of skin in the course of the development of the embryo. Its habitual site is the neck and the angles of the eyebrows, but as it may also exist in any other region of the body as well as about the eyes, I shall describe four cases of this condition which I have observed in a long ophthalmological practice, during which I have kept the records of more than fifty thousand cases of eye patients. Dermoid cysts, while not being rare, are, at any rate, not common, and that it is convenient to exercise them in order to avoid the obstacle that they happen to offer at the palpebral border. These tumors, although benign, leave a certain amount of deformity that would be smaller if the tumor were operated upon during childhood, although the tumor, as well as its surface of implantation after its removal, develops at the same ratio as the eyeball. This was observed in the first case to be described, a child that was operated upon when a few months old, and that has been kept under observation until the present time, when he is a prosperous merchant thirty-two years of age.

Case I.—Infant J. J. A. 43 days old, well developed and of healthy aspect. On his left eye, there could be seen a small tumor, of white color, the size of a grain of millet, that on first sight appears to be a staphyloma of the corneoscleral junction Fig. 1. Its situation was at the inferior and somewhat external border of the corneoscleral limbus. His mother stated that on the third day after the birth of the child, she noticed the presence of the small tumor, which increased somewhat in size, because it did not strike against the free margin of the lower left eyelid, as it does now. It seems on first sight as if the lower part of the iris were attached to the tumor, but this is not so. The mother did not want to have the child operated upon at so early an age, but on September 16, 1882, four months after the first consultation and when the child was yet less than six months old, I excised the tumor

under chloroform anesthesia. As the operation appeared to be insufficient I repeated it five months afterward. The second time it was difficult to fix the small tumor with the fixation forceps but I passed through its base a sharp hook and then excised it with the scissors. As the borders of the incision were still defined after the excision, I re-

Fig. 1.

duced them with the fixation forceps and the knife. The center of the solution of continuity appeared somewhat obscure as if the choroid could be seen through it. The tumor after its separation looked somewhat concave on its inner or adherent surface. Two months afterwards, when the immediate after-effects of the operation had disappeared, the lower lid could be closed without having the obstacle that the tumor presented before. The surface of the cornea and of the sclera where the tumor had been appear slightly raised, more so than when last seen and looked like a small wafer adherent to the iris. I kept on seeing the patient until he was 18 or 20 years old. At this age I discovered on the fundus oculi the disk with a slight posterior staphyloma. Vision in this eye was defective as he could only count fingers and this could not be corrected. He insisted on having his leucoma covered with tattooing but this was only possible on the part affecting the cornea. After twenty years we did not see him again. The opacity, since the excision of the tumor, grew naturally with the eye, but always kept the same proportions with it. Finally very recently we met him in a theater and he greeted me but I naturally could not examine him at that place. Now he is 31 years old and he states that he has observed no changes after the last time I saw him and he has succeeded in the theatrical business. I invited him to visit me in order that I might make a thorough examination. This was the first case of dermoid cyst recorded by me and the one I have followed the longest.

Case II.—J. N. C. 19 years old, He states that on his third month after birth a "stain" was noticed on his right eye on the white towards the outside and almost on the sclera. When I examined him I saw a small tumor the size of a pea, situated outside of the periphery of the cornea and near the limbus Fig. 2. On the surface of the

Fig. 2.

tumor a hair could be seen. Using the fixation forceps only, instead of passing a sharp hook through, as in other cases, I immobilized the tumor and with the scissors separated it at its base, leaving uncovered the surface of attachment, and to diminish this I applied the thermo-cautery with the result that the borders and the raised surface receded. I did not see this case again.

Case III.—M. J. C. 19 years of age. Has had since birth a stain in his right eye. When seen an opacity was discovered on the external and lower part of the right cornea affecting also the sclera. It had a dull white color and had some vessels on its periphery. Its size is that of a pea (Fig. 3), and had not increased much. The pupil was normal and central. Operation was postponed but I did not see the patient again.

Case IV.—G. S. M. a boy 4 years old was brought by his parents to my office on February 24, 1913. They related to me that a month after the birth of the child they noticed a small white stain on the left eye and that the family physician said that it was a congenital manifestation. On the lower and outer part of the periphery of the cornea,

Fig. 3.

occupying an equal area of the cornea and of the sclera a small white tumor could be seen, the size of a pea and on its surface the parents had discovered and I also saw several very thin hairs (Fig. 4). Although the tumor was only

Fig. 4.

slightly raised on its base this small elevation was sufficient to cause the lower lid to strike against it and when the child was asleep the eye stayed half open. Under chloroform anesthesia, I passed a small sharp hook through the tumor and excised it with a good pair of scissors. As the border of the raw surface remained more raised than the middle, I employed a small knife and the forceps to level the entire surface. After excision, there were no obstacles to the closing of the lower lid. I observed him for several days after the operation and finally the remaining opacity at the site of implantation, as it was situated in the inferior border of the cornea, was partly covered by the left lower eye lid. The microscopical examination is as follows: Specimens examined were two small pieces of a hard tissue with some fine hairs on one of their surfaces. Under the microscope there was seen a subcutaneous node of fibrous connective tissue, covered by a thin layer of epithelium with some hair follicles. There are zones of infiltration with round cells of chronic inflammation as can be seen in Fig. 5.

I may repeat that corneal dermoid cysts, as those of the conjunctiva, are congenital tumors characterized chiefly by having in the interior normal cutaneous elements: hairs, sebaceous glands and portions of stratified or cylindrical epithelium. They are well known in their evolution and almost so in their pathological process, but their history is somewhat recent, and in this elucidation there have contributed Galenga, Lannalonge, Van-Duyse, and Cosmettatos. In reference to the symptomatology of these growths we ought to remember that dermoid cysts are always congenital. Owing to the lack of intelligence of the parents these growths are frequently not observed until the period of second dentition. When the tumor is quite visible the child is not taken to the ophthalmologist. On questioning the parent the congenital origin becomes evident. The upper and outer quadrant of the cornea, or the external border, is considered as the elective site of implantation of the neoplasm, but this rule is not absolute. Two of my patients had the cyst on the outer border. But the cysts can be in any other part of the cornea or on the sclera, and the case described by Demours in which the dermoid was situated in the inner angle of the eye,

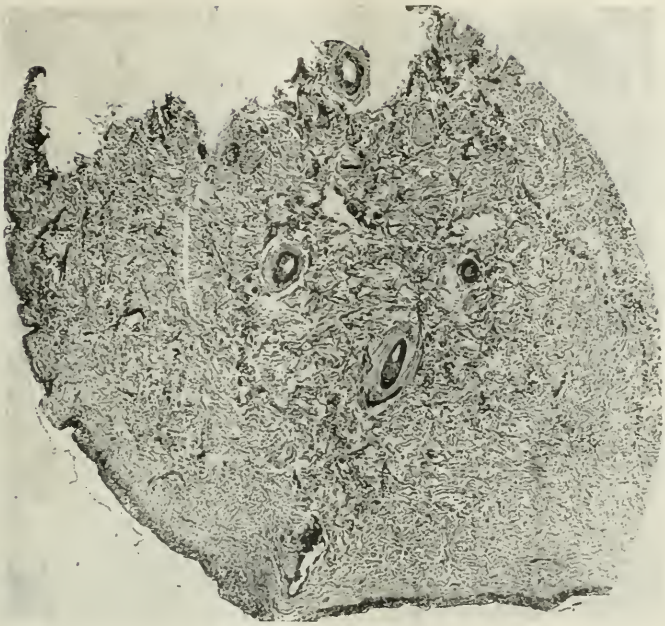

Fig. 5.

far away from the cornea, is well known. Although my cases attained the size only of a pea, some have grown to the size of a small olive. These cases have been single and not multiple, as that described by Picqué, Horner, Collomb and Lannelonge. The usual form was that of a truncated cone, as seen in Figs. 1, 2, 3, and 4. As seen in the description of the cases, the growth has been, up to puberty, slow in relation to the growth of the body. The dermoid in my cases were not prominently felt through the lids, but in Cases 1 and 4 (Figs. 1 and 4) they hindered the normal closing of the lower lids. In three of the cases (1, 2, and 4), although the tumor rested on the sclera as well as on the cornea, after excision it was seen that the base of implantation was only on the cornea. This also happened, but more strikingly so in Case 3. The substance of the dermoid in all our four cases was hard, fibrous, and somewhat like cartilage. In two of them hairs were seen. In no cases did I see glands. As always happens, these cases had a very slow growth. Histological examination was made only in Case 4 (Fig. 5), and this did not differ from the facts so far observed.

The dermoid, as mentioned above, in its beginning has several layers of skin: epidermis, dermis with its papillæ, hair follicles, sebaceous glands attached to the hair follicles, and sometimes, but very rarely, sweat glands. Many theories have been advanced to explain their cause, and those of Van Duyse, Lannelonge, and Vassaux are worthy of attention.

**Emetine in Hemoptysis.**—Flandin has employed emetine in the treatment of a number of cases of pulmonary hemorrhage with excellent results. He gives it hypodermically in doses of gr. 3/5 (0.04) of the hydrochloride in mxv (1.0) of water. The injection may be repeated in twelve hours, and again after the same interval.—*Presse Médicale.*

## A MODIFIED METHOD OF LAVAGE BY MEANS OF A DOUBLE-COCK GLASS PIECE IN CONJUNCTION WITH THE MODIFIED STOMACH-TUBE ESPECIALLY ADAPTED FOR THE OFFICE AND HOSPITAL WARD.

By I. O. PALEFSKI, M.D.,

NEW YORK.

FROM THE GASTROENTEROLOGICAL SERVICE OF THE MONTEFIORE HOME AND HOSPITAL.

Lavage is a common therapeutic measure in the primary affections of the gastrointestinal canal. In febrile and toxic states, as in pneumonia or postoperative conditions, particularly in abdominal surgery, the functions of the gastrointestinal tract frequently become perverted, abdominal distension and vomiting due to gastrointestinal paresis may become marked and lavage is almost always followed by some relief. Some of the systemic and metabolic disorders as arteriosclerosis, chronic nephritis, chronic lead-poisoning, diabetes, and gout are accompanied by gastrointestinal sluggishness. A course of lavages will stimulate the gastric mucosa, improve appetite, and aid digestion.

The performance of lavage is no pleasant task to the operator nor an act of comfort to the patient. The preparations and procedure generally employed may briefly be described as follows: The patient is seated and draped. A basin of cold water contains the long and stiff stomach tube. A pail on the floor receives the return flow. The operator back of the patient, and holding the latter's jaws apart, introduces the stomach-tube, after which the assistant, or, with great difficulty, the operator himself, delivers water from some pitcher. The psychic effect

alone is apt to usher in the patient feelings of fear and disgust. Besides, the passage of the stomach-tube and its stay in the stomach usually causes nausea, gagging, regurgitation, and, to the very sick, exhaustion. Furthermore, the patient being in the erect posture the return flow must assume an uphill

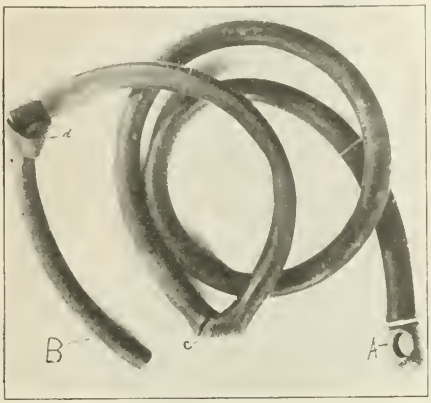

FIG. 1.—The Modified Stomach-Tube. A—Metallic tip. B—Soft and collapsible tubing. The kink c and the knot d show its collapsibility.

direction—against gravity. The stringy mucus and undigested large particles of food, therefore, mostly remain in the stomach. As the ordinary stomach-tube cannot be retained any longer than a few minutes, lavage, therefore, is usually performed very rapidly, clumsily, and often ineffectively. At the end, the patient feels as if he had undergone an ordeal, returns home relating to his friends the horrors of "stomach-pumping" as he calls it. The operator, on the other hand, often stops to reflect upon the therapeutic value of such lavages. As a matter of fact, a good many physicians believe the beneficial effects of a lavage, if any, are altogether psychic.

In the MEDICAL RECORD in the issue of September 27, 1913, I described the modified stomach-tube tending to lessen the difficulties experienced in the passage of the ordinary one. I described also a gastric glass bulb facilitating the extraction and collection of test meals and adaptable for lavage at the bedside or at the home of the patient. In this communication I desire to describe a simplified and speedy method of lavage when performed at the physician's office or in the hospital ward, possessing none of the objectionable features enumerated above. It will be appreciated, particularly, by those who will have occasion to use it often. It is best employed in conjunction with the modified stomach-tube. The outfit consists of:

(A) The modified stomach-tube. For its description and technique the reader is referred to the original communication. In lavage, however, I am using another form of a weighted tube which is being passed and tolerated with still greater ease than the one I use in extraction of test-meals. Its introduction is accomplished in the same manner as the original without using a stylet.

(B) Two graduated irrigating jars B and B′ placed about three feet above the patient, each of 1000 c.c. capacity with outlets at the bottom; B contains an alkaline irrigating solution and B′ a stimulating one, such as silver nitrate 1:10000 (Fig. 2).

(C) Two lengths of rubber tubing C and C′ (Fig. 2) suspended from cocks of the irrigating jars B and B′ respectively, the lower ends of which reach about one foot below the level of the patient when in recumbent posture and are connected to the two upright limbs F and G of

(D) A double-cock glass piece (Figs. 3 and 4) consisting of a stem E, three short limbs F, G, H, and two cocks X and Y. The stop-cock X is double bored so that it may form or sever the communication between F and E, G and E, or closing F, G from E (Fig. 3). The stop-cock Y has a 5/16 inch bore to allow the free passage of mucus and large particles of undigested food. The limb H communicates with the outer end of the stomach-tube by means of rubber tubing one foot long. The irrigating jars, tubing and the double-cock glass piece are permanently fastened to one another by means of adhesive plaster and can be easily carried from ward to ward in some box or basket.

*Procedure.*—The irrigating jars are filled with their respective solution. The modified stomach-tube is introduced in the manner as described in the original communication after which the patient assumes the recumbent posture. The operator connects tubing F to the outer end of the stomach-tube supporting the latter with the right hand and manipulates the stop cocks with the left one. On closing cock Y and opening X, the solution in B will flow out through C, G, X, E and H into the stomach (Fig. 3, B). The operator takes the read-

FIG. 2.—Lavage BB′, irrigating jars; CC′, rubber tubing; D, double-cock glass piece; A, outer end of the stomach-tube, communicating with tubing H; I, receptacle for the return flow. The patient in the recumbent posture, undraped, reads a newspaper during lavage, showing how little disturbed he is by the lavage.

ing and when a quantity of 300 c.c. has thus passed through he closes cock X (Fig. 4, A). As the modified stomach-tube can be retained a considerable length of time without any distress to the patient, the water, therefore, is left in the stomach a few minutes during which time the patient turns him-

self from side to side, thus allowing the thorough bathing of the whole gastric mucosa. Then on opening cock Y the return flow will start by means of siphoning through H, E, and Y (Fig. 4, B) into some receptacle on the floor (Fig. 2, 1). This is repeated a few times in a single lavage, beginning

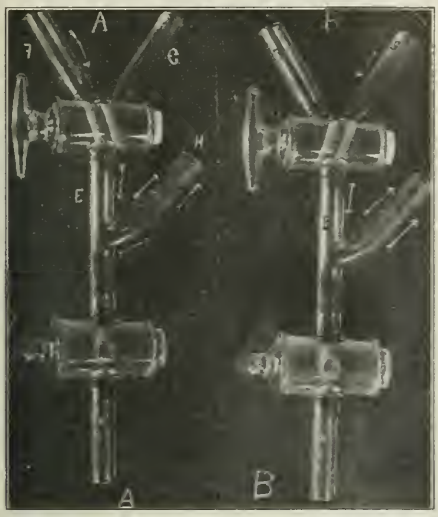

Fig. 3.—The double-cock glass piece for lavage. (Eimer & Amend, N. Y.) A—Cock Y closed, X communicating with F and E, arrows indicate direction of the flow of the irrigating solutions. B—Cock X communicating with G.

with the alkaline solution and ending with the stimulating one in the bottles B and B' respectively.

The design of the double-cock glass piece oc-

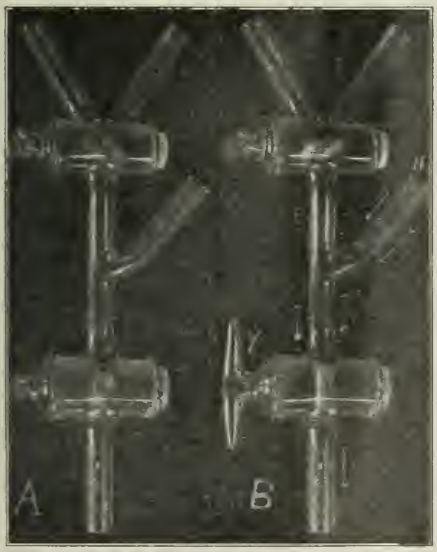

Fig. 4.—A—Cocks X and Y closed, F, G and E discommunicating. B—Cock Y opened, and return flow passes through H, E and Y as indicated by the arrows.

curred to me after Dr. A. Bassler was so generous in demonstrating to me his method of lavage by means of a specially constructed glass-tube embodying to some degree the principle of the double-cock glass-tube which, however, possesses only some minor advantage over the method generally employed. I am indebted to him also for the suggestion of the use of two irrigating solutions as well as many other invaluable suggestions for which I desire to express my thanks.

The double-cock glass piece is time saving, lessens work and renders assistance unnecessary. The patient need not be draped, as he neither gags, coughs, nor vomits, but lies quietly in the recumbent posture in which position the return flow assumes no up-hill direction, and hence, mucus or large particles of undigested food pass out readily. The stream of the water running into the stomach can be easily regulated by the stop-cock—highly desirable in an easily irritable stomach. A lavage by this method is least discomforting and most effective.

I desire to express my obligations to Dr. S. Wachsmann, Medical Director, Montefiore Home and Hospital, whose suggestions have greatly guided me in my researches in gastroenterology.

Gun Hill Road, Two Hundred-and-Tenth Street.

## CASE ILLUSTRATING THE "FACTOR OF SAFETY" IN LUNG TISSUE AND PULSE PRESSURE AS A PROGNOSTIC SIGN.*

By G. H. SEXSMITH, M.D.,
Bayonne, N. J.
Director of the Bayonne Tuberculosis Clinic,
and
M. I. MARSHAK, Ph.G., M.D.,
Bayonne, N. J.
Attending Physician to the Bayonne Tuberculosis Clinic.

THERE has lately been quite some discussion about the "Factor of Safety" or "the excess of available physiological power of organs above what is normally called into play." This excess of power seems to be especially high in the lungs. Courmont has shown that life can still be prolonged if one-fourth of the lung capacity is active, and lately reports from the Laennec Hospital of Paris seem to show that with even one-sixth of the lung capacity, life may be retained.† To illustrate, we would like to cite the following case:

Case.—February 14, 1913.—E. Q., age 17; occupation, clerk; family history, negative; previous history, negative; was long-distance runner. Present history: Three months ago caught "cold" which has persisted to present time; has pain in left side; no chills; has fever; has night sweats; slight cough; little expectoration; digestion, good; appetite, good; bowels, regular. Examination: Temperature, 99.2°; pulse, 120; respiration, 40; weight, 120. Three months ago, when in training, weighed 147. Blood pressure, 105; pulse pressure 5; Von Pirquet reaction, marked. Sputum: numerous tubercle bacilli. On inspection: anemic; phthisical type chest; pupils irregularly dilated; right side lags; supra- and infraclavicular spaces depressed. On palpation: right side lags. Vocal fremetus very much increased on the right side posteriorly, also along a strip about two inches wide to the left of the spinal column. On percussion: right side marked dullness from apex to base posteriorly, also marked dullness along a strip two inches wide to left of spinal column. On auscultation: bronchial breathing, bronchophony and whispering; bronchophony present over dull area. Râles over left lower apex posteriorly. Right middle apex—râles with bronchovesicular breathing. We thought the strip to the left of the spinal column was due to the reflection of the signs on the right side. Heart, normal; arteries, nonpalpable.

March 9, 1913, the patient came back feeling fine; had gained weight; looked healthy. Although he walked to the clinic, about one-half mile from his home at a rather fast pace, he showed no dyspnea.

*Read before the Hudson County Medical Association, October 2, 1913.

†*Journal A. M. A.*, June 7, 1913.

He had slept out of doors since last seen and had followed the hygienic regimen we prescribed carefully. Pulse, 119; respiration, 30; temperature, 980; weight, 124¾.

The right side was still consolidated posteriorly; the left side posteriorly; flatness to the angle of the scapula. Apex of left lower lobe, dullness with râles and bronchovesicular breathing. Anteriorly—apex of left upper lobe, dullness with râles and bronchovesicular breathing; flatness on left to nipple; heart pushed entirely to right of sternum, apex felt in intercostal angle. Blood pressure, 110. Pulse pressure, 19. Diagnosis of fluid made; 6 ounces of serous fluid were removed a few days later with no affect on absorption. Later 2 quarts were removed. No ill effect after removal.

April 12, 1913, heart still to right of sternum. Fluid to ninth interspace on left posterior. Above that, pneumothorax; left lung collapsed. Could get a "lung-fistula" sound over first interspace below the junction of inner and middle third of the clavicle. Right lung posteriorly, dullness apex to base; anteriorly, normal; right middle apex hidden by heart sounds. X-ray taken April 15, 1913, by Dr. H. Axford, showed pneumothorax on the left side with collapsed lung, heart to right of sternum. Right lung: *x*-ray, taken with patient on back, showed various areas of consolidation with areas of normal tissue. This plate was shown to Dr. Quimby of the New York Polyclinic, who was kind enough to help us read it, and who said it was one of the best lung plates he had ever seen.

April 26, 1913, the heart still to right of sternum; fluid on left side to the angle of the scapula, pneumothorax above that; left lung still collapsed, "lung-fistula" sound same as before; dullness still present over right lung posteriorly. Weight, 120¼. Temperature, 100°. Pulse, 112. Respiration, 36. June 7, 1913, patient somewhat cyanotic. Right side posteriorly markedly enlarged over left. Dullness over that side gone. Fluid to ninth interspace on the right side. Area of dullness, bronchial breathing, bronchophony, whispering bronchophony and râles, size of a silver dollar in right lower apex. Left side: fluid to spine of scapula. No pneumothorax. Left lung above compressed area seemed normal. Anteriorly: Heart plainly seen pulsating to right of sternum. Lung tissue of right lung anteriorly seemed normal. Fluid on left side front to third interspace. Lung above compressed area seemed normal. Complained of feeling very tired; coughing and expectorating profusely. Weight, 121¼. Temperature, 102°. Pulse, 139. Respiration, 36. Some of the fluid removed three days later proved to be purulosanguineous. Examination showed diplococci. No tubercle bacilli. Next day two quarts of fluid were withdrawn and 2 ounces of a 2 per cent. solution formalin in glycerine were injected into the plural cavity.

Fig. 1.—Skiagram, with the patient lying down.

June 21, 1913, patient felt weak; marked dyspnea. Temperature, 102°. Pulse, 120. Respiration, 50. Weight, 120. Fluid on left side posteriorly up to the angle of scapula. Up to the nipple anteriorly. Lung above the fluid anteriorly gave signs of marked consolidation. At second intercostal space one inch to left of sternal margin, could make out "lung-fistula" sound. Right side, posteriorly, fluid to ninth interspace. Right lower apex still consolidated with râles. Anteriorly: heart still to right of sternum; a marked systolic murmur. Lung in front normal. Patient complained of weakness, cough and expectoration. This expectorated material patient said was similar to material which had been withdrawn from chest. This material upon examination was found to be purulosanguineous, full of diplococci with no tubercle bacilli. This proved that there was a "lung-fistula" present.

Fig. 2.—Skiagram, with the patient sitting up.

*Recapitulation.*—We consider that this case shows very well "the factor of safety," because on having the left chest practically full of fluid, while the right side was consolidated posteriorly and was further hampered by the displaced heart, the patient walked one-half mile to the clinic at a brisk gate and showed no dyspnea. Secondly, on April 15, 1913, having an absolutely collapsed left lung, with some consolidation in the right lung, with the heart to the right of the sternum, the patient ran up two flights of stairs to the *x*-ray room as fast as we did and showed less dyspnea; and, thirdly, we have seen him as far as two miles from home walking briskly and could not make him stop taking long walks as long as he felt well; in fact, he kept taking these walks until the latter part of May. During all that time he had probably only one-fourth of his lung tissue physiologically active. We would like to add this case to the great number reported, showing that low blood pressure, and especially low pulse pressure, indicates poor resistance and is a good prognostic sign.

## A EUROPEAN STUDY TOUR.

By RICHARD KOVACS, M.D.,
NEW YORK.

Study trips by professional men are coming more and more into vogue. The idea of organizing a travel-study by American physicians came from Germany, where an organization for this purpose has been in existence for the past fifteen years. This body arranges study trips for its members once or twice a year. It undertook its first American excursion a year ago last fall in connection with the International Congress of Hygiene and Demography in Washington. More than 200 members coming from all parts of the European continent visited the medical institutions of New York, Philadelphia, Baltimore, Washington, Chicago, Montreal, Toronto, Boston, etc. The success of the European party showed American physicians the advantages of a well-managed study tour. The tourists were received with exceptional courtesy by the government and by local authorities and medical societies. Everything pertaining to medical matters and sightseeing was so carefully provided for in advance that those unfamiliar with the language of the country visited did not feel this disadvantage.

Shortly after the German study tour returned to Europe, several New York physicians met and decided to form a similar association. As a first attempt a tour was organized in connection with the then coming Seventeenth International Congress in London, August, 1913. The plan included visits to most of the important capitals and health resorts of Europe, before the Congress was to be attended. Sixty-eight participants sailed from New York on July 3 on the North German Lloyd S. S. "Bremen." The list of members included Major Louis Livingston Seaman, Dr. Fred H. Albee, Dr. William De Garmo and Dr. S. Breitenfeld, of New York; Dr. Howard Van Rensselaer, of Albany; Dr. Edward B. Heckel, of Pittsburg; Dr. John Punton, of Kansas City; Major Henry Page, U. S. A.; Dr. Winslow Anderson, of San Francisco; J. F. Percy, of Galesburg, Ill.; Dr. J. P. Lord, of Omaha; Dr. A. J. Crowell, of Charlotte, N. C.; Drs. H. P. and S. P. Collings, of Hot Springs, Ark.; and others. The nine-day voyage was full of interest. The large dining hall was transformed into a lecture room in which professional lectures were given in the morning, while on certain afternoons or evenings the passengers of the ship were invited to listen to lectures of educational and general interest. All of the latter were illustrated by stereopticon views. Among the subjects treated were "African Sleeping Sickness," and "Big Game Hunting in Africa," by Dr. Louis Livingston Seaman; "Bone Transplantation," by Dr. Fred H. Albee; "Medical Experience in the Arctic," by Dr. Harold H. Foss; "Ten Years as Doctor Amongst Savage Tribes," by Major Henry Page, U. S. A., and "The Newer Mission of the Doctor and Hospital," by Dr. John Punton. With plenty of time at our disposal it naturally followed that the discussions were more lively and more detailed than we are accustomed to hear on land. At the popular lectures the dining saloon and its gallery were crowded to their utmost capacity.

The American Physicians in Berlin. The picture was taken in front of the Kaiser Wilhelm Akademie. The officer is Prof. Dr. von Schjerning, Chief Surgeon of the German Army.

Paris was the first city visited. We arrived just before the French national holiday, July 14. Our party was invited to visit the splendid "Revue" at Longchamps, and the same afternoon we were guests of Ambassador and Mrs. Herrick at a garden party. Three days were spent in inspecting hospitals and other institutions of medical interest. At the French Academy of Medicine a cordial reception was tendered us. At the Faculty of Medicine some of the examinations for the degrees in medicine were witnessed by our party. Both professors and students are required to appear in the ornate robes worn at these occasions since ancient times. The anatomical museum of the University is one of the oldest in Europe; the dissecting rooms are ample; 500 students have room and material enough for simultaneous work.

The hospitals present a contrast which one does not see in America. Opposite the new Hôpi-

tal de La Pitie, an entirely modern structure, is the immense "Hospice de la Salpétrière," converted from a saltpeter factory into a general hospital by order of Louis XIV. This institution has nearly 4,000 beds. The Hôtel Dieu is still older. It is a general hospital on the Island of the Cités. Here Reclus, the father of local anesthesia, gave us a very interesting demonstration. The visits to these hospitals conveyed the impression that modern American hospitals have very little to learn from the similar French institutions, and that in all the old buildings unhygienic conditions actually exist which would not be tolerated in any American community.

On the other hand the teachers and their clinics are admirable. At the Hôpital Cochin Professors Chauffard and Widal held clinics on internal medicine. At the Clinique Tarnier Professor Bar demonstrated the system of this obstetrical clinic. At the Hôpital Broca the famous ambidextrous gynecologist, Pozzi, performed one of his marvelous, rapid and skilful operations. His clinic is radically different from that of any other hospital. The corridors and wards are transformed into large picture galleries by fresco paintings, which are washable and therefore hygienic. These are intended to make the surroundings of the patients cheerful and pleasant. We visited the Pasteur Institute and Hospital and stood with deep reverence before the tomb of the father of modern bacteriology. Our last visit was to the Palais de Justice, to inspect the department of Dr. Bertillon, the famous scientist. Measurements and fingerprints of several colleagues were taken and the index cards signed by Bertillon were obtained as valuable souvenirs.

Munich was the next city visited. Its great, new medical institutions and the beauty of this city of are fully justify the decision made in London to hold the next International Medical Congress there in 1917. The new Munich-Schwabing Hospital has about 1,400 beds, and is an ideal type of a hospital. The university clinics and polyclinics and their splendid teachers have made Munich next in importance to Berlin as a medical center. Friedrich Müller, Kraepelin, Döderlein, and Hess are well known names even in America. The members of our party were delighted to meet these illustrious scientists at a "Gemüthlicher Bierabend" at the Austellungs Park.

Three days were spent in Vienna, the birthplace of modern clinical medicine. The 300-year-old "Allgemeine Krankenhaus," consecrated by the work of men like Auenbrugger, Hyrtl, Rokitansky, Billroth and Nothnagel was visited with due reverence. The buildings are unsightly, antiquated and unhygienic. Unfortunate political conditions in Austria greatly hinder the construction of new clinics and hospitals. Present hospital accommodations are entirely inadequate for the needs of the city, with its large population and the great influx of patients not only from all over the continent of Europe, but also from the nearby Orient. Political conditions also interfere with the task of getting men of proper calibre to fill professional vacancies at the university. Nevertheless, Vienna is still one of the great medical centers of the world, and the large material of the "Allgemeine Krankenhaus" furnishes unexcelled opportunities, especially for postgraduate medical instruction. It is very popular with American physicians. The well-managed American Medical Association of Vienna arranges for special courses given in English.

A number of excellent clinics were given by the surgeon, Von Eiselsberg, the dermatologist Riehl, the gynecologist Wertheim, the surgeon Hochenegg, the neurologist Marburg, the pediatrist Van Pirquet, the laryngologist Chiari, and others. The great Pathological Anatomical Museum is under the direction of Hofrat Weichselbaum. Physicians and visitors of the Krankenhaus are invited to the daily postmortems at the Pathological Institute. On the desk there are "death cards," their number corresponding with those on tags attached to the bodies. The cards contain salient facts such as clinical diagnosis, the number of the ward, and the name of the clinicians. A postmortem is made in every case of death in the hospital, a procedure of inestimable value to the value of clinicians. The next morning we saw the "Steinhof," a State Insane Asylum in the suburb of Huetteldorf. It is a most modern institution, perhaps the best equipped in the world. It was built at an expense of thirty million kronen (6,000,000). Sixty large buildings accommodate 4,000 patients. A church and a theatre form part of the institution. The following Sunday afternoon the tourists were guests of the nearby city of Baden, a well-known watering place, and on the day following the ladies were invited to a tea in the park of the famous Lichtenstein gallery as guests of Prince Lichtenstein. The physicians of Vienna cordially welcomed our tourists at a dinner at the Adria exposition in the famous "Prater." Professor Lorenz, the well known orthopedist, acted as toastmaster and chairman. During the following days the famous Bohemian health resorts of Karlsbad and Marienbad were visited, and a short trip was also made to Joachimsthal, where radium is obtained from mines controlled by the Austrian government.

In the model city of Dresden two days were spent seeing modern hospitals and art galleries with their treasures. Visits were also made to the Crematorium in Tolkvitz and the city slaughter house and filtering plants. The city of Dresden gave us a splendid reception and our colleagues of Dresden a luncheon, where Geheimrat Prof. Renk, president of the Royal Health Board, presided.

Berlin is to-day the leading medical center. Research work and clinical teaching are going on in new, splendidly equipped city, state, and imperial hospitals, laboratories and other institutions. As elsewhere in the continent, the men who follow the university career receive ample salaries, making practice unnecessary. The Charités Krankenhaus consists of a number of modern clinical institutions accommodating about 2,000 medical students and at least as many physicians. The teaching staff includes such leaders of medical thought as the internists Wilhelm His, the successor of Leyden, and Friedrich Kraus, successor of Gerhart; Johannes Orth, the pathologist, a worthy successor of the great Virchow; Bumm and Franz, the gynecologists, Heubner, the pediatrist, and Bonhoeffer, the neuro-psychiatrist. The Rudolf Virchow Krankenhaus with its 2,000 beds and sixty-seven pavilions is an appropriate memorial to the illustrious scientist after whom it is named. Nearby is the Robert Koch Institution, which was really the Royal Institute for Infectious Diseases, and which was named later after its first famous director. This institution is amply provided for by the government and is conducting the scientific investigation of infectious diseases. It also serves as a central consulting station for the medical department of the Prussian Ministry

of Education. Another new and unique institution is the Kaiserin Augusta Victoria Anstalt in Charlottenburg, which was founded in 1909 for the purpose of reducing the mortality among nursing infants. It is the central bureau for the entire German Empire in regard to practical and scientific information relating to pregnant women, their care before confinement, hygienic rules for confinement, the care of nursing infants, the care of artificial food, and the chemical and bacteriological examinations of milk, in fact, everything that may advance the health and development of the new-born babe or the care of a weak child.

A number of similar central institutions dealing with matters of general health and welfare are also situated in Berlin. Their work is wonderfully organized and efficient. Much of the success of our study tour was due to a central institution of this kind. This is the Kaiserin Friedrich Haus, the official seat of the Central Committee for Postgraduate Medical Education, of which Prof. Waldeyer is president. It is under the direction of the Prussian Ministry of Public Instruction and provides for regular annual gratuitous postgraduate and clinical lectures for physicians in forty-eight large cities of the German Empire. In the Kaiserin Friedrich Haus we find clinical instruction rooms for physicians, collections of objects aiding in medical instruction, a permanent exposition of products of medicotechnical industry, and a bureau of information and organization. Through its local committees the postgraduate committee, under its able and energetic secretary-general, Professor Kutner, arranged for the reception and medical program of the American study tour in a marvelous way all over Europe. The account of the stay in Berlin would be incomplete without mention of the reception at the Kaiser Wilhelm's Akademie, the training school for army medical officers, by his Excellency, Prof. A. Von Schjerning, the chief surgeon of the German Army, who is also the physician of the German Emperor. One evening the physicians of Berlin gave a reception and a concert at the Austellungs Park. The performers at this concert were all German physicians or their wives. Professor Waldeyer was chairman and the official speakers among whom was the distinguished neurologist, Professor Moll, gave voice to their respect for American medicine and the gratitude felt by German physicians for the splendid reception in America given to last year's German Study Tour.

The birthplace of the great German poet and scientist, Johann Wolfgang Goethe, Frankfort on the Main, was the next stop. The modern large hospitals have a staff of excellent medical men, who are to become teachers in the new University of Frankfort, which is about to be established. Prof. Carl von Noorden recently decided to leave his chair in Vienna and return to Frankfort. However, the greatest attraction for medical men, and the one which put Frankfort in the center of both medical and popular interest throughout the world, are the Ehrlich Laboratories at the Royal Therapeutic Institute. Professor Ehrlich received the Americans. He showed the travelers his laboratories, the Mecca of scientists from all over the world. He explained some of the newer drugs and experiments used with success in the combat of hitherto unconquerable diseases of parasitic infectious origin.

Within a short distance from Franfort there are a number of world-famous health resorts. Three of the "Taunus-bäder" were visited. Bad Nauheim belongs to the Hessian Grand Ducal Government, which recently erected a number of most beautiful modern buildings and bath houses. Here we observed the details of the famous Nauheim treatment for chronic affections of the heart. Homburg has a number of powerful mineral waters, especially for catarrhal and anemic conditions. It belongs to Prussia. At the time of our visit the German Empress was taking the cure there. The Kurdirektor, Count Zeppelin, a nephew of the famous air-conqueror, of the same name, provided a special "air ride" for about fifteen members of the American party, which they described as providing an entirely safe and delightful sensation. Wiesbaden is the oldest and largest of the Taunus baths. Even Pliny mentions the warm springs of Mahincum (Wiesbaden), where the fourteenth legion erected a castle. Among the many well-equipped institutions the municipal Kaiser-Friedrich Bad, deserves special mention. It was completed two years ago at a cost of 4,000,000 marks, and is absolutely the last word in modern hydrotherapeutic institutions.

In all these places our party was overwhelmed by the cordiality of the reception and the number of luncheons and dinners given in our honor. But this is not surprising, for the majority of well-to-do patients in these resorts are Americans. What wealth for domestic consumption and what benefit for millions of our less fortunate citizens, if some of our American health resorts, possessing undoubtedly all the healing agencies of European resorts were to be equipped and managed with the same vigor and same success as these!

From Wiesbaden the tourists took the beautiful Rhine trip down to Cologne, and here and in Düsseldorf, nearby, we visited the two Academies of Practical Medicine. These are new institutions which are organized in connection with the Central Committee for Postgraduate Medical Education at Berlin. Being in close connection with splendidly equipped large hospitals and possessing a staff of excellent teachers, the purpose of these academies is manifold. They give the medical candidate an opportunity after he has finished his State examination to put in his required year of practice before he receives his M.D. and the license to practice. They afford a place for the young physicians to do special work in preparing to become specialists. They conduct advanced courses, such as those in school hygiene. They also give courses for male and female nurses. Beautifully situated on the outskirts of the city, the picturesque buildings of the academies gave the impression of a college, and not that of a hospital. Their courses are gratis to Germans and foreigners alike.

The last city of medical interest on the Continent was Brussells, where the Solvay Institutes of the University and the well-equipped private clinic of Professor Depage were visited. Two days later, on the eve of the opening of the Seventeenth International Medical Congress in London the official program of the study tour was completed. The members now attended the various sections of the great Congress.

Much was seen in Europe and many suggestions were received, together with many ideas for improvement of conditions over here. But in general we can be justly proud of our American medical institutions, which were founded and equipped with practically no official help, and many of which

have achieved world-wide fame and recognition by their work. Briefly summed up the situation is as follows: The scientific pursuit of knowledge upon the Continent of Europe is subsidized. Conditions for research work are made infinitely more easy than in America. The social position and the financial benefits accruing to a man of scientific worth are far better there than with us. As a direct result of this system we see that in the main, pathology, clinical medicine, pediatrics, neurology, pharmacology, and dermatology are better taught abroad. The teachers have good salaries and can devote themselves to the matter at hand without regard to the ever-present question of our country—will it pay?

On the other hand, the Americans who go abroad quickly realize that in surgery we are far ahead of the average European clinic. There are several brilliant exceptions to this statement. Trained nursing as we know it simply does not exist abroad except in certain isolated instances. If we go to Europe with open minds and disregard the points of their system which we consider weak we will find that there is a tremendous amount of easily available knowledge placed at our disposal.

236 East Sixty-ninth Street.

## THE PHYSICAL CONDITION OF RETARDED SCHOOL CHILDREN.*

By S. JOSEPHINE BAKER, M.D.,

NEW YORK.

DIRECTOR OF CHILD HYGIENE, DEPARTMENT OF HEALTH, NEW YORK CITY.

Of all the problems presented in regard to school medical inspection and the hygiene of the school and school child none has been more complex than that concerning the relation between physical ill health and school progress. Owing to the lack of standardization of methods of promotion all studies made of this subject have in large degree been unsatisfactory and unconvincing. The notable contribution made to this subject by Leonard Ayers, for instance, gave as a statistical conclusion the statement that school children with defective vision progressed as rapidly in their school advancement as the average child, yet it is the common impression received by those of us who are in active contact with these children that defective vision handicaps a child in its school progress and is a frequent cause of retardation. Promotion seems to depend upon such a wide range of variable factors that scientific conclusions as to the contributing cause of ill health cannot be drawn or applied to the problem as a whole. The retarded school child is regarded as a pedagogical problem of the greatest magnitude. In the elementary public schools of New York City there were 124,398 over-age children in the grades, or 21 per cent. out of a total registration of 579,728, according to the annual report of the City Superintendent of Schools for the year ending July 31, 1912. The same report states that "The problem of over age may be grappled with in three ways, (1) by way of organization and classification, (2) by modifications in the curriculum, and (3) by improved teaching." Two forms of practical methods are outlined, (1) special classes, and (2) the so-called double time plan. Here the problem is considered wholly in its pedagogical aspects. There can be no question, however, that it is the duty of the school hygienist to determine what relation, if any, physical ill health has as an influence in non-promotion and to contribute a program for dealing with this particular factor. Such a study was made during the period between February and July of this year by specially selected, interested and efficient physicians and nurses of the Division of Child Hygiene of the Department of Health in the New York City Public Schools.

*Read at the Fourth International Congress of School Hygiene, August 28, 1913.

Table I.

| | |
|---|---|
| Number of children examined | 1,541 |
| Number found with physical defects | 1,202 |
| Of which:— | |
| In "D" classes | 26 |
| In "E" classes | 107 |
| Over-age in grades from 1-A to 8-B | 1,069 |
| | 1,202 |

Six out of the twelve schools selected have "D" and "E" classes. The remainder have retarded and over-age children placed throughout the regular grades.

"D" classes are for pupils who are preparing to take examinations for employment certificates.

"E" classes are for over-age children to endeavor to make up for grades lost.

For the purpose of this study four groups of schools in New York City were selected—four in the Borough of Manhattan, three in the Borough of the Bronx, three in the borough of Brooklyn, and two in the Borough of Queens—a total of twelve schools. The selection was made on the basis of the average school, without a preponderating attendance of children of any one nationality and with a view to obtaining the best possible cooperation of the principals and teachers. Interested and efficient physicians and nurses were detailed for the work of examination and follow-up visits to the homes. Three sets of record cards were used, one to contain the child's school record and the teacher's opinion as to causes of retardation, the second for data of the physical examination, treatment provided, and result of treatment as shown by physical reexamination, the third for social, sanitary, and hygienic conditions of the home.

Table II.

Number of retarded children with physical defects..... 1,202

| Ages | Number | Per Cent. |
|---|---|---|
| 6 years | 4 | 0.3 |
| 7 years | 20 | 1.7 |
| 8 years | 57 | 4.7 |
| 9 years | 94 | 7.8 |
| 10 years | 121 | 10.1 |
| 11 years | 153 | 12.7 |
| 12 years | 215 | 17.9 |
| 13 years | 223 | 18.6 |
| 14 years | 218 | 18.1 |
| 15 years | 77 | 6.5 |
| 16 years | 15 | 1.2 |
| 17 years | 2 | .2 |
| Not given | 3 | .2 |

In six of the twelve schools special classes designated as "E" are maintained for over-age pupils who are unable to maintain their proper school grade; other classes designated as "D" are maintained in two of the selected schools for pupils who need extra preparation in order that they may at the age of fourteen years complete the 5B grade legally essential for obtaining employment certificates. (The normal age of the 5B grade child is given by the Department of Education as ten to twelve years.) Of the children found with physical defects, 26 were from classes "D" and 107 from classes "E." The remaining 1,069 children were selected from over-age children in the grades where no special classes for them were provided.

In all, 1,541 children were physically examined and kept under supervision. None of these children were true mental defectives, and inability to speak the English language was not a factor in the cases examined nor the cause of retardation. In the instances enumerated under "foreigner—recent arrival" in Table IX previous lack of education was the retarding influence. The ages of the children ranged from 6 to 17 years, the greater number of instances of retardation being found at 13 years, with a total of 223, or 18.6 per cent., the number at each age increasing up to this point in rapid progression and declining afterward with equal rapidity.

TABLE III.

| Nativity | Number | Per Cent. |
|---|---|---|
| United States | 646 | 53.7 |
| Russia | 324 | 26.9 |
| Italy | 114 | 9.5 |
| Austria | 32 | 2.6 |
| England | 21 | 1.7 |
| Germany | 20 | 1.6 |
| France | 12 | 9 |
| Hungary | 6 | 3.1 |
| Roumania | 3 | |
| Poland | 2 | |
| Asia | 2 | |
| Spain | 1 | |
| Gallicia | 1 | |
| Sweden | 1 | |
| South America | 1 | |
| Not known | 16 | |

TABLE IV.
NON-PROMOTIONS

| Times Left Back | Pupils With Physical Defects | Per Cent. | Total Number Non-Promotions |
|---|---|---|---|
| 0 | 218 | 18.1 | 0 |
| 1 | 245 | 20.4 | 245 |
| 2 | 250 | 20.8 | 500 |
| 3 | 197 | 16.5 | 591 |
| 4 | 123 | 10.3 | 492 |
| 5 | 78 | 6.4 | 390 |
| 6 | 33 | 2.7 | 198 |
| 7 | 14 | 1.2 | 98 |
| 8 | 6 | 0.5 | 48 |
| 9 | 3 | 0.2 | 27 |
| No record | 35 | 2.9 | 0 |
| | 1202 | 100.0 | 2589 |

2.6 per cent. average number of times failed of promotion.

TABLE V.

| | Routine Pyysical Examinations, 1912 | | Special Physical Examinations of Retarded Pupils | |
|---|---|---|---|---|
| Number of children examined | 287,469 | | 1,541 | |
| | Number | Per Cent. | Number | Per Cent. |
| Normal | 80,749 | 27.8 | 158 | 10.2 |
| Teeth defects only | 119,359 | 41.5 | 181 | 11.8 |
| General defects | 87,361 | 30.4 | 1,202 | 78.0 |

The nationality of the children showed a wide compass; 53.7 per cent. having been born in the United States, 26.9 per cent. in Russia, 9.5 per cent. in Italy, the remainder being credited to twelve different countries.

The number of non-promotions is shown in Table IV. For the purpose of this study only the children with general physical defects are considered. The 218 children who had not previously failed of promotion include those who entering school for the first time were over-age for their grade. These 1,202 children had failed of promotion 2,589 times, or an average of 2.6 failures for each child.

Of the 1,541 retarded children examined 1,383, or 89 per cent., were found to have one or more physical defects. This is of particular interest in comparison with the 71.1 per cent. of physical defectives found in the regular routine examination of all pupils. The fact of particular importance in this broad classifiction as shown in Table V is the preponderance of the general physical defects occurring in the retarded children; 78 per cent., as contrasted with 30.4 per cent. in the children examined in the regular routine. The children with defective teeth as the only physical defect are contrasted in inverse ratio, showing 11.8 per cent. for the retarded children to 41.5 for the children as a whole.

TABLE VI.

| | Regular Routine Physical Examinations Made During 1912 | | Special Physical Examination of Retarded School Children | |
|---|---|---|---|---|
| No. of children examined | 287,469 | | 1,541 | |
| No. found with physical defects | 206,720—71.9 per cent. | | 1,383—89.8 per cent. | |
| No. of defects found | 226,639 | | 2,986 | |
| Nature of Defect | Number | Per Cent. | Number | Per Cent. |
| Anemia | * | * | 355 | 23 |
| Malnutrition | 8,303 | 2.9 | 557 | 36.1 |
| Defective vision | 21,078 | 7.3 | 536 | 34.7 |
| Defective hearing | 1,206 | 0.5 | 47 | 3.0 |
| Defective nasal breathing | 21,931 | 7.6 | 316 | 20.4 |
| Hypertrophied tonsils | 30,021 | 10.4 | 297 | 19.2 |
| Defective teeth | 142,168 | 49.4 | 796 | 51.6 |
| Pulmonary disease | 335 | 0.1 | 47 | 3.0 |
| Cardiac disease | 1,597 | 0.5 | 35 | 2.3 |
| Average number of defects per child | ..... | 1.1 | ..... | 2.5 |

*Not classified.

TABLE VII.

| | Occurring as Only Defect | Associated With Other Defects |
|---|---|---|
| Anemia | 16 | 339 |
| Malnutrition | 44 | 513 |
| Defective vision | 176 | 360 |
| Defective nasal breathing | 62 | 254 |
| Hypertrophied tonsils | 30 | 267 |
| Defective hearing | 3 | 44 |
| Defective teeth | 181 | 615 |
| Total | 512 | 2392 |

The relatively small number of retarded children who were physically normal with the exception of defective teeth offers an interesting field for study as to the significance of dental defects in relation to retardation.

The comparison of the various types of physical defects found, as shown in Table VI, is significant. Malnutrition found in 2.9 per cent. of all school children was found in 36.1 per cent. of the retarded children; anemia in 23 per cent. of the cases. The examination for defective vision was made more thoroughly than has proved practical in the regular routine examination. The refraction of each child was determined. However, as subjective symptoms of eyestrain are regularly ascertained as well as the Snellen test card used in the regular routine examinations, I am of the opinion that the marked difference—34.7 per cent. in the retarded children as compared with 9.3 per cent. in the children as a whole—is not wholly due to the greater care taken in this instance, but rather should be considered as a definite cause of the retardation, and, therefore, a predominant symptom in children selected because of inability to progress in their studies. The striking contrast between 20.4 per cent. of instances of defective nasal breathing in the retarded children and 7.6 per cent. in the regular group is more marked than that of the respective occurrence of 19.2 per cent. and 10.4 per cent. of hypertrophied tonsils. Defective hearing in 3 per cent. of the cases is an obvious cause of retardation and the contrast with .5 per cent. in the children at large calls for no fur-

ther comment. Pulmonary disease, with the ratio of 3 per cent. to .1 per cent., and cardiac disease in the contrasting occurrence of 2.3 per cent. in the retarded and .5 per cent. in all of the children follows the general ratio of the other serious defects. The one exception noted is the relative importance of defective teeth. While they were found to be present in 51.6 per cent. of the retarded children as opposed to 49.4 per cent. in the children of the regular group, they were found mainly in association with other physical defects in the cases studied. The retarded children studied showed an average of 2.5 defects per child, while the children examined in routine show an average of 1.1 defects per child.

The analysis of the conditions of the home, including sanitation, hygiene, and care is offered merely as a general index. Such data, even when compiled by careful investigators, is a matter of relative opinion and is necessarily influenced by the personal point of view. The factors considered were the sanitary and hygienic conditions of the premises and home, family intelligence and care given to the child and the food, hygiene, and rest periods. Classified together they were found to be good in 49.6 per cent., fair in 31.6 per cent., poor in 15.6 per cent., while 3.2 per cent. could not be classified. A special analysis of the same factors in the malnutrition and adenoid and hypertrophied tonsil cases showed much the same general average.

Table VIII.

| STIMULANTS (MALNUTRITION CASES)* | |
|---|---|
| Number of pupils | 647 |
| Stimulants used | 304—47 per cent. |
| Stimulants not used | 343—53 per cent. |
| Coffee used by 258 pupils | 39.8 per cent. |
| Tea used by 93 pupils | 14.3 per cent. |
| Beer used by 20 pupils | 3.09 per cent. |
| Wine used by 3 pupils | .46 per cent. |

*Including the anemia cases of marked type.

Table VIII is of interest as showing the use of stimulating beverages by the children suffering from malnutrition. The limited use of wine or beer, as shown in this group, can hardly be considered as a contributing factor in these cases, while the use of coffee by 39.8 per cent. and tea by 14.3 per cent. may readily be conceived as having some bearing on the etiology of the disturbed nutrition.

Table IX.

REASONS FOR RETARDATION

Of 1202 pupils with physical defects, the records of 218 gave no information unon which causes for retardation might be based. The causes ascribed for the remaining 984 pupils are berewith given, it being understood tbat in many cases a pupil bad several factors checked up against him:

| | | | Per Cent. |
|---|---|---|---|
| 1. | Mentality | 232 | 23.6 |
| 2. | Foreigner (recent arrival) | 115 | 11.7 |
| 3. | Late start | 191 | 19.4 |
| 4. | Personal illness | 270 | 27.4 |
| 5. | Illness at bome | 25 | 2.6 |
| 6. | Quarantine | 24 | 2.5 |
| 7. | Conduct (including truancy) | 55 | 5.6 |
| 8. | Absence (not specially defined) | 81 | 8.2 |
| 9. | Freq ent change in school | 34 | 3.4 |
| 10. | Family illiteracy | 10 | 1.0 |

The assigned causes of retardation in 984 of these physically defective children are given as opinion based upon the factors from the school point of view. Here personal illness as given in 27.4 per cent. of the cases studied is the only definitely given cause that may be considered as bearing upon the physical status of the children examined. No proof can be presented, worthy of acceptance, showing that the children in this group were retarded in their school progress because of the presence of the untreated physical defects discovered. Yet the fact remains that these children who by reason of their retardation must be classified as of subnormal mentality are physically subnormal in a greater degree than the average child. Disregarding the pedagogical aspect of the case, is it not the duty of the school hygienist to definitely focus his attention upon the retarded school children as the class who inevitably, by virtue of their physical disability, must be retarded in future physical resistance and good health in adult life?

33 West Ninety-sixth Street.

## PERSISTENT HICCOUGH.

By FRANCIS H. MEAD, M.D.,

SAN DIEGO, CAL.

PERSISTENT hiccough is often a troublesome condition, and as many remedies are advised for its relief the following experience may be of interest:

Major X., on Nov. 23 was suddenly taken ill in the evening. When I saw him that night he had had a severe chill and was running a temperature of 102.6°. He had previously suffered from a light attack of cerebral apoplexy, had an enlarged prostate with old interstitial nephritis, and a much dilated stomach. With appropriate emunctory remedies, as the symptoms were due to intestinal autoxication, the temperature became normal the next afternoon, and he expressed himself as feeling much better. On the afternoon of Nov. 27 a slight hiccough developed, for which he was in the first place given some peppermint water, with, as the symptoms increased, a sinapism. He was taking only a liquid diet, and there was no question of gastric distention with improper food, as this had been fully relieved. He passed a restless night with much hiccough. This persisting during the day, the next night he received 1/50 of a grain of atropine with morphine hydrochlorate, gr. 1/8 by hypodermic injection. He slept better and there was absence of hiccough for two or three hours, but it was renewed the next morning. I was afraid to wash out his stomach as he was unusued to it and the previous attack of apoplexy made one careful not to let him undergo any great exertion. He was given chloretone gr. iij with urotropin gr. xx every two hours as the urine was alkaline. This had no result. Ringer's mustard treatment was then tried, but also was of no avail. I then gave him ten drops of a saturated solution of menthol in spiritus vini rect., in a little hot water. This was to be repeated every hour if necessary. With the first dose relief was experienced, and after four doses in the first twenty-four hours there has been no recurrence of the hiccough. Dilatation with carbonic acid and the posture treatment I did not try as my patient's condition negatived them.

**Angioma of Synovial Membrane of Elbow.**—Sir Frederic Eve reports the case of a girl aged 11 years,in whom one year and nine months previously the elbow became swollen and painful. The patient was laid up with it for a fortnight. The swelling was attributed to a blow on the part two or three years previously. Since then the elbow has become swollen every few weeks. Present condition: There was a bluish bilobed swelling on the outer side of the head of the radius; the swelling disappeared on raising the arm; after applying an elastic ligature to the upper arm it stood out prominently and the circumference of the limb at the site of the swelling was increased one-quarter inch. The writer drew attention to this condition in 1903, and described two cases of angioma involving only the synovial membrane, and two others implicating also the surrounding muscles. The chief interest of the condition lies in the diagnosis from localized tuberculosis of the synovial membrane. This may usually be made by observing the changes in the swelling induced by alterations of the venous circulation. Angiomata of the synovial membrane often give rise to a good deal of pain, increased by exercise. There may be tenderness, limitation of movement, wasting of muscle, and two of the writer's cases complained of starting of the limb at night.—*Proceedings of the Royal Society of Medicine.*

## RECENT INVESTIGATIONS ON DIPHTHERITIC PARALYSIS.

THE nature of diphtheritic paralysis, its relation to the toxins of the diphtheria bacillus, and the efficacy of the serum treatment in preventing or in relieving this condition, are subjects about which there has been considerable difference of opinion. The idea has prevailed that the antitoxic treatment has not tended to diminish the incidence of paralysis. Nevertheless many French clinicians have extolled the value of massive injections of the specific serum in the treatment of paralyses even long after the disappearance of the initial symptoms of diphtheria. The introduction of the more modern methods in the treatment of diphtheria, particularly the rise of single large doses of antitoxin and the employment of the intravenous method of administration, and the recent announcement by von Behring that certain mixtures of diphtheria toxin and antitoxin are more potent in the treatment of diphtheria than antitoxin alone, place the subject of diphtheritic paralysis in a new light, and suggest many new points of interest regarding the causation and the prevention of this condition.

Professor Paul Römer and Dr. Viereck, working in the Institute of Hygiene and Experimental Therapy of Marburg, of which von Behring is director, have conducted an important series of investigations with reference to the above topics. They publish their results in the *Beiträge zur Klink der Infektionskrankheiten und zur Immunitätsforschung*, Vol. 2, No. 1. First of all they subjected the question of the serum treatment in relation to diphtheritic paralysis to a critical and an experimental analysis. They found that antitoxin in no way favors the onset of paralysis. The apparent increase in the incidence of postdiphtheritic paralysis that has been noted since the introduction of the Behring-Roux serum, is to be attributed to the fact that the mortality from diphtheria having been greatly lowered, many more individuals than hitherto survive to become victims of diphtheritic paralysis. Animal experiments showed that when timely used even small doses of antitoxin serve to prevent the onset of paralysis; the administration of antitoxin within twenty-four hours after the injection of diphtheria toxin either prevents entirely or greatly mitigates the paralysis. The authors were not able, however, to demonstrate any curative influence of the antitoxic serum upon any paralysis that has resulted. The practical conclusions to be derived from this set of experiments are that the early administration of antitoxin is necessary, that the most effective route of injection is the intravenous one, and that sufficient antitoxin, though not necessarily a massive dose, should be given, in order that the possibility of an ensuing paralysis should be minimized. The treatment most effective in combating the acute diphtheritic infection is therefore the one that is most potent in preventing the secondary paralyses.

The next line of investigation conducted by Römer and Viereck was into the nature of diphtheritic paralysis and its relation to the diphtheria toxins. Clinically, diphtheritic paralysis, at any rate in its early stages, is a process that is localized in the group of muscles near the seat of the original disease, as in the soft palate, pharynx, and larynx. Experiments on guinea-pigs show that the first sign of paralysis corresponds to the site of injection of the diphtheria toxin. Generalized paralysis follows later. The next step served to determine what numerical relationship, if any, exists between the acute fatal dose and the paralyzing dose of various preparations of diphtheria toxin. Five such preparations were tested. In specimen I the paralyzing dose was found to be one-seventh of the minimum fatal dose. In specimen II the paralyzing dose was three-quarters of the minimum fatal dose. The proportion was one-half in specimen III. The paralyzing dose in specimen IV was found to be as low as one-thirteenth of the lethal dose. Specimen V presented this peculiarity: No dose less than the mortal dose had any paralyzing action. Thus it is seen that in different specimens of diphtheria toxin the relation of the paralyzing to the fatal component is not a constant one. In the five specimens investigated the ratio varied from one-thirteenth to unity. The authors conclude that the paralyzing poison is separate and distinct from the acute-acting toxin which is responsible for the fatal outcome in experimental diphtheria. The above researches would seem to favor the hypothesis advanced by Ehrlich; namely, that the remote paralyzing effect of the diphtheria bacillus is to be attributed to a so-called "toxone" as distinguished from the primary intoxication caused by the toxin. Römer and Viereck suggest that just as the toxin stimulates the body to produce an antitoxin, so, also, the toxone causes the formation of an antitoxone. An "antiparalyzin" would neutralize the action of the " paralyzin." An analogy is furnished by solutions of tetanus toxin which contain two poisons: a tetanospasmin which is responsible for the convulsive properties of the tetanus bacillus, and a tetanolysin which is responsible for its hemolytic effect. Both toxins evoke corresponding and distinct antitoxins. Similarly Kruse has shown that in the dysentery bacillus there are a thermostable substance poisonous to guinea-pigs and a thermolabile substance poisonous to rabbits, to each of which toxins there corresponds a separate antitoxin.

That it is possible to neutralize the paralyzing component of the diphtheria bacillus was shown by the fact that in experiments on guinea-pigs one antitoxic unit of the curative diphtheritic serum

abolished the paralyzing effect of the corresponding dose of diphtheria toxin. It has, moreover, been shown by Ehrlich that the toxone has a degree of avidity for antitoxin less than that of the toxin, so that by means of suitable mixtures of diphtheria poison and antitoxin it would be possible to a certain extent to isolate the toxone. Römer has not been able to confirm the results announced by von Calcar several years ago, namely, that it is possible, by means of dialysis, to separate the toxone from the toxin. In view of the experimental evidence which indicates that the symptoms of acute diphtheritic intoxication and those of diphtheritic paralysis are the result of separate components of the diphtheria bacillus, it is difficult to explain how both of these elements can be neutralized by the same curative serum.

The practical applications of the work of Römer and Viereck, so far as these concern the timely and effective administration of diphtheria antitoxin, are of unquestionable importance. The results that bear upon the dual character of the diphtheria poison provide a promising outlook for future research.

## ABDERHALDEN'S TEST FOR MALIGNANT TUMORS.

It seems strange that more work is not being done in this country which would lead to definite conclusions as to the value of this test. American observers have carried on extensive investigations in the serodiagnosis of pregnancy, but the field of cancer diagnosis, one of vastly greater importance, has been comparatively neglected. In other countries, on the contrary, series of tests are constantly being reported, and while the reaction seems to be accurate in nearly all instances, there are occasional failures. These are of such a nature as to justify the belief that some modifications in technique may be elaborated after further experimentation by which these occasional sources of error will be eliminated.

Brockman (*Lancet*, November 15, 1913), from his experiments (twenty-five carcinomatous cases, all positive; twenty noncarcinomatous, all negative reactions) and consideration of the literature, believes that there has already been collected sufficient evidence to show that the serum of cancerous patients contains a specific substance not found in the blood of those not affected, and that it has proteolytic action limited to cancerous tissue. He also finds that stale serum becomes inactive, but regains its action upon the addition of a small amount of fresh human serum; and that the better the patient's general state of health the more rapid and intense is the reaction. This latter statement is of especial interest because of its showing the possibility of very early diagnosis in cases of suspected malignancy—diagnosis at the time when surgery offers the greatest hope of the complete eradication of a cancerous focus. This point was shown very forcibly by one of the cases reported by Wolter (*Russki Vrach*, 1913, No. 32, abstracted in *Zentralblatt f. Chir.* No. 50), where the patient gave a positive cancer reaction, died from some other affection, and at autopsy there was found a new growth only 1 x 1½ cm. in size in the esophagus. The total number of cases examined by him was thirty-two, of which seventeen were cancer, all giving a positive reaction. Fourteen of the fifteen noncancerous patients gave a normal reaction. Erpicum (Contribution à l'étude du séro-diagnostic du cancer) applied the Abderhalden test in forty-two patients with tumors the histological structure of which was determined after operation. All malignant gave positive, and all benign gave negative reactions. Von Gambaroff (*Münchener medizinische Wochenschrift*, 1913, No. 30) reports that in fifty cases of malignant tumors the reaction was positive in forty-nine, the single error in diagnosis appearing in a case of lues. He also found that the serum of those having carcinoma reacts only with carcinomatous material; the serum of those afflicted with sarcoma never with carcinomatous but always with sarcomatous material. He thus confirms Brockman's observations regarding the selective action of the serum.

While most of the reports resemble these, and would seem to show that the present difficulty of early diagnosis of malignancy will almost surely be finally overcome, some dissenting voices are still raised and there are occasionally cases in which positive reaction is not obtained because of some disturbing factor, such as occurred in von Gambaroff's case of lues. Considerable work thus remains to be done toward perfecting the technique. Where could one find a better field for the elucidation of this problem than that offered by the hospitals and research laboratories of New York? With the great wealth of material that passes through our clinics daily conclusions could soon be based upon the results in a thousand rather than in a few scores of cases. It is true that most of the hospitals are not equipped for doing research work in a large way, nor have they the financial resources necessary to obtain skilled workers along these lines; but there are certainly some that have the necessary facilities. Why should American surgeons be obliged to wait until enough evidence has been collected in France, Germany, Belgium, and Russia to decide the value of a test that is of vital interest to tens of thousands of American citizens? Some work along this line has been done here, but far more is necessary, and it should be undertaken systematically and on a large scale.

## The Surgeon-General of the Navy.

The term of Dr. Charles F. Stokes as Surgeon-General of the U. S. Navy expires this month and as usual there is more or less speculation as to who will be his successor. While there is no lack of excellent material in the medical corps of the Navy for this responsible post, we believe no one is better fitted to succeed the surgeon-general than Dr. Stokes himself. He was appointed assistant surgeon in the Navy in 1889, and in his twenty-five years of service has made an enviable record of efficiency and practical accomplishment. His work as commanding officer of a hospital ship, exposed to the fire of criticism from non-medical officers who thought it preposterous that a mere doctor should be in command of a ship, showed him

to be gifted with executive ability and tact far above the ordinary. His four years of service as chief of the Bureau of Medicine and Surgery have added to his other eminent qualifications that of experience. The latest report of the surgeon-general of the Navy, noticed recently in these columns, bears witness to his ability in directing the activities of the medical corps, and it would be a pity were he not retained in his present position, so as to have the time to bring to maturity his plans for the betterment of the service and the elevation of the standard of health of the sailors. We earnestly hope that President Wilson will see fit to reappoint Surgeon-General Stokes to succeed himself as head of the medical corps of the Navy.

### The Problem of the Tubercle Bacillus.

If it be true, as announced in a cablegram to the New York *Times*, that Director Roux of the Pasteur Institute has reported to the Academy of Sciences in Paris that P. Marino, one of the Institute staff, has proved that the tubercle bacillus kills off all other bacteria that enter its chosen terrain, the discovery gives an added interest to the contention of Dr. Stephen J. Maher in his paper in the Medical Record of December 27, to the effect that "mixed infection in tuberculous areas is caused, not by the invading of these areas by bacteria from the outside, but by the development in these areas of the bacterial progeny of the struggling tubercle bacillus." This deduction that Dr. Maher makes from his studies of old cultures of tubercle bacilli is so revolutionary that the temptation has been strong to suggest a possibility of contamination of some of these old cultures; but if, as the cables make Roux report, all old live cultures of tubercle bacilli evolve a toxin that is fatal to other bacteria, the suggestion of contamination falls flat. Again, if Dr. Maher is right, his non-acid-fast coccal and bacillary forms of bacterial life, derived from tubercle bacilli aging in an environment not quite suitable for their further development as tubercle bacilli, thrive in tuberculous areas. This work therefore opens a door for special vaccines and sera in tuberculosis, the very door that the Paris report shuts with such a slam when it says that "because of this toxin both vaccines and sera intended for the cure of tuberculosis are without effect."

### Fatality Following Vagus Resection.

Under the heading "Instructive Mistakes" in the *British Journal of Surgery* for October, 1913, appears an article entitled "Tumor of the Left Vagus Removed in Mistake for a Fibroma, with Fatal Result." A girl, five years of age, had enlarged glands at the left angle of the jaw for one year. For the last two months the swelling had been increasing, the child was not well, and it was noticed that when asleep respiration was difficult. The swelling was firm, extended forward into the carotid triangle, and the separate glands could not be differentiated. At operation some enlarged lymphatic glands were removed, and these were found to rest upon the surface of a large, somewhat lobulated tumor, extending upward to the base of the skull, and deeply to the wall of the pharynx. "Freeing of the deep connections proving difficult, the tumor, which was assumed to be a fibroma springing from the base of the skull, was bisected, the lower half, which was already cleared, was removed, and the upper half was snipped away from the skull with scissors. The whole tumor was 3½ inches in vertical length, and 2 inches in width." No immediate difficulty was experienced either as to pulse or respiration. The next morning the child was apathetic, seemed disinclined to speak, the voice was changed and deeper in tone; pulse, 160, small; respirations, 28. During the next two days she remained apathetic, was drowsy, and it was hard to get her to take nourishment. Moist sounds were heard throughout both lungs, and on the fifth day the base of the left lung was airless. The pulse at this time was 130 and frequently intermittent; respirations, 40; temperature, 102°. The child gradually failed and died on the thirteenth day after operation. Autopsy showed general septic bronchopneumonia in both lungs. The vagus was found to have been divided, a part of the tumor remaining attached to the lower portion. The author states that "No immediate symptoms accompanied the division of the vagus, but it seems clear that it was responsible for the symptoms which developed subsequently and led to the death of the child." This case report emphasizes the validity of the conclusions in the editorial résumé of the subject in these columns last week.

## News of the Week.

**City Vital Statistics.**—For the week ending December 27, the death rate for New York City was 13.18 per thousand of population, the total number of deaths being 1,357. For the corresponding week of 1912, the rate was 14.15 and the total number of deaths 1,403. The death rate for the year 1913 to that date was 13.75, a decrease of 0.33 of a point as compared with last year. The year will show the lowest death rate on record and is the fourth successive year in which the rate has been reduced. The greatest saving of life occurred among children under one year of age, the deaths in this age group numbering 1,669 less than those in 1912. The total number of deaths for the year was 1,917 less than for the previous year. The number of births was slightly decreased, from 135,653 in 1912 to 135,134 in 1913, and the number of marriages also decreased, from 51,703 to 51,267.

**Street Accidents.**—Three hundred and two persons, of whom 149 were children, were killed by automobiles in New York City during the year 1913, according to a report of the National Highways Protective Association. During 1912, the number killed was 221, of whom 103 were children. The street cars caused 108 deaths in the city during the year, as compared with 134 in 1912; and 132 persons were killed by wagons, as compared with 177 in the previous year. In the State of New York outside of New York City, 150 persons were killed by automobiles on the highways, 79 by trolley cars, and 32 by wagons, while for 1912 the figures were 127 killed by automobiles, 79 by trolleys, and 28 by wagons.

**Radium and Cancer.**—Following the optimistic reports made recently of the beneficent effects of radium upon human cancers and the consequent increased demand for the substance, Secretary Lane of the Department of the Interior has suggested to Congress the passage of a law which will give the United States Government control of all radium-bearing ores found in public lands. If this were done promptly it would be possible to withdraw a considerable area of public land

believed to contain radium; unless action is prompt, however, the Secretary fears that these lands will become the basis for private speculation. The proposal called forth a storm of protest from Colorado, whose most promising future resource is said to be the development of lands containing ore from which a large supply of radium may be produced. The Secretary says that chemists of the Bureau of Mines have recently invented a process of extracting radium which promises to be successful, and that "under the endowment of two Americans a building is now being erected in Denver, which with its equipment will be opened for work in February, where an effort will be made to prove the commercial possibility of this American process. If successful this process will be given to the world, and all of the radium secured over and above a small minimum will be the property of the United States and will be put into the hands of the United States Hospital Service for public use."

**Animal Experimentation.**—The following resolutions were adopted by the Federation of American Societies for Experimental Biology at the meeting in Philadelphia, December 31, 1913: (1) We the members of the Federation of American Societies for Experimental Biology—comprising the American Physiological Society, the American Society of Biological Chemists, the American Society for Pharmacology and Experimental Therapeutics, and the American Society for Experimental Pathology—in convention assembled, hereby express our accord with the declaration of the recent International Medical Congress and other authoritative medical organizations, in favor of the scientific method designated properly animal experimentation but sometimes vivisection. (2) We point to the remarkable and innumerable achievements by means of animal experimentation in the past in advancing the knowledge of biological laws and devising methods of procedure for the cure of disease and for the prevention of suffering in human beings and lower animals. We emphasize the necessity of animal experimentation in continuing similar beneficent work in the future. (3) We are firmly opposed to cruelty to animals. We heartily support all humane efforts to prevent the wanton infliction of pain. The vast majority of experiments on animals need not be and, in fact, are not accompanied by any pain whatsoever. Under the regulations already in force, which reduce discomfort to the least possible amount and which require the decision of doubtful cases by the responsible laboratory director, the performance of those rare experiments which involve pain is, we believe, justifiable. (4) We regret the widespread lack of information regarding the aims, the achievements, and the procedures of animal experimentation. We deplore the persistent misrepresentation of these aims, achievements, and procedures by those who are opposed to this scientific method. We protest against the frequent denunciations of self-sacrificing, high-minded men of science who are devoting their lives to the welfare of mankind in efforts to solve the complicated problems of living beings and their diseases.

**Civil Service Medical Board.**—The Illinois State Civil Service Commission recently named a permanent medical board which will have charge of its medical examinations in the future. The board is composed as follows: *Chairman*, Dr. James B. Herrick, Chicago; *Surgery*, Dr. Charles H. Culhane, Rockford, and Dr. Dean H. Lewis, Chicago; *Medicine*, Dr. George F. Suker and Dr. W. D. Napheys, Chicago; *Pathology*, Dr. Ludwig Hektoen, Chicago; *Nervous and Mental Diseases*, Dr. James C. Gill and Dr. L. Harrison Mettler, Chicago, and Dr. Harold D. Singer, Kankakee.

**Life Extension Institute.**—With ex-President Taft as chairman of its board of directors and Colonel Gorgas as consultant in sanitation and hygiene, a "Life Extension Institute" was incorporated in New York on December 29, 1913. The purpose of the corporation is the lengthening of human life by the application of modern science, and it will perform this service for life insurance companies and for the general public by examining periodically the physical condition of policyholders and other individuals and by disseminating life-saving knowledge. The institute has a "Hygienic Reference Board," which will help to determine the truth of hygienic questions referred to it, and will employ experts throughout the land to act as medical examiners and to cooperate in this new movement to prevent and to check disease. Its central office will be at 25 West Forty-fifth street, New York, but it plans to make arrangements with life insurance companies, schools, industrial establishments, clubs, etc., and to work with hygienic agencies and movements of all kinds throughout the country, including those connected with the tuberculosis movement, the social hygiene movement, the eugenics movement, and the public health departments, federal, State, and municipal. The originators believe that the results of this work may in time favorably influence the general death-rate of the country. The method which it will use to prolong life is the same as that applied to ordinary machinery—inspection and repair.

**The Herter Lectures** of the University and Bellevue Hospital Medical College will be given during the week beginning January 12, 1914, at Carnegie Laboratory, 338 E. 26th street, New York City. Professor Sven Hedin will lecture on "Colloids and Their Relation to Biological Chemistry."

**Public Health Lectures.**—The Committee on Public Health Education of the New York County Medical Society announces the fourth annual series of lectures will be given at the Academy of Medicine, New York, at half-past three on the afternoons of January 8 and 22, February 5 and 19, and March 5; and also at quarter past eight on the evenings of January 13 and 27, and February 10 and 24. The lectures will cover the following Topics: Athletics; The Backward Child; Everyday Troubles of the Eye, Ear, and Nose; Drug Addictions; Government Protection Against Disease; Sanitation for Workers; Prevention of Nervous Diseases. The officers of the committee are Dr. Phœbe M. Van Voast, Chairman, and Dr. Esther Leslie Jefferis, Secretary.

**Kansas Public Health Commission.**—Governor Hodges of Kansas has recently appointed a special Public Health Commission for that State, similar to the one appointed last January by Governor Sulzer of New York. The Kansas Commission is composed of seven members who are to collect facts, receive suggestions, and make recommendations as to changes in the public health laws and their administration in the State. The New York Commission has been requested to send to

Kansas copies of its findings, conclusions, and recommendations.

**Personals.**—Dr. Everett E. Potter of North Pownal, Vt., has been appointed by Governor Fletcher of that State to serve as State Senator for the unexpired term of Senator Mattison, deceased.

Dr. Hermann M. Biggs, who recently retired from the position of general medical officer of the New York City Board of Health, will, it is announced, be appointed by Governor Glynn, State Commissioner of Health.

Dr. B. F. Hawk of Harper, Kan., has been appointed superintendent of the new Kansas State Hospital for the Insane at Larned.

**Charitable Gifts.**—St. Luke's Hospital, New York, receives a bequest of $7,500 of the late Mr. Henry M. Sands of this city.

By the will of the late Judith L. Frechie of Philadelphia bequests are made as follows: Jewish Maternity Hospital $500, Jewish Hospital Association $1,000, Mt. Sinai Hospital $500.

**The Late Dr. Phelps.**—The following resolutions have been adopted by Dr. Phelps' colleagues at St. Vincent's and Bellevue Hospitals:

The Medical Board of St. Vincent's Hospital records with profound sorrow the death of Dr. Charles Phelps, who for forty-three years had been Visiting and Consulting Surgeon to this institution. His great skill and kindly sympathy were always at the service of the sick and suffering poor, and his vast experience and wise counsel always available to his colleagues.

JOSE M. FERRER, *President.*
CHARLES E. NAMMACK, *Secretary.*

The Medical Board of Bellevue Hospital announces with deep regret the death of Dr. Charles Phelps, who, entering Bellevue Hospital as a member of the interne staff in 1859, was one of its oldest graduates, and who for thirty-five years since then has been a Visiting or Consulting Surgeon to that institution. During all this time Dr. Phelps has never spared himself in the service of the hospital, giving abundantly of his time and skill to the suffering. In the councils of his colleagues his advice, enriched by long experience, was frequently sought and freely given.

GEORGE DAVID STEWART,
*President of the Medical Board.*
CYRUS J. STRONG,
*Secretary.*

**Obituary Notes.**—Dr. EMMA E. MUSSON of Philadelphia, a graduate of the Woman's Medical College of Pennsylvania, Philadelphia, in 1883, professor of otology in the Woman's Medical College, a former worker with Dr. Grenfell in the Labrador mission, and a member of the American Medical Association, the Medical Society of the State of Pennsylvania, and the Philadelphia County Medical Society, died at her home from pneumonia, after a short illness, on December 28, aged 52 years.

Dr. FRANCIS L. PARKER of Charleston, S. C., a graduate of the Medical College of the State of South Carolina, Charleston, in 1858, a surgeon in the Confederate Army during the Civil War, formerly dean of the Medical College of the State of South Carolina, and at the time of his death emeritus professor of anatomy in the same institution, and a member of the South Carolina and Charleston County Medical Societies, died at his home on December 5, aged 77 years.

Dr. D. H. KEY of Monroe, La., a graduate of the New Orleans School of Medicine in 1860, died at St. Francis' Sanatorium, Monroe, on December 7, after a long illness.

Dr. JAMES S. MORTON of Hartford, Ky., a graduate of the University of Louisville, Medical Department, in 1850, died at his home on December 4, aged 85 years.

Dr. NOEL M. DARDEN of Norwood, Ga., a graduate of the Medical College of Georgia, Augusta, in 1879, died on December 4.

Dr. JACOB W. E. K. DAVIS of Omaha, Neb., a graduate of the University of Buffalo, Medical Department, New York, in 1887, died suddenly on December 5, aged 64 years.

Dr. EDGAR MARTINDALE HERMANCE of Yonkers, N. Y., a graduate of the College of Physicians and Surgeons, New York, in 1878, formerly Commissioner of Public Safety of Yonkers, a member of the Board of Education, and president of the Health Board, attending physician to St. Joseph's Hospital, and a member of the New York State and Westchester County Medical Societies, and the New York Academy of Medicine, died at his home, from pneumonia, on December 22, aged 59 years.

Dr. FRANCIS H. O'CONNOR of Brattleboro, Vt., a graduate of the Long Island College Hospital, Brooklyn, in 1898, and a member of the Vermont State and Windham County Medical Societies, and widely known twenty years ago as a pitcher on the baseball team of the University of Vermont, died at his home from heart disease on December 26, aged 45 years.

Dr. FRANK EDWARD AGNEW of Paterson, N. J., a graduate of the College of Physicians and Surgeons, New York, in 1885, a member of the Medical Society of New Jersey and the Passaic County Medical Society, physician in charge of the Paterson Isolation Hospital, and formerly city physician of Paterson, died at his home from pneumonia on December 16, aged 49 years.

Dr. WILLIAM C. BARTRAM of Newburgh, N. Y., a graduate of the College of Physicians and Surgeons, New York in 1904, a member of the American Medical Association, the New York State and Orange County Medical Societies, and the Newburgh Medical Society, and assistant surgeon to St. Luke's Hospital, Newburgh, died at his home from blood poisoning resulting from the pricking of his finger during an operation, on December 17, aged 34 years.

Dr. E. L. B. GODFREY, formerly of Camden, N. J., died at South Pasadena, Cal., on December 18 at the age of 63 years. He was graduated from Jefferson Medical College in the class of 1875. He was a member of the Camden County Medical Society, a member and former president of the New Jersey State Medical Society, a Fellow of the American Medical Association, president of the New Jersey State Sanitary Association, and of the New Jersey State Board of Medical Examiners.

Dr. JOSEPH P. JOHNSON died at Hightstown, N. J., on December 18 at the age of 76 years. He was graduated from the Homeopathic Medical College of Philadelphia in the class of 1867. He was a veteran of the Civil War, a member of the Common Council for three years, president of the first Board of Trade of Hightstown, a member of the local Board of Education, and also a member of the United States Board of Pension Examiners.

Dr. GARY H. WOOD of Antwerp, N. Y., a graduate of the Long Island College Hospital, Brook-

lyn, in 1877, a member of the New York State and Jefferson County Medical Societies, and for five years a member of the New York State Legislature, died at his home from Bright's disease on December 18, aged 59 years.

Dr. RICHARD G. P. DIEFFENBACH of Newark, N. J., a graduate of the College of Physicians and Surgeons, New York, in 1874, a member of the Medical Society of New Jersey and the Essex County Medical Society, visiting physician to the Newark German Hospital, and treasurer of the same institution, died at his home from apoplexy on December 17, aged 61 years.

Dr. JAMES WILLIAM KORNEGAY of Mount Olive, N. C., a graduate of the College of Physicians and Surgeons, Baltimore, in 1894, died at his home from paralysis on December 12, aged 47 years.

Dr. JOHN CAVEN of Toronto, Canada, a graduate of the Toronto School of Medicine in 1886, and a Licentiate of the Royal College of Physicians, London, 1886, formerly professor of pathology in the University of Toronto, died at his home from Bright's disease on December 10, aged 52 years.

Dr. BENJAMIN FRANKLIN WAGENSELLER died at Selinsgrove, Pa., on December 20, at the age of 75 years. He was graduated from Pennsylvania Medical College in the class of 1861. In the following year he was commissioned assistant surgeon to the 139th Regiment, P. V. I., and in 1864 he was promoted to a surgeoncy in the 158th Regiment with the rank of major. He was a former president of the Northumberland and Snyder County Medical Societies, a member of the Medical Society of the State of Pennsylvania, a Fellow of the American Medical Association, surgeon to the Pennsylvania Railroad and Statistician to the County Board of Health.

Dr. GEORGE W. ZIEGLER died at Philadelphia on December 24 at the age of 52 years. He was graduated from Jefferson Medical College in the class of 1887.

Dr. W. H. STEARNS of Los Angeles, Cal., a graduate of the University of Southern California, College of Medicine, Los Angeles, in 1899, died at his home from pneumonia, after a short illness, on December 16, aged 44 years.

## Obituary.

### SILAS WEIR MITCHELL, M.D., LL.D.,

PHILADELPHIA.

AMERICAN medicine and American letters have suffered a great loss in the death of Weir Mitchell which occurred in Philadelphia early Sunday morning. Dr. Mitchell came of a medical family, his grandfather, Alexander Mitchell, having been one of the leading physicians of his time in Virginia, and his father, John Kearsley Mitchell, a well-known practitioner in Philadelphia and one of the faculty of Jefferson Medical College. Weir Mitchell was born in Philadelphia on February 15, 1829. He was a student at the University of Pennsylvania but was forced to give up his studies there before graduation on account of illness. Upon recovering his health he did not return to the University but entered Jefferson Medical College from which he was graduated in 1850. He began the practice of his profession in Philadelphia, but had a strong inclination toward literature and yielded to it so far as to write a small book of verse. This he showed to Oliver Wendell Holmes who gave him the advice to hide the book until he was forty years old and then see what he thought of it, and also told him he should practise medicine or write books but not try to do both. Mitchell had the sense to accept this sage counsel and chose medicine. Even when, later, he began to write novels he did it only during his vacations and never allowed himself to steal the time that belonged to medicine.

During the Civil War Dr. Mitchell served in the medical corps of the army and while in charge of one of the military hospitals made a special study of wounds of the nervous system and of traumatic nervous disorders, his work on "Gunshot Wounds and Other Injuries of the Nerves" being founded on his observation of the wounded soldiers. Prior to this he had published a work entitled "Researches Upon the Venom of the Rattlesnake" based upon several years' study of the chemistry and physiological action of snake venoms.

To the laity and the medical profession abroad Dr. Mitchell was perhaps best known as the originator of the treatment of neurasthenia by rest and feeding—the "Weir-Mitchell Treatment"; but to Americans he was known not only as a skilful neurologist, but as a biologist and naturalist, a poet and novelist, a man of brilliant parts and a whole souled and kindly gentleman.

### CHARLES PHELPS, M.D.,

NEW YORK.

Dr. CHARLES PHELPS of New York, for forty years a member of the staff of Bellevue Hospital, died at his home in this city on December 30, in the eightieth year of his age. Dr. Phelps was born in Milford, Mass., in 1834, and was graduated from Brown University in 1855 and from the College of Physicians and Surgeons, New York, in 1858. He served as a surgeon during the Civil War and at its close began the practice of medicine in New York, where he remained until his retirement in 1909. He was for many years an attending surgeon to St. Vincent's Hospital, and consulting surgeon to Gouverneur Hospital, and was at one time president of the Board of Police Surgeons of New York. He was also a member of the American Medical Association, the New York State and County Medical Societies, the Bellevue Hospital Alumni Association, and the New York Academy of Medicine, and was the author of a textbook on "Injuries to the Brain," and various monographs on the surgical subjects.

### FREDERICK CARL BUSCH, M.D.,

BUFFALO, N. Y.

Dr. FREDERICK CARL BUSCH, professor of physiology in the Medical Department of the University of Buffalo, N. Y., since 1900, and assistant in the State Institute for the Study of Malignant Disease, died at the hospital of the Institute on January 3, aged 40 years. Dr. Busch was graduated from Cornell University in 1895 and from the Medical Department of the University of Buffalo two years later. He was a member of the American Medical Association, the American Association for Cancer Research, the Medical Society of the State of New York, and the Erie County Medical Society, and a fellow of the American Association for the Advancement of Science. He had done much experimental work on the problems of cancer and on various phases of physiology. His death was due to cancer from which he had suffered for several years.

### OUR LONDON LETTER

(From Our Regular Correspondent.)

SIGHT TESTING FOR SEAMEN, RAILWAY DRIVERS, ETC.—LONDON AMBULANCES—RESEARCH—HOSPITAL DISPUTE—MEDICAL WOMEN FOR INDIA—PAYING HOSPITAL—KING EDWARD'S HOSPITAL FUND—OBITUARY.

LONDON, December 19, 1913.

ALL through the month we have been talking about the sight tests in use. The discussion seems to have arisen in consequence of the Board of Trade having made some alterations in the tests to which it requires officers in the mercantile marine to be subjected. Some of these officers seem to have feared that a too severe or faulty test might interfere with their employment—a natural enough fear perhaps; but what is more surprising is to find that certain vested interests have made an outcry against increased efficiency as likely to interfere with business, and declared the Board of Trade has acted on account of the pressure of scientific opinion rather than in obedience to the needs of practical life at sea, and on the railways. This contention has brought the public, as well as the profession, into the discussion, for no one would care to find himself on board a ship under the command of a color-blind captain or in a train driven by a man with such defective vision. The position is that we have different tests for the navy and for merchant ships, and, again, for railway companies. Cases occur of one authority accepting men who are rejected by another. An officer who had passed the Board of Trade was only saved from causing the loss of his ship by the appearance on deck of another officer just in time to prevent collision. On reaching home he had himself examined again by the Board, and again passed. Dr. Edridge-Green, the leading medical authority on the subject, points out that the fact which makes color-blind men most dangerous is that though they may name lights correctly under ordinary conditions they will under unusual conditions confuse red and green or perhaps feel sure that one is the other. The error can be demonstrated by his lantern, which is used by the Admiralty but will not be detected by the Board of Trade tests, and yet this Board often rejects men whom Dr. Eldridge-Green afterwards finds competent. He regards an inquiry as urgently needed in order to establish a standard both for color and form, based on a series of careful experiments. This seems a most reasonable proposal, and the inquiry should be conducted by experts, all kinds of lights at different distances, under various conditions being used.

The late Mr. Nettleship, whose book on "Accidents from Defective Light" you are no doubt familiar with, collected the cases of disaster due to such defects, and also a large number in which there had been a narrow escape. Both these lists could now be greatly lengthened, but practically nothing has been done. Nettleship urged that persons concerned in accidents ought always to be carefully examined, but one scarcely ever hears of this being done. Simple as it is, witnesses and others might well be tested with a view of weighing the value of their evidence. For conflicting statements—obviously made in good faith—are often heard at investigations as to the cause of accidents.

The railway companies generally leave the testing of candidates to their medical officers, to whose department it naturally belongs.

The Liverpool Pilotage Authority, which controls the testing for the Mersey, makes hundreds of examinations every year, and its regulations are somewhat less severe than those of the revised Board of Trade, but are considered efficient. The Holmgren wool test has been discarded. The lantern test is conducted in a room shaded by heavy curtains, the coloured lights being exhibited at about 6 feet away from the candidate. The lights are about ¼ inch in diameter, but can be reduced to a pin-point as the Board of Trade uses. But this is not often done, and a further difference is that at the Board's test the candidate stands behind the lantern and looks over it at the pin-points in a mirror some 15 feet in front of it, having previously been in a dark room for a time. Another test for color at Liverpool is looking through a series of tinted glasses held up to the light. For form the Snellen card test is employed—the candidate being required to read three of the five letters on the last line but two at a distance of 16 feet. The last two, though required by the Board of Trade, are regarded as unnecessary. If a candidate does not quite satisfy the examiner he is taken on the Mersey at night and put through a full trial as to the vessels passing up and down the river.

The ambulance service for illness and infection is effectively carried on by the Asylums Board with some 60 horse and 30 motor vehicles. Four years ago a Home Office committee recommended that the Board should further enlarge its work by providing for an accident service. At once the jealousy of the County Council was roused, and although it had no experience whatever on the subject, by dint of political efforts it secured an Act of Parliament authorizing it to undertake this service. Nothing has so far been done, unless complicating matters by displays of the difficulty of co-operation be so considered. Most boards or committees are ready to extend the sphere of their operations, and when more than one will be affected by a proposed change different policies are sure to be put forward. It is so in this case. There are in working order a number of ambulances under several public bodies, and the Asylums Board, with its large staff, eight or nine stations and some 100 vehicles, could easily take the control of the whole. But the County Council's desire to dominate every service it can grasp has stood in the way these three or four years. At length the public intimated that something ought to be done, and that co-operation should be easy. Thereupon the Council asked the Asylums Board to prepare a scheme which that body with its experience quickly did, only to see it rejected without any reasonable discussion, and a resolution passed for the Council to prepare a scheme of its own, as it would have to bear the cost and would not submit to the control of the Board which had the experience. The truth is these opposing opinions and jealousies are those of the officials, and the members of the two bodies ought to set them aside, exercise their proper control over their servants and compel them to pull together. As to the cost, whatever is incurred will come from the pockets of the rate payers.

At the meeting of the Council this week there was a good deal of lively talk which on the whole perhaps indicated discontent of the majority at the way time had been frittered away, and perhaps a

consciousness among some of the unworthiness of their jealousies. At any rate, the chairman of the committee which inquired into the matter, advocated co-operation, and said at a conference they found the Board emphatic in the expectation of holding the control. This really seemed the one point at issue which caused difficulty, for all the others were mere details easily altered. Yet, while saying the need of London was a crying one, he held with the majority that co-operation should be supplementary to a new service of their own. If anything could disturb the apathy of London rate-payers we might expect them to wake up and insist on the Council abandoning its domineering attitude, and handing over the service to the Board that has experience in the matter and would carry it out at far less cost.

The trustees of the Beit Memorial for Medical Research have elected to Fellowship 11 out of 35 candidates at the fifth election.

Mount Vernon Hospital began legal proceedings against the British Medical Association on account of a "warning notice" issued in the *Journal* respecting the dispute concerning the medical staff. The judge has adjourned the action expressing the hope that on the first day next session the parties may be able to announce a satisfactory ending of the whole business.

The Association of Registered Medical Women protests against a scheme of service proposed for India on the ground that no first class medical woman will work under a lay committee which has power of punishment for acts which that committee may disapprove.

A paying hospital was opened on Monday for patients of moderate means who do not wish to receive charity but cannot afford some of the expensive nursing institutions. They will be attended in the new hospital by their own medical men, and a separate room for every one will be provided.

King Edward's Hospital Fund will benefit by about £465,000 from the will of the late Sir Julius Wernher.

Mr. Sydney Jones, consulting surgeon to St. Thomas' Hospital, has died after a distinguished and long career, at the age of 82. He was elected on the staff of the hospital in 1860, and served in several departments, and taught in the school. In 1871 he became full surgeon and lecturer on surgery, and in 1891 consultant. At the Royal College of Surgeons he had been a councillor, and at the Sister College surgical examiner. The later office he afterwards also filled for the University of Glasgow. He was consulting surgeon to several dispensaries and medical charities. He contributed to St. Thomas's Hospital Reports and the museum catalogue.

Dr. J. C. Grey of Telford met his death on the 10th from strychnine taken in mistake. He instantly telegraphed to his medical neighbors the fact, and they attended at once, but on arriving by motor found he was dead. He was 63 years of age, and had practised at Telford most of his professional life.

## OUR LETTER FROM THE PHILIPPINES.

(From Our Regular Correspondent.)

A PLAGUE CASE—OPPOSITION OF NATIVE PHYSICIANS TO THE CAMPAIGN AGAINST CHOLERA—GARBAGE COLLECTION — LEGISLATION AGAINST PUBLIC HEALTH.

MANILA, P. I., November 29, 1913.

AFTER an absence of two months, another death from plague occurred in a house located in a lumber yard at No. 745 Interior, Calle Echague. This address is in the same general neighborhood in which plague appeared over a year ago. Extensive rat catching has been done in this section during the past few months but no plague rats were found. Considerable difficulty has been experienced in eradicating rats from lumber yards, owing to the impracticability of moving the heavy timbers about on account of their size and number. The spaces between and under the different dimensions of the timber afford excellent harboring places for rats. The last case of human plague occurred in Manila on September 20 and the last case of rat plague occurred on September 6.

Much opposition has been encountered by the Bureau of Health in its campaign against cholera from the physicians of Manila on account of an order which required an autopsy in practically all cases of death. The order was issued for the purpose of detecting cases of cholera in the dead bodies of persons in which death was ascribed either purposely or accidentally to some other cause and on that account the premises in which they died escaped the usual disinfecting and other anticholera measures. That the order of the Bureau of Health was fully justified was shown by the fact that in the space of a week in twelve of the cases that were autopsied the deaths which had been reported as due to other causes were found actually to have been due to cholera. It is also of interest to observe that in two bodies in which death was obviously due to strangulated hernia and purulent peritonitis that Koch's vibrios were isolated from the intestines. On the other hand, the private practitioners claim that it is a reflection on them and injures them in the eyes of their patients whenever bodies are sent to the morgue for autopsy in which they have already reported the death as due to other causes. The Bureau of Health has now issued additional instructions that rectal specimens shall be taken from the bodies of all dead in Manila in order that an examination for cholera vibrios may be made. All houses in which deaths occur, regardless as to the reported cause, are disinfected in so far as toilets, linen, receptacles, and other articles with which the deceased might have come in contact are concerned.

The private company which was organized in Manila some time ago and to which was awarded the contract for collecting the city garbage has encountered many difficulties in complying with its contract. Up to the present the company has failed to dispose of the city garbage and refuse in a sanitary manner and the Municipal Board threatens to cancel its contract. The plant which the company erected for the reduction of the garbage and for destroying the refuse is entirely inadequate in capacity to meet the demands of the situation and in order to dispose of all the material which arrives at the plant daily the company has begun to dump garbage and refuse on the beach. This has been responsible for the breeding of flies which up to the present time has reached proportions which far exceed anything that has been seen in Manila in many years. A veritable plague of flies on the garbage dump has resulted and these are gradually extending to the city and on account of the presence of cholera are regarded as a very serious menace to the health of the community.

A garbage ordinance which provides for placing garbage and refuse in separate receptacles and which gives the householder an opportunity to rent a sanitary garbage pail from the city of Manila at

a cost of $1.50 per annum has finally been passed by the Municipal Board. This ordinance met with violent opposition from the Filipino press, which thought that it was unnecessary to have a tight and separate receptacle for garbage, and it was only after the strong support given the measure by the new Governor-General that it was finally enacted into law. The object of the ordinance is two-fold: first, to provide a closed, impervious receptacle for garbage so as to avoid smells as much as possible and to make it inaccessible to rats and thereby aid in the anti-plague campaign and, second, to insure householders a garbage can at a reasonable outlay. Up to the present time the Director of Health has had authority to compel householders to provide themselves with garbage cans, but these were so frequently stolen and the hardship on householders became so great that it was deemed impracticable and unfair constantly to require them to buy new receptacles. Under the new plan a garbage can of one type will be used and properly marked and as the city is responsible for replacing the can in the event that it is stolen there will be no object to steal cans because there will be no place at which they can be sold.

Recently the Bureau of Health has published a small "Sanitary Inspector's Handbook" in which the simple procedures for sanitating towns in the provinces were outlined in detail in simple language. These books were sent out with instructions that in the course of a few months an examination would be held in order to determine whether medical officers and sanitary inspectors had acquainted themselves with their contents. This has also produced violent opposition in the Filipino press on the ground that it is beneath the dignity of a doctor to be called upon to pass an examination on a sanitary inspector's handbook, more especially as the diploma which he holds from his medical school is sufficient assurance that he has all the knowledge required on the subjects dealt with. These critics did not state how the diploma of a medical officer would assist him in acquainting himself with the advances and new discoveries in sanitation which have been made since he left the medical school.

There is also before the Legislature a bill which provides for the establishment of a Council of Hygiene which is to have power to annul any sanitary ordinance or legislation which in its opinion interferes with the habits or customs of the Filipino people.

*December* 25, 1913.

Some Medical and Social Aspects of Mental Disease Due to Alcohol: Notes of a Conference Held at the Psychopathic Hospital, Boston, Massachusetts, Before the Legislative Commission on Drunkenness, November 24, 1913.

1. Introductory Remarks. W. Channing.
2. Work of Massachusetts Legislative Commission on Drunkenness, 1913. M. J. Murray.
3. Report of Clinical Demonstration of Alcoholic Mental Diseases. H. M. Adler.
4. Consensual Amyosis to Blue Light as Shown in Certain Alcoholic Cases. G. E. Eversole.
5. Alcoholic Amentia. A. W. Stearns.
6. Notes on After-Care and Moral Suasion Work with Alcoholics. A. W. Stearns and M. C. Jarrett.
7. On Institutional Requirements for Acute Alcoholic Mental Disease in the Metropolitan District of Massachusetts. E. E. Southard.

3. **Alcoholic Mental Diseases.**—H. M. Adler states that after excluding simple drunkenness and delirium tremens, both of which are specifically excepted by law from the scope of work of the Psychopathic Hospital of Boston, one has to deal with the following types of alcoholic mental diseases: pathological intoxication; acute alcoholic hallucinosis; Korsakow's psychosis; alcoholic jealousy-psychosis; dipsomania; alcoholic epilepsy; various residual dementias following various forms of alcoholic disease; and forms as yet ill-defined or not yet generally recognized (e.g. the peculiar variant of delirium tremens called Stearns' alcoholic amentia).

7. **Institutional Requirements for Acute Alcoholic Cases.**—E. E. Southard points out that the metropolitan hospital for acute alcoholic cases should have an adequate staff of physicians, investigators, and trained workers in every department, and should maintain a high standard of efficiency, combining the practical equipment of the best general and surgical hospitals. The facilities for isolation of patients preserving their relative freedom, so that noise shall disturb neither other patients nor the public, the facilities for approved methods in hydrotherapeutics, and the quota of specially trained nurses and attendants should be as good as obtainable. Opportunities for the teaching of students and practising physicians concerning the diagnosis and treatment of these diseases should be afforded; and the institution should be so managed as to attract the best grade of physicians and nurses, as well as investigators, to its wards. One of the most prominent functions of such a hospital is the out-patient and after-care service. Every arm of social service should be extended to increase the number of persons now being saved, from recurrence of alcoholism. The out-patient department should adopt every device of mental and social hygiene which can be used to correct and control the drunkenness evil. Voluntary resort of prospective patients should be encouraged, and the work of the churches, and various existing social agencies, should be supplemented so far as possible. Highly trained officers from the institution should be detailed to visit the lockups at stated hours or on special call, to pick out alcoholic or other cases of mental disease from among those arrested for drunkenness.

7. The Etiology of Pellagra. P. Bartholow.
8. The Treatment of Broncho-pneumonia in Children. A. Goltman.

1. **The Cancer Research Hospital.**—J. Ewing states that one may never know just why cancer cells grow lawlessly, but one can elucidate a vast number of conditions under which they are observed to do so, and perhaps remedy the conditions. The influence of racial, local, and personal habits upon the nutrition and functions of different organs; the traces of heredity; the evidence and nature of local tissue and general constitutional predisposition; the influence of chronic infection, of trauma, and many other matters enter into the etiology of tumors, and should be pursued in a cancer hospital by observation, analysis, and experiment, by clinician, chemist, and pathologist. The cancer hospital offers conditions where the natural history of tumors can be observed and recorded in all its phases, and where one's knowledge of this vast and comparatively neglected department of medicine can be greatly amplified. For this purpose, a well organized department of pathology is essential, every type of

patient in any stage should be admitted, and the public should be educated to the necessity of postmortem study of every fatal case. Therapeutic studies are bound to claim a large share in the activities of a cancer research hospital. In fact a hasty tour through such institutions in England and the Continent might suggest that this is their only real interest. It would at least convince the visitor that the partial success of the palliative treatment of inoperable cancer fully justifies all the support these institutions have received. To the harsh critic, the treatment of inoperable cancer is nothing more than a form of euthanasia, and such as a rule it proves to be. Yet the palliative treatment of these patients is a worthy service, demanding far more patience and skill than are involved in most routine functions of the physician. It is an intellectual rather than a mechanical occupation.

2. **Ileocolitis with Meningeal Symptoms.**—A. L. Goodman notes that any form of enteritis may give rise to cerebral symptoms. Genuine cholera infantum, however, does not cause meningitic disturbances, because, as a rule, the patient rapidly becomes comatose, and the nervous system has no time to react in the form of excitement. Convulsions in the course of enterocolitis are sometimes observed, and these cases must be differentiated from those forms of intestinal infection occurring in epileptics. Gastrointestinal autointoxication in children may give rise to conditions very closely approximating the picture of meningitis. The gastric symptoms, the indicanuria, and the prompt effect of intestinal evacuation, permit the differentiation of these cases from meningitis. Lumbar puncture may also assist in the differential diagnosis.

3. **Serodiagnosis of Cancer and Pregnancy.**—C. F. Ball presents a comprehensive review of this subject, and reports some of the interesting results of his own investigations. His further work with the different kinds of tumor tissues appears to make the diagnosis of cancer rather more complicated than suspected, but more interesting, inasmuch as there appears a possibility of being able to designate the kind of tissues involved. He has been led to think of such a possibility when comparing the clear cut differences of reaction in his first series of cases, using the sarcoma protein, with subsequent tests made with the protein prepared from an epithelioma of the cervix. When using this kind of material he was not able to get satisfactory results. Pregnant conditions would, apparently, give the malignancy reaction in cases known not to be malignant, probably because of the ability of the pregnant ferment to digest uterine tissue as well as placental tissue. The author believes this is also an explanation for some of the adverse findings by others in giving their reports, but not specifying the kinds of tissue used. The same result was obtained when using albumin prepared from an epithelioma of the skin of the hand. He used this tissue only a very few times, fearing to continue on account of the possibility of the sweat glands complicating the test. Some of the conflicting reports relative to the value of the test are attributed to the use of different and poorly prepared materials. In conclusion the author emphasizes the following points: (1) The desirability of always working with at least two kinds of tissues, one of these necessarily to be carefully prepared placenta; (2) the necessity of designating the kind of material used in all experimental work when other than placental tissue is used; (3) the advisability of associating this test with experimental tumor transplantations in animals; and, (4) further experimental work directed toward eliminating, if possible, all sources of error in the present technique, or the substitution of a trustworthy modification.

6. **Acromial Breathing in Diagnosis of Apical Tuberculosis.**—N. Magida confirms the value of auscultation at the acromial process in the diagnosis of early lesions of the pulmonary apices. In looking over the histories of fifty-two cases, consisting of twenty-eight in the first stage, fourteen in the second, and ten in the third, he found acromial breathing present in all the first stage cases, in eight of the second, and in two of the third. It would seem that it is a valuable method in first stage cases, and since that stage is the most important from a diagnostic point of view, and as the method is so easily acquired, it should be universally employed. It should also help toward ascertaining the advanced stages of tuberculosis, as the further advanced a case is, the less probability there is of getting evidence from auscultation of the acromion process.

8. Burn of Eyes from Contents of Golf-Ball Core. H. Lowell
9. Quinin and Urea Hydrochlorid in the Treatment of Sciatica. H. A. Cables.

1. **Control of Cancer.**—J. C. Bloodgood points out that the proportion of cures of fully developed cancer is small, but cures have been made and the possibility of increasing their number is by no means out of the question. In the Johns Hopkins Hospital Surgical Clinic 80 per cent. of the cases that could be diagnosed only by exploratory incision or after operation were cured, while in the cases that could be diagnosed as cancer by retraction of the nipple or skin adhesion the proportion of cures after five years was 25 per cent., but both tumors alike were pathologically the same. Waiting for a possible clinical diagnosis means greatly lessening the chance of cure. This is true of all types of cancer in all parts of the body. The author, in studying 820 pathologically developed cancers, found no well-taken history that did not reveal a previous defect that might be accepted as one of these so-called benign growths. He calls these "precancerous" growths, and believes that with their early recognition one can greatly reduce the cancer mortality, especially that from external or mucous membrane cancer. In cancer of the internal organs it is more difficult to demonstrate the precancerous lesion. In cancer of the stomach the patient is fortunate if the appearance of obstruction is early, and his chances are greatly lessened if the early symptoms are slight. In curable cancer good surgery is important, and delay or too restricted operation may be disastrous. In most external cases of precancerous growths the lesion can be cut out under local anesthesia at slight expense and inconvenience. In any apparently benign growth a properly performed operation does not harm, and if malignancy is found existing it may remove a probable focus of future malignant disease. It is the education of the public on these matters that is needed at the present time.

4. **Diphtheria Carriers.**—W. A. Womer presents the results of his experience in the use of staphylococcus spray in the endeavor to lessen the period of isolation of diphtheria patients. The spray consisted of a bouillon culture of *S. aureus* at least twelve hours hours old, or a fresh suspension in salt solution. It was prepared in the municipal laboratory and delivered personally to the

attending physician or nurse with explicit directions as to its use. Only one strain was used; the directions were to spray copiously both nose and throat three or more times a day and not to use any other treatment. The author draws the following conclusions: (1) The use of the spray causes no unpleasant symptoms. (2) The use of the spray does not appreciably lessen the period of quarantine. (3) The preparation and distribution of the spray entail a large amount of work if there are many cases. (4) Apparently most of the carriers do not spread the disease after sixty days from the day the disease begins. (5) Public health officials could work more effectively if they had some practical method of determining the virulence of diphtheria bacilli found in the throats of carriers.

**6. Amnesias of Tobacco and Malarial Origin.**—S. P. Goodhart reports two cases of temporary amnesia, one from the excessive use of tobacco, the other a result of malarial infection. The first patient was a prominent lawyer and teacher, who had indulged in excess in the use of tobacco on account of recent mental and emotional stress. The amnesia appeared suddenly with a dazed condition for a half hour followed by three weeks of nearly complete forgetfulness of past and current events, but apparently without any mental symptoms other than those dependent on the amnesia. Then it gradually began to disappear but the complete rehabilitation was as sudden as the onset, and seemed to take up the normal mental activity at the point where it had been interrupted. Withdrawal of tobacco, rest, and nutritional care were all the treatment used. This was several years ago; since then slighter amnesic attacks have followed the excessive use of tobacco and have been relieved by similar treatment. The second patient was a woman teacher, aged 27, whose mother suffered from epilepsy and who was herself somewhat high-strung and nervous. The attack, in this case, was sudden after intense emotional strain and fatigue and was immediately preceded by severe occipital headache. The amnesia was complete for the events of the previous forty-eight hours but less so for events more remote. Malarial symptoms appeared two days later, and the case was a typical tertian with finding of the plasmodium. The amnesia continued long after the malarial symptoms ceased and there is yet only partial restoration of past recollections.

**1. Gunshot Injuries of the Arteries.**—G. H. Makins points out that there have been changes in the shape of the rifle bullet since 1900. That used in the Balkan wars was longer, narrower, and more pointed than that used in the South African war, and as a result the character of the injuries was different. The chief features in the wounds of vessels produced by bullets of small caliber are lessened liability to external secondary hemorrhage, and the greatly increased frequency of the development of some form of aneurysm. These peculiarities are attributed partly to improved surgical treatment, and partly to the narrow clean track of the bullet. It is a primary rule in surgery that the bleeding vessel should be secured as soon as possible after the injury. In military surgery this rule cannot be generally applied, and an anomaly in surgery thus arises. The author is led to discuss the methods by which Nature controls the bleeding from arteries thus injured. The vessel may be occluded primarily by provisional thrombus, and the wounds in the vessel may cicatrize. This has been observed post-mortem in the superficial femoral fifteen days after injury in a case in which the patient died of typhoid fever, and in the abdominal aorta in a case in which the patient died seventy days later from subphrenic abscess. Adhesion of the vessels and nerves may provide another means of occlusion. Spontaneous cure may be the end result of hematoma due to injuries to arteries, of contraction to form circumscribed traumatic aneurysms, and, eventually, of consolidation. The development of pure aneurysmal varix is regarded as another of Nature's methods of cure; it is a permanent arrest of hemorrhage by a spontaneous process of healing. The difficulties of treatment are considerable. Primary ligature is the only operation which can be performed on the field, and it is limited to cases in which hemorrhage is endangering life. The results of primary suture of the injured artery have so far not given much ground to hope that this method of treatment, which may be considered the ideal, can be applied, chiefly because of the length of time which must elapse before the patient can be brought to a hospital where an operation demanding such delicate manipulations is possible, and also because of the nature of the injury to the wall of the vessel, and the accumulation of blood clot around it. In military surgery the treatment of secondary results of wounds of arteries is of chief moment. That is to say, not the wound of the artery itself but its sequela—arterial hematoma, traumatic aneurysm, arteriovenous aneurysm, or aneurysmal varix—has to be dealt with. Arteriovenous aneurysm is a surgical condition known from antiquity, but it has been enormously increased in frequency in modern times by the employment of the small caliber bullet. The author discusses five methods of treatment, each of which has its own suitability. His general conclusion is that progress in the branch of military surgery concerned with arterial wounds by bullets of small caliber is in the direction of greater conservatism and more watchful expectancy—an experience similar to that with regard to injuries caused by the same agents in bones and nerves and in the abdomen.

**3. Oil-Ether Anesthesia.**—By J. T. Gwathmey. (See MEDICAL RECORD, Vol. 84, pages 1082 and 1138.)

**6. Vaccines Graduated by Their Opacity.**—L. C. Bruce has devised a method of graduating vaccines by their opacity instead of by counting the microorganisms. The results of treatment have been equally satisfactory, and the labor has been reduced to a minimum. His method is to grow the cultures on agar, blood agar, etc., and to make an emulsion of the growth with normal saline. The emulsion is then placed in a ⅝th inch test-tube and diluted with normal saline until it is possible to read clearly certain type through the medium of the tube containing the emulsion. The type he employs as a meter is the ordinary type of Muir and Ritchie's "Handbook." The vaccine is then sterilized by heat or it is sterilized by chloroform or by ether. Satisfactory results were obtained by all three methods of sterilization. If the vaccine is to be used by the author he uses it in the above density, making the initial dose in every case 0.1 c.c. If the vaccine is to be used by a general practitioner the author dilutes the original emulsion to 2½ or 5 volumes, and the dose will

then be either 0.25 or 0.5 c.c. Subsequent doses can be increased or diminished according to the reaction obtained from the first injection.

*December* 20, 1913.

1. Injuries of the Arteries. G. H. Makins.
2. Typhoid-Paratyphoid Vaccination with Mixed Vaccines. A. Castellani.
3. Typhoid Cholecystitis. E. Morison.
4. A Case of Hysterical Monoplegia Following Electric Shock. P. Stewart.
5. A Case of Gastric Tetany; Recovery. W. T. Mills.
6. A Case of the So-called Rat-bite Disease. M. I. Diek and W. J. Rutherford.

**2. Typhoid-Paratyphoid Vaccination with Mixed Vaccines.**—A. Castellani concludes from his experiences with this method that in the use of the mixed typhoid + paratyphoid A +paratyphoid B vaccine, either the dead or the live (attenuated) one, is harmless. As there is such a general objection to the use of live vaccines, the author now recommends for routine use the mixed dead vaccine, which consists of an emulsion of typhoid and paratyphoid A and B bacilli, killed by heat (53° C.) and standardized, so that 1 c.cm. contains approximately 500 million typhoid bacilli and 250 million each of paratyphoid A and B. The inoculation of human beings with the above vaccine in doses 0.6 c.cm., the first time, and 1.2 c.cm. the second, induces a production of agglutinins for all three germs: *B. typhosus, B. paratyphosus* A, and *B. paratyphosus* B. The amount of agglutinins elaborated for each germ seems to be practically the same as in individuals respectively inoculated with typhoid vaccine only, paratyphoid B vaccine only, paratyphoid A vaccine only. In countries in which, besides typhoid fever, there occur paratyphoid A and paratyphoid B, a mixed vaccine should be used instead of the simple typhoid vaccine. This has been done in Ceylon for the last five years with good results.

**3. Typhoid Cholecystitis.**—A. E. Morison notes that it is not so generally known that inflammation of the gall bladder without stones may produce the same symptoms and signs. It is important to bear in mind that there may be no history of typhoid fever, and no record of any exposure to infection, and yet typhoid cholecystitis may be the cause of a serious illness. It is also important to remember that the illness may be a source of danger to the patient, and that as a typhoid carrier he may be a menace to the community for several years. Unfortunately in many cases of this kind a definite clinical diagnosis cannot be arrived at, because the Widal reaction may be negative, and the cause of the cholecystitis can only be cleared up by operation and subsequent bacteriological examination. The condition has been diagnosed as gallstones, but on opening the gall bladder none are found, only an inflamed mucosa. Simple drainage (cholecystostomy) does not always cure; after it the symptoms subside for a time, but the drainage wound closes, attacks recur, and the only effectual cure may be removal of the gall bladder.

**Contact Infection in the Epidemiology of Cholera.**—Eckert has studied this malady during the Balkan wars with the following conclusions: That cholera may originate "explosively" as a result of the contact of many people is shown in the epidemic at Tschataldscha. On the other hand, at Sofia, with its sanitary precautions and cholera hospitals, there was no contact infection among the attendants, despite the lack of personal hygiene in the latter. Flies seem to play no part in transmission. In order to explain contact infection whenever this occurs, the author can do no more than guess that ordinary vibriones occur here in an actively virulent form, no separate causal element playing any rôle. Hence, despite sanitary prophylaxis, we must always bear in mind that the possibility of contact infection can never be left out of sight. It is possible also that fear of infection plays a part here. Suppose that the wounded develop cholera when under treatment, should a special station be set apart for such cases? The answer is no, beyond a ward or pavilion in a general field hospital.

**Pock Exciters.**—Fornet insists that despite all apparent recent progress in this field the cause of variola is still unknown, although carriers of the parasite may be in evidence in various bodies. He repeats the various modifications of technique, the ether addition, new stains, etc. Something has been cultivated which seems to be able to cause certain phenomena seen with variola, but we cannot produce from this a separate lymph. These "single and double formations" cannot be made responsible for the production of variola or vaccinia. Other minute forms must exist which perhaps are definitely related to the larger bodies, as a developmental form. These larger structures, which the author terms "microsoma variolæ," have long been known—for ten years at least they have been described under different names. They do not answer to Koch's requirements as a cause of disease, and thus cannot be set down as the cause of variola.

**Vaccinotherapy of Cancer.**—Blumenthal believes that malignant tumors may be favorably influenced by vaccines, which introduce new progressive concepts of cancer therapy. This is an element which, like several others, is encouraging. The idea must be greatly expanded. A desideratum is the treatment of one's own tumor by products of its own, yet without exposing the growth to infection. An entire tumor may be extirpated and vaccines prepared to inoculate against recurrence. Generally a serum must be made from a tumor in a second person and having the same nature. Lunckenheim has prepared tumor extracts which have given positive clinical results.

**Chemical Constitution and Physiological Action.**—Langgaard makes no reference to the monumental work of Fraenkel in this field. He gives numerous examples in which members of a series produce different physiological results. Every student of new synthetic drugs is assured that this relationship acts throughout in building them up. We may select a few cases of the author: thus caffein = trimethylvanthine in various groupings. It excites the cerebral cortex, heart, and kidneys. Theobromin = dimethylvanthine acts only on the kidneys, as does only theocine. In coffee is the xanthin base; three methyl units are bound by ammonia in three different portions of the molecule. In theobromin and theocoll two units of methyl are bound to the xanthin in different portions of the molecule. The $CH_3$ group is recognized in caffein by the figures 1, 3, and 7; theobromin by 3 and 7; theocoll 1, 3. The much greater power of caffein is therefore bound up in the extra methyl unit.

### Münchener medizinische Wochenschrift.

*December* 2, 1913.

**Radiology and Chronic Appendicitis.**—Singer and Holzknecht sum up their study as follows: The appendix itself is not represented, and its course is fixed only through the situation of the conducting organs, checked up by the character and direction of the pain. Hence in painless intervals we cannot carry out the method so

that the utilization of the method is restricted to the algid (?) stage. We nevertheless believe that in the diagnosis of important diseases of the right iliac fossa we have introduced a new and fairly accurate resource which seems suited to remove the obscurity heretofore attendant upon methods and judgment. The method should prove of especial value in pseudo appendicitis and simulation.

**Plumbing Tuberculous Lungs.**—Gwerder has made a short priority claim in regard to some work done in his sanitarium at Arosa. The author states that when compression therapy by artificial pneumothorax cannot be carried out, we have pneumolysis or Baer's plumbing to fall back on, before we have to perform a thoracoplasty. Mere pneumolysis has no great merit, and Baer's resource is of a character too localized. The author has been at work since Baer's publication in animal experiments in the same direction, but substituting for solid plumbing the use of air, introduced in bags. The pressure may be varied, and the apparatus has no weight. The process need not be limited to small superficial cavities, for the rubber balloon, when inflated slowly, will adapt itself to the compass of any cavity.

**A New Type of Typhus in East Asia.**—Furth, who is stationed in China reports an episode which tends to bear out Naunyn's recent claim that typhus is more a syndrome than a disease. In the group of six cases treated, the exciting cause appeared to be the usually saprophytic bacillus fecalis alkaligenes. Ordinary typhoid was readily excluded. The bacillus just named was found in the blood and intestinal discharges. The patients were sailors on the same vessel. The symptoms which ushered in the attack were violent headache and pain in the limbs with great fatigue. Fever of 39° C. Aside from a slight pharyngeal congestion there were no local symptoms whatever. The pulse was accelerated, but the heart and blood-picture unaltered. There was barely a leneocytosis. The urine gave a positive diazo but nothing further abnormal. The fever curve showed great variation but was of the same type for all. All patients recovered unharmed, save one left with myocarditis. An exanthem is not mentioned and Naunyn implies that the existence of one is not indispensable. Neither are sopor and apathy mentioned, perhaps because of the benign character of the episode. The febrile period extended between three and four weeks, and two patients had a relapse. Naturally the *B. fecalis alkaligenes* may have been associated in the blood with an invisible causal germ, and may have simply played a saprophytic role save that its liberated endotoxins may have modified the disease picture.

**The Active Ingredient of Beek's Bismuth Paste.**—Wacker takes part in a small controversy which is in progress just now in Germany. Recently Rost advanced the opinion that the paraffin alone was responsible for the round granulation. To test this theory the author has made some experiments as a result of which he finds that certain raw paraffin oils obtained from brown coal tar stimulate epithelization. This of course leads one to recall the paraffin epithelioma, which, however, results only from many years of continuous irritation. It can also be shown that ordinary petrolatum and lard are actually healing, *i.e.* granulating (experiments on the rabbit's ear). The active constituents of these oils and fats are doubtless present in minute amounts, suggesting hormones.

## Deutsche medizinische Wochenschrift.

*December* 4, 1913.

**Tabes in Brazil.**—Austregesilo of Rio, after discussing typical tabes and the incipient and few symptom form sums up as follows: Tabes is common in Brazil, as elsewhere where the world is thickly populated. The factors of race and climate do not seem to exert any influence on this frequency. Incipient tabes is of course common and passes into the classic type, while "few symptom" tabes never shows but few symptoms. There is no monosymptomatic tabes. One symptom can as most suggest pretabes. Tabes is a quarternary syphilitic affection, an electric fiber disease of the posterior columns. Early diagnosis is necessary for then Hg and salvarsan can abort the condition. General and physical therapy must back up the specific.

**Exanthematic Typhus.**—Naunyn believes this to be a collective term, which indicates several distinct members. Naturally we could not form a distinct conception of this affection until abdominal typhus had been thoroughly dissociated from it. In fact our knowledge of the spotted typhus as an entity dates only from 1849, and is not necessarily the terrible typhus of the Napoleonic wars. The two new diseases were studied side by side. In the author's time they were badly confused, autopsy results giving the lie to diagnosis. Critically speaking there are no post-mortem appearances which characterize typhus. Much stress was laid on the quality of the rash *intra vitam*, and this exhibited great fluctuations (maculæ, petechiæ, marmorisation). Many acute infectious diseases present a picture not unlike typhus, as Weil's disease, certain cases of malaria, Brill's disease, Manchurian typhus, etc. Brill's disease is especially instructive, as illustrating the impossibility of separating it wholly from true typhus, tabardillo, etc. In times of great epidemics typhus and the bubonic plague behave in much the same manner. Indeed judging only from this behavior one might decide that they represent one and the same epidemic. This view was expressed by Murchison many years ago who added that spotted typhus played the very same role in the temperate zone that bubonic plague did in the tropics. We have not yet found the germ of any of the typhuses; and when we do, should not be surprised to find several of different sorts. In any case the author feels confident that ultimately "typhus exanthematicus" and "fleckfieber" will disappear from our nomenclature.

**Pneumococcus Influenza.**—Walb takes up this subject purely from the clinical aspect. Influenza and pneumonia flourish at times side by side, and in some epidemics of influenza the mortality from pneumonia is high. It is commonly held that the latter furnishes an ideal soil for the former. A number of epidemics of influenza have shown the absence of the specific cause, and instead the presence of the pneumococcus. Some authorities simply call the latter pseudo-influenza and point out clinical differences, notable the incubation stage which in true influenza is extremely brief. Influenza proper may attack the entire organism, while false influenza is localized to the respiratory tract. Influenza crops out at times in all parts of the world as a pestilence, while false influenza is perennial.

---

**A New Operation for Edema and Varicosities of the Lower Limb.**—Guiseppe D'Oria has adopted a suggestion made by Biondi, of Siena, that a new operative method of treatment be utilized in the case of edema and varicosities of the lower limb resulting from thrombosis of the femoral or iliac vein, such as occurs in typhoid fever and other infectious processes. The principle of the method consists in reducing the afflux of blood to the limb in proportion to the reduction of its efflux. This is accomplished by the simple technique of applying a double ligature to the superficial femoral artery. This interruption to the superficial circulation of the lower limb results in a diminution of the edema and a disappearance of the varicosities.—*La Riforma Medica.*

## Insurance Medicine.

**A Few Remarks on Blowing Heart Sounds and Their Significance for Insurance Practice.**—Dr. Goliner of Erfurt refers to the frequency with which cardiac murmurs are erroneously called "accidental," "anemic," "chlorotic," etc. The diagnostician often overlooks the fact that the rhythm of the heart may often determine the presence of respiratory sounds which simulate cardiac blowing murmurs and are, in fact, blowing murmurs which greatly resemble those due to organic heart disease. Yet differentiation is not difficult here. In 1894 l'otain first called attention to these cardiopulmonic murmurs, and emphasized the differential points. Sounds of all kinds are best differentiated by their seat and rhythm, and this generalization is easily recognized in cardiopulmonic sounds. These may be heard at two points, both coming under the head of basic cardiac sounds, viz.: the origin of the aorta and the origin of the pulmonary artery. In addition they may be heard over the median cardiac auscultatory zones, left ventricle only. In the apical area cardiopulmonic sounds are never heard, which might suffice to exclude them but for the fact that the apex is the seat of many organic murmurs. It can be shown that the vesicular murmur of the lungs can be transferred to the heart, the rhythm of which seemingly converts them into heart murmurs. Nothing seems more simple, yet the behavior of the heart and lungs in special cases may give great variation to the murmurs. They may appear and disappear, and change daily their kind, rhythm, tone, etc. Thus the first examiner notices a blowing murmur, while another, later, hears nothing. A murmur can pass from one ausculatory zone to another. Inorganic murmurs are often distinguished from the organic type by mere change of position. This should be tested fully in suspected cardiopulmonic murmurs. H. Müller of Zurich believes that many subjects rejected for insurance on account of organic heart disease are in reality victims of false diagnosis (see his monograph, Über accidentelle Herzgeräusche," 1907). The time will doubtless come when "cardiopulmonic" and other "accidental" sounds will be readily recognized by the examiner. But what course will be taken by the companies cannot now be foreseen.—*Blätter für Vertrauensärzte der Lebensversicherung*, May-June, 1913.

**Altruistic Selfishness as Exhibited in Life Insurance Work.**—The activities of the life insurance companies in the conservation of the lives of their policyholders have been somewhat cynically described as "altruistic selfishness." So far as the public and the policyholder are concerned, it is enough for them to know that the end results are altrustic—they can well afford to forget the alleged selfishness. Business selfishness that strives to prevent human misery and premature death is not exactly a destructive force in the community. Furthermore, those who commence this work in a spirit of selfishness haply may have some of the dark corners of their minds opened up and ventilated as they gain a knowledge of the extent of human suffering and of the stupid, pitiable social misrule which permits it to continue, generation after generation; the same old aches and pains, the same old physical and mental miseries and inefficiency; the same old futile charities that utterly fail to lift the burden of accomplished evil. Eugene Fisk, Medical Director, Postal Life Insurance Company, thus succinctly presents the situation and further says that during many years of contact with business men, he has become impressed with the fact that sympathy for human suffering is such a common, normal trait among them as to render its absence the mark of a detective, using the term in a pathological sense. In many people the feeling is not strong enough to move them to self-denial, or to any great amount of effort for human betterment, but certainly in the average man it is strong enough to give him a sense of satisfaction if the successful development of his business provides a vehicle for the relief or prevention of sickness and suffering. Altruistic selfishness, so called, is not confined to the life insurance business, where it is merely in a first stage of development. Employers of labor are discovering that the human machine, if well cared for, works with greater energy and precision and turns out a better product. There is a great hope for mankind as these simple truths slowly filter into the minds of practical men of affairs. When "big business" moves naturally along lines that make for health and well-being in the community, much of the sordid misery that is a reproach to our civilization will disappear and with it the quack, charlatan, and vendors of nostrums, whether political, medical, or social, who exploit humanity's ills.—*Lancet-Clinic*, August 9, 1913.

**Medical Conditions Encountered in Egyptian Insurance.**—Dr. Day shows that the only serious endemic diseases that attack the European residing in Egypt are typhoid fever with its congeners and dysentery. The possession of trained servants and the habitual observance of due precautions are necessary safeguards against oral infections, while the rapidly growing practice of typhoid vaccination has diminished the incidence and virulence of this disease. Sufferers from chronic lung or joint trouble, who have settled in Egypt for the sake of their health are generally ineligible for insurance at home, but when all signs of disease have disappeared, they may ultimately be accepted for a limited term. The common diseases of Western Europe are equally important in Egypt. Rheumatic fever, tuberculosis, and syphilis—the three most important for life insurance—are as frequent as at home. Syphilis is spoken of without shame, the affection being referred to the father or mother of the patient equally indifferently. The native adult has little susceptibility to typhoid, having been protected by an attack during infancy or childhood. Appendicitis and carcinoma are still relatively rare compared with their incidence in England; diabetes is much more frequent. Most tropical diseases are endemic in Egypt, but are largely avoided by personal cleanliness and sanitation. Ankylostomiasis, pellagra, splenomegaly (Banti's disease), relapsing fever, and typhus, although common among the peasantry, rarely attack a member of the upper classes. In boyhood, bilharziasis is often contracted, but the severe cases are only seen in the field workers who are exposed to repeated infection. A slight lesion of the bladder wall, but without obvious hematuria, does not endanger life, provided a fresh infection can be excluded. Attacks of renal colic in Egypt are frequently due to bilharzial disease of the ureters without the presence of calculi. Provided the attacks have not recurred since early manhood, and no signs of bilharzial disease remain, such cases may be accepted. Life Assurance Medical Officers Association, May 7, 1913.

# Book Reviews.

MEDICAL ELECTRICITY. A Practical Handbook for Students and Practitioners. By H. LEWIS JONES, M.A., M.D., Fellow of the Royal College of Physicians of London; Consulting Medical Officer to the Electrical Department in St. Bartholomew's Hospital; Honorary Fellow of the American Electrotherapeutic Association; Member of the Société Française d'Electrothérapie et de Radiologie; Associate of the Institution of Electrical Engineers. Sixth edition, with illustrations. Price $4 net. Philadelphia: P. Blakiston's Sons & Co., 1913.

THE author comments in his preface to this edition on the recent changes in conceptions of medical action of electricity. The subject of $x$-rays in diagnosis has also increased in importance and he only attempts to give an introduction to special works. There are new paragraphs added to this edition on anions and kathions, on Leduc's apparatus for interrupted currents, Finsen's lamp, Cooper Hewitt's lamp, Kromayer's quartz lamp, multostats and polystats, mercury jet break, diathermy, stereoscopic work, ionic medication, condenser discharges, Sprengel's deformity, $x$-rays in anterior poliomyelitis, paralysis agitans, acromegaly, Raynaud's disease, intermittent claudication, asthma, rectal fissure and ulceration, esophageal spasm, gonorrhea, amenorrhea, dysmenorrhea, endometritis, vaginitis, uterine fibromyoma, ovarian neuralgia, vomiting of pregnancy, parturition, the mammary glands. There is an additional chapter on the affections of the joints and the fibrous tissues, and ocular and auricular disorders have now a separate chapter. Two appendices, a table of electrochemical equivalents and of relative ionic velocities, together with a list of towns giving the character of their electric supply, complete this extremely useful manual. There are thirteen more anatomical plates illustrating the applications of electrical treatment described in the text.

THE ELEMENTS OF BACTERIOLOGICAL TECHNIQUE. A Laboratory Guide for Medical, Dental, and Technical Students. By J. W. H. EYRE, M.D., M.S., F.R.S. (Edin.). Director of the Bacteriological Department of Guy's Hospital, London, and Lecturer on Bacteriology in the Medical and Dental Schools; formerly Lecturer on Bacteriology at Charing Cross Hospital Medical School, and Bacteriologist to Charing Cross Hospital; sometime Hunterian Professor, Royal College of Surgeons, London. Second edition, rewritten and enlarged. Price $3. Philadelphia and London: W. B. Saunders Co., 1913.

IN this volume the reader finds the usual bacteriological procedures described and illustrated without any attempt to depart from the field of actual technique. Every laboratory worker needs some such book as a working guide and the present one may be recommended as well adapted to fulfill this particular object. The illustrations are both numerous and good and the text for the most part is satisfactory. In this edition various new methods have been added, but it is not quite clear why the technique of the Wassermann reaction has not been included, for although the determination of the opsonic index, for example, is described, and there is a brief account of the method of performing complement fixation tests in general, the actual application of this principle to the diagnosis of syphilis is not given.

ESSENTIALS OF PATHOLOGICAL CHEMISTRY, INCLUDING DESCRIPTION OF THE CHEMICAL METHODS EMPLOYED IN MEDICAL DIAGNOSIS. By VICTOR MYERS, M.A., Ph.D., Professor of Pathological Chemistry New York Post-Graduate Medical School and Hospital, and MORRIS S. FINE, Ph.D., Instructor in Pathological Chemistry, New York Post-Graduate Medical School and Hospital. Price $1.25. New York: The Post-Graduate Medical Journal, 1913.

WHILE the present volume is not very large, it summarizes conveniently so much of the recent work on metabolism that it must be regarded as an important addition to the list of books on laboratory diagnostic methods. The subjects covered are gastric and intestinal digestion; the physical properties of urine; albuminuria, glycosuria, and other types of mellituria; acidosis; pigmenturia; urinary sediments; the chemistry and physiology of milk; blood and other fluids. These separate chapters appeared at intervals during the past year in the Post-Graduate and have now been assembled in book form together with an appendix devoted to general laboratory suggestions. Under each heading there is given first a general discussion of the subject in question, followed by working directions for carrying out the various laboratory procedures involved. These are thoroughly modern and many of them have not yet found their way into the ordinary textbooks; for example, there are given Rose's method of pepsin determination, a newly modified test for beta-oxybutyric acid, methods for blood sugar and for amino acids, Folin's microchemical methods for blood and urine, etc. The only criticism to be made is that the authors have, if anything, erred on the side of conciseness, so that some of the procedures described could hardly be carried out successfully by a beginner without more detailed directions than those provided. The book could advantageously be somewhat enlarged in subsequent editions for, as is unavoidable, many things of interest have, perforce, been omitted. For example, the phenolsulphonephthalein test is the only one mentioned for the purpose of estimating renal efficiency.

DIE GESCHWÜLSTE DER HAUTDRÜSEN. Von Prof. Dr. G. RICKER, Leiter der pathologisch-anatomischen Anstalt der Stadt Magdeburg, und Dr. JOHANNES SCHWALB, Assistent. Mit 13 Abbildungen im Text und auf 5 Tafeln. Price 10 marks. Berlin: Verlag von S. Karger, 1914.

FOR many years there has been a discussion on the nature of certain rare tumors of the skin. They have been called adenomata sebacea, multiple benign cystic epitheliomata, epitheliomata adenoides cysticum, syringomata, syringocystadenomata, endotheliomata, etc. Numerous articles describing individual observations or small collections of cases have appeared from time to time, without clarifying the situation. The difficulty lies in the impossibility of recognizing on microscopical examination of a well-developed growth the source or organ from which the epithelial cells of the particular tumor are derived. The dermatologist, however, has an unusual opportunity to see benign and malignant tumors during their earliest period of development and most of the studies have emanated from workers in that field. Unfortunately absolute uniformity has not been reached, either as to nomenclature or as to classification, nor does the monograph before us add any great clarity to the topic. There is a good deal of discussion of a polemic nature, especially in the conclusions, which might well have been omitted. The first 180 pages are devoted to a description of twenty-four personally observed cases of epithelioma of the sweat and sebaceous glands. It is unfortunate that the word epithelioma is used in this connection, because these tumors in most instances lack any quality of malignancy which that term connotes to the surgical mind. In consequence, many of the magic effects of radium which have been so widely heralded in the daily press are observed during the treatment of these, in many cases, perfectly benign "epitheliomata." A series of five fairly good plates with ten figures illustrate some of the varieties of tumors which the authors have considered in their text. While an enormous amount of labor has been spent in collecting this material, it is still perfectly evident that the question of the exact origin and nature of these tumors is not at all settled, and that there is room for a good deal more investigation.

THE PRACTICAL MEDICINE SERIES. Comprising ten volumes on the Year's progress in Medicine and Surgery. Under the general editorial charge of GUSTAVUS P. HEAD, M.D., Professor of Laryngology and Rhinology, Chicago Post-Graduate Medical School. CHARLES L. MIX, A.M., M.D., Professor of Physical Diagnosis in the Northwestern University Medical School. Volume II. GENERAL SURGERY. Edited by JOHN B. MURPHY, A.M., M.D., LL.D., Professor of Surgery in the Northwestern University, Attending Surgeon and Chief of Staff of Mercy Hospital, Wesley Hospital, St. Joseph's Hospital, and Columbus Hospital, Consulting Surgeon to Cook County Hospital and Alexian Brothers' Hospital, Chicago, Ill. Series 1913. Price $2. Chicago: The Year Book, Publishers.

THIS volume recounts the past year's work in surgery. It treats of diagnosis and improved operative technique, new instruments and rare surgical cases. Considerable stress is laid on refinements in surgical technique and in experimental surgical work. The volume should prove of special value to the surgeon.

The Practical Medicine Series. Comprising Ten Volumes on the Year's Work in Medicine and Surgery. Under the general editorial charge of Charles L. Mix, A.M., M.D., Professor of Physical Diagnosis in the Northwestern University Medical School. Volume V. Pediatrics, Edited by Isaac A. Abt, M.D., Professor of Pediatrics, Northwestern University Medical School, Attending Physician Michael Reese Hospital. Orthopedic Surgery, Edited by John Ridlon, A.M., M.D., Professor of Orthopedic Surgery, Rush Medical College. With the collaboration of Charles A. Parker, M.D. Series 1913. Price $1.35. Chicago: The Year Book Publishers.

Many interesting pediatric cases reported during the past year are here recorded. Mention is made of the valuable points that have been gained from a study of the work of the Infant Welfare Association and Boards of Health in their effort to reduce infant mortality. The section devoted to orthopedics is a helpful résumé of the literature of the past year on the subject.

Mechanical Treatment of Abdominal Hernia. By William Burton De Garmo, M.D., Professor Special Surgery New York Post-Graduate Medical School and Hospital, Fellow New York Academy of Medicine, Member of the American Medical Association, New York State and County Societies; Honorary Member of the Medical Society of Virginia, Member of the Clinical Congress American Surgeons, First Lieutenant Medical Reserve Corps, U. S. Army. Price $1.50. Philadelphia and London: J. B. Lippincott Co., 1913.

This little book is intended as a guide in the selection and fitting of trusses and especially as an aid to those who have no interest in the surgical side of the subject. For the hundreds of men who are doing truss fitting and who are not medical men this work has been prepared in response to repeated requests from them. It is hoped that these truss fitters will find this work useful and suggestive and that it will lead to more intelligent work. No attempt has been made to deal extensively with the anatomy or pathology of the hernia. The main chapters deal with the mechanical treatment of each of the following: 1. Inguinal hernia. 2. Irreducible inguinal hernia. 3. Inguinal hernia in infancy and childhood. 4. Femoral hernia. 5. Traumatic ventral hernia.

Gout, Its Etiology, Pathology, and Treatment. By James Lindsay, M.D. (Edin.), M.R.C.P. (Lond.), Hon. Physician, Formerly Hon. Pathologist and Res. Med. Officer Royal Mineral Water Hospital, Bath. Price $1.50. London: Henry Frowde. New York: Oxford University Press, 1913.

The object of this small book is chiefly to present to the profession the results of the author's observations in the study of about 600 cases of gout. The list of the cases comprises those admitted to the Royal Mineral Water Hospital during the past six years. The book contains excellent photographs and skiagraphs. The chapters are systematically arranged beginning with the etiology of gout, continuing on through morbid anatomy and pathology, symptoms and forms, differential diagnosis, and concluding with the treatment of this disease.

Hemocytes and Hemic Infections. A Hand-Book for Students and Practitioners. By Frederick W. E. Burnham, M.D., C.M. With 226 microphotographs by the author. Price $6. New York: E. B. Treat & Company, 1913.

The illustrations are the most striking feature of this volume on the blood and blood diseases. They are all photomicrographs of very high magnification and show the defects to be expected in the use of even the best of lenses to give magnifications larger than they were designed to yield. The author has included many parasites which are of no interest to the medical student, such as, for example, a long series of pictures and descriptions of the various trypanosomes found in the batrachians, birds, rats, and domesticated animals. He disarms criticism by a frank statement in his introduction that the volume is without pretension to being a complete treatise, and was written merely to furnish information to the student and general reader on parasites and diseases of the blood.

Collected Papers from the Research Laboratory Parke, Davis, and Company. Vol. I. Detroit, 1913.

This book consists of thirty papers collected from articles published in English, German, and American medical, veterinary, and other scientific journals. Most of the articles are accompanied by charts and illustrations. The titles of some of the papers are as follows: 1. Administration of diphtheria toxin in a collodion sac. 2. Insecticides—fumigants. 3. Etiology of canine distemper. 4. Soaps from different glycerides. 5. Sleepy grass of Mexico. 6. Depressor action of pituitary extracts. 7. Catgut and sterilization. 8. Serum treatment of hemorrhage and blood dyscrasias. 9. Pharmocological requirements for cannabis sativa. 10. The heart tonic unit. 11. Bacteriological standardization of disinfectants. 12. Tobacco extracts; their comparative values as insecticides. 13. Pituitary extract in obstetrics and gynecology, et al.

A Code System for the Hospital Pathological Laboratory. Part I. Autopsy Work. Being a student's guide to the description of autopsy organs. By O. C. Gruner, M.D. (Lond.), pathologist to the Royal Victoria Hospital, Montreal. Price 65 cents. Toronto, 1913.

While anything which will lighten the labor of recording autopsies may be of interest, it is very questionable whether a code system of numbers, as suggested in this pamphlet, is of value. Its use would result in a very much compressed autopsy protocol, but also in one which, if the code were unknown, would be absolutely useless from a medicolegal standpoint. To the reviewer this supposedly labor-saving device seems to be one of those which increases rather than diminishes the difficulties of hospital records.

Traitement de la Syphilis par le Serum Organique du Dr. L. C. Query. Observations Cliniques. Paris: Laboratoire de Serotherapie Specifique et de Microbiologie, 1913. Price 2 francs.

The appearance of this little volume is opportune; it draws attention to the importance of serum therapy in the treatment of syphilis, and it shows how some of the more important sequelæ of this disease may be prevented.

The Wellcome Photographic Exposure Record and Diary. 1914 U. S. A. Edition. Price 50c. London: Burroughs, Wellcome & Company, 1914.

The edition for the coming year of this well-known exposure record contains a considerable amount of new matter in regard to recent improvements in developing technique, color photography, etc. Especially full directions are given for producing colored effects in the development and toning of prints and transparencies. All of the tabular information of the previous editions has been retained and the usual exposure meter is still to be found at the back of the volume. For the benefit of those not already familiar with the little book it may be said that it represents one of the greatest conveniences the amateur or professional photographer can have.

Progressive Medicine. A quarterly Digest of Advances, Discoveries, and Improvements in the Medical and Surgical Sciences. Edited by Hobart Amory Hare, M.D., Professor of Therapeutics and Materia Medica in the Jefferson Medical College Philadelphia, assisted by Leighton F. Appleman, M.D., Instructor in Therapeutics, Jefferson Medical College, Philadelphia. September 1, 1913. Price $6.00 per annum. Philadelphia and New York: Lea & Febiger, 1913.

The current issue of this valuable quarterly is on the same lines as heretofore, and contains four sections, each giving a most useful summary of the recent advances in some special branch of medical science. Dr. W. Ewart is responsible for the section on diseases of the thorax and its viscera, including the heart, lungs, and blood vessels. Dr. W. S. Gottheil contributes the section on dermatology and syphilis. The chapter on obstetrics is by Dr. E. P. Davis, and that on diseases of the nervous system by Dr. W. G. Spiller.

A Compend of Diseases of the Skin. By Jay F. Schamberg, A.B., M.D., Professor of Diseases of the Skin, Philadelphia Polyclinic and College for Graduates in Medicine; Fellow of the College of Physicians of Philadelphia; Member of the American Dermatological Association. Fifth Edition, Revised and Enlarged, with 112 Illustrations. Price, $1.25. Philadelphia: P. Blakiston's Son & Co., 1913.

This new edition is longer than its predecessor by about two pages, these pages being taken up with a brief account of the salvarsan treatment for syphilis and the use of carbon dioxide and vaccines in the treatment of skin diseases.

# Society Reports.

## NEW YORK ACADEMY OF MEDICINE.

SECTION ON MEDICINE.

*Stated Meeting, Held October 21, 1913.*

DR. LINSLY R. WILLIAMS IN THE CHAIR.

THE communications were from the medical wards of the Montefiore Home and Hospital.

**Case of Auricular Fibrilation in a Child.**—Dr. S. G. EHRENREICH presented this case. He said that a certain type of irregularity of the heart was so common in childhood as to be designated the youthful type, that was, the sinus form of arrhythmia. Extrasystoles were also found, and heart block, though rare, had been described repeatedly during the course of diphtheria and acute articular rheumatism; certain cases of heart block had been attributed to previous diphtheria. Perpetual arrhythmia was so rare that up to the present time he knew of no case that had been reported as occurring in a child under thirteen years of age. The case presented was a typical example of auricular fibrillation which was first observed when the child was nine years of age. The characteristics of this condition were absolute irregularity of the heart action and of the pulse, the absence of any "A" or auricular wave in "A" the jugular portion of the polygraphic tracing, the absence of the "P" or auricular wave in the electrocardiogram, and the presence of the electrocardiographic curve of undulatory waves at the rate of several hundred per minute preceding the "R" or ventricular curve. Most of the cases of auricular fibrillation in younger adults occurred on the bases of an old rheumatic endocarditis, usually of the mitral valve; there was another group of cases of adults or older individuals in which the fibrillation occurred in hearts which were sclerotic. The patient presented was now ten years of age and was admitted to the Montefiore Home three and one-half years ago. Her family history revealed nothing of importance. She had had measles when two years of age and two or three attacks of pneumonia later, and an attack of influenza at the age of six years. For a week or so following she gave an indefinite history of acute articular rheumatism. Five months later cardiac palpitation and precordial pain appeared, followed a year later by dyspnea; since that time she had had a few attacks of cardiac decompensation but always recovered after complete rest in bed. On admission to the home her heart action was regular, there was dilatation of both sides of the heart, and a double mitral murmur was audible, with marked accentuation of the second pulmonic. On May 25, 1912, the patient had one of her decompensation attacks, when she was put on digitalis and complete rest in bed. At this time the pulse rate and heart action were still regular but two days later an arrhythmia was first noticed, and on taking the polygraphic tracings typical curves of auricular fibrillation were observed. This arrhythmia had apparently never been absent since.

Dr. T. STUART HART said he was very much interested in this case; he had never seen a similar one in a child so young.

Dr. LINSLY R. WILLIAMS said that they should always consider the possibility of an adherent pericardium in these cases of auricular fibrillation.

**Further Contribution to the Rigid Spine with Presentation of Two Cases of the Rhizomélique Type.**—Dr. GEORGE R. ELLIOTT presented this communication which was demonstrated with lantern slides.

**Congenital Pulmonary Stenosis with Electrocardiograms.**—Dr. B. S. OPPENHEIMER said that congenital stenosis of the pulmonary artery was clinically the most important and the commonest of all cardiac anomalies and was described as long ago as the time of William Hunter. With the introduction of the electrocardiograph and of the orthodioscope a renewed interest was being taken in congenital cardiac defects, in the hope that these newer methods would be of aid in diagnosing the lesions. A clinical case was presented in which an absolutely positive diagnosis of the congenital lesion could not be made. The patient was a spinster, 42 years of age, who had been in Montefiore Home for the past sixteen years and had been under observation in Bellevue Hospital for several years preceding. Her mother while carrying her was subjected to a severe fright during the fifth month of pregnancy. She was a so-called blue baby. Her chief complaints were hemorrhages from the lungs, nose, and bowels, dyspnea, palpitation, precordial pain, and dizziness. She showed only one other congenital malformation, that was, a bifid uvula. She had a marked cyanosis, clubbing of the fingers, a somewhat bulbous nose, and was rather stunted in stature. The physical examination of the heart showed an enlargement to the right. There was a palpable impulse at the base synchronous with the second sound. On listening to the heart over the apex both sounds were audible; and following the second sound, there was a rather faint diastolic murmur. Over the pulmonic area, the first and second sounds were present, the latter merging into a prolonged, loud diastolic murmur which in turn persisted until the first sound. Patient had a polycythemia; her erythrocyte count varied from 6 to 9 millions; hemoglobin was 100 to 125 per cent.; Systolic blood-pressure was 114 mm. The *x*-ray examination showed a dilatation of the pulmonary artery, but not any unusual pulsation such as had been found to be characteristic of cases with patent ductus arteriosis (Bass and Wessler). The case was considered one of congenital pulmonic stenosis with associated lesions, probably a septal defect, possibly patent ductus arteriosis or pulmonary insufficiency. The heart from a second case of pulmonic stenosis was presented. It was obtained from a boy eight years of age who during life had been deeply cyanosed and had marked clubbing of his fingers and toes. He had had rheumatoid pains in his ankles, and had had scarlet fever. The heart presented the typical combination of (1) stenosis of the infundibulum and of the pulmonary artery proper; (2) a patent septum ventriculorum; and (3) position of the aorta to the right. There was hypertrophy of the right auricle and of the right ventricle, the latter forming the apex of the heart. The foramen ovale was closed, but its membrane showed numerous fenestrations. The tricuspid valve, really bicuspid in this case, was stenosed and was lined with numerous vegetations; and it also presented hemorrhages which were situated rather on the auricular than the ventricular side of the cusps. There was only one cusp at the pulmonary orifice that could have functionated; the other one that was present was rudimentary. At the stenosis there was a vegetative arteritis, and distal to that the pulmonary artery was dilated and hypoplastic. The ductus Botalli was closed. The mitral and aortic valves were lined with vegetations. The aortic valve consisted only of two cusps instead of three. The cause of the vegetations on the valves could not be stated with certainty, as the rheumatic nodules described by Aschoff were not to be found, nor any evidences of malignant endocarditis in the kidney (Baehr) or other organs, and on staining the vegetations for bacteria a number of different organisms were found which had to be considered post-mortem invaders. The electrocardiograms of both cases gave the usual evidence of extreme right-sided hypertrophy. In addition in the first case the regular rhythm was interrupted by an occasional isolated premature beat which originated in the right basal portion of the ventricle. In addition in the second case, lead II was marked by a very high "P" wave which might be correlated with the hypertrophied right auricle. Both cases presented a striking amplitude of the electrocardiographic waves in the various leads, a phenomenon characteristic of congenital cardiac defects.

**A Study of Twenty-seven Cases of Advanced Pulmonary Tuberculosis Treated by Artificial Pneumothorax.**—Dr. LEO KESSEL and Dr. MAX TASCHMAN presented this paper. They stated that the advantages claimed for this method of treatment were: (1) The lung was immobilized. (2) New connective tissue grew in the atelectatic lung particularly around the bronchi and the vessels. (3) The tubercles were replaced by fibrous tissue. 4. Cavities collapsed and became obliterated. (5) Stasis in the circulation of the lymph set in, favoring a diminution in the degree of toxemia. (6) The total amount of blood in the lungs was reported to diminish but the experimental evidence for this finding was unsatisfactory. The twenty-seven cases, forming the basis of this report, were studied at the Bedford Hills Sanatorium of the Montefiore Home during the past six months. The observations were made during routine treatment. The patients were in all the cases in the third stage of the disease. In their procedure they gave the patients morphine (gr. ⅛ to ¼) and atropine (gr. 1/150 hypodermatically) with tincture of iodine and the excess was removed with 95 per cent. alcohol. The area was anesthetized with novocain (1 per cent.) and adrenalin (1-10,000 about one to two c.c.). The apparatus introduced by Floyd and Robinson was used together with the Floyd needles. A large caliber needle was employed for the first inflation and a small one in subsequent treatments. The patient was placed on his side on a pillow, to widen the intercostal spaces, and the skin was punctured and not incised with a fine cataract knife protected with adhesive plaster, to prevent injury and to avoid bleeding.

As the needle carrying the stilet was introduced through the anesthetized area into the pleural cavity the operator experienced a sense as of withdrawal of resistance and this sensation was quite characteristic. A water manometer was attached to the needle and when this was in place several readings were taken. When these were constant and the respirations regular, and when the oscillations in the manometer were free and the intrapleural pressure negative, nitrogen gas was permitted to flow. The rate was approximately 50 c.c. per minute. The intrapleural pressure was read after each 100 c.c. had entered. In the early cases the total nitrogen was 700 to 800 c.c., but later this was reduced to 300 to 500 c.c., and better results were obtained with the smaller amount of nitrogen. When the needle was withdrawn, the index finger of the opposite hand was pressed firmly over the site of the puncture and a pressure bandage was applied. This procedure prevented the occurrence of subcutaneous emphysema. The best area for the site of the injection was one most likely to be free from adhesions. The axilla was preferred because here the intercostal spaces were wide and there were fewer layers of muscle. The places to avoid were those over cavities, the precordium, the region of the large vessels, the breast tissue in women, and the region posteriorly below the ninth space. When pain and hyperalgesia were referred to the region of the shoulder on the side treated they formed a diagnostic point of much interest. Mackenzie had called attention to the fact that when the diaphragmatic pleura was irritated stimuli ascended from it by the phrenic nerves to the nuclei of the fourth and fifth cervicals. Nerves from these centers were distributed to the shoulders and it was to these that the pain was referred. He had observed the phenomenon in cases of diaphragmatic pleurisy. When complete collapse of the lung was established the physical signs underwent great changes. There was exaggerated breathing on the untreated side, but they had failed to note the disappearance of signs of consolidation mentioned by several observers. Râles became less marked or were absent and the signs of cavitation disappeared. To determine the presence of complete collapse by physical signs alone might be misleading, for many factors influenced the breath sounds in pneumothorax. Many complications had been reported as occurring during the production of artificial pneumothorax, among them pleural reflex, shock, or eclampsia, pain from direct injury of an intercostal nerve or one of its branches, subcutaneous emphysema, deep emphysema, blood stained expectoration due to puncture of the lung, rupture of the mediastinum with bilateral pneumothorax, of embolism, attacks of vomiting, or a small amount of pleural effusion. In only one instance did they encounter pleural reflex or eclampsia; this complication had been attributed by some to gas emboli, but this factor seemed to be excluded in their case. They had had no personal experience with deep emphysema. In a few instances they had encountered blood-stained sputum due to puncture of the lung but this disappeared promptly. In one instance there had been a rupture of the mediastinum with bilateral pneumothorax, but no untoward results ensued. They had had no personal experience with embolism and this complication was probably easily avoided by careful technique. In five cases they had observed a small amount of pleural effusion, which was always accompanied by a sudden rise of temperature to 102° or 103° F. and by pain in the side. The fluid aspirated from these cases was either straw colored and turbid or sero-sanguinous and showed a large number of lymphocytes. This fluid inoculated into guinea pigs produced tuberculosis. The contraindications to artificial pneumothorax included the following: (1) All cases in the first and second stages who were doing well under hygienic and dietetic treatment. (2) Cases exhibiting marked mental apprehension. (3) Patients who had chronic heart disease. (4) Patients who had definite intestinal tuberculosis. The indications for the treatment might be summarized as follows: (1) Extensive unilateral progressive cases who had failed to improve under hygienic and dietetic treatment. The earlier it was recognized that sanatorium treatment was useless the better the chance of succeeding with the pneumothorax treatment. (2) Extensive chronic unilateral cases who remained stationary and showed no constitutional symptoms but who were distressed by cough and excessive expectoration. (3) Cases of involvement of a single lobe containing a cavity. (4) Patients showing extensive unilateral progressive lesions but having small inactive involvement on the opposite side. (5) Bilateral cases having extensive lesions as shown by physical signs in whom the disease was slowly progressive, but in whom activity was limited to one side, the other presenting little, if any, activity. (6) Patients who had had repeated hemoptyses which did not cease under the usual treatment. Also those less frequent cases of large pulmonary hemorrhage in whom the loss of blood was great enough to warrant a fatal prognosis. (7) A group of cases included among those of advanced progressive tuberculosis in whom one must predict an early fatal issue. Under ordinary circumstances the indication of an artificial pneumothorax was here contraindicated, but a certain number of them by proper care and selection could be found who afforded gratifying improvement in very distressing symptoms where none had otherwise been possible. The clinical history of patients who had been favorably influenced by pneumothorax showed a decrease either abrupt or gradual in the temperature, a slowing of the pulse rate, disappearance of night sweats, improved appetite and digestion, and a feeling of improved general well being. The cough and expectoration in many cases were at first aggravated but after two or three days these symptoms decreased in severity or disappeared. It was noteworthy that no gain in weight commensurate with the amelioration of symptoms took place. Numerous observers had reported a marked diminution and in some cases a disappearance of the tubercle bacilli from the sputum but in our cases no appreciable change was noted. The promotion of fibrosis was best secured by the introduction of moderate amounts of the nitrogen gas frequently repeated, rather than with larger amounts at greater intervals. The most desirable condition was that in which a slightly positive intrathoracic pressure was maintained at all times. A study of the pleural adhesions in each case was important. The treatment should, therefore, be guided by studying skiagrams and *x*-ray photographs and by using the manometer during the induction of an artificial pneumothorax. The operation was usually devoid of danger if a careful technique was observed. A consideration of the physical signs alone yielded insufficient data to form the basis of treatment. In all cases of progressive pulmonary tuberculosis the induction of artificial pneumothorax should be considered. In hopeless cases it had been useful for it had brought remarkable relief from distressing symptoms, not obtained by any other measure.

Dr. Linsly R. Williams asked if they had ever seen in the treatment of these cases of pulmonary tuberculosis by artificial pneumothorax with nitrogen gas any of the old-fashioned hemorrhages coming on after ten or twelve hours.

Dr. Alfred Meyer said that he had never seen a case of hemorrhage occurring after the injection of nitrogen in cases of pneumothorax. Although an admirer of the antiseptic effects of iodine, in these cases he was inclined not to make use of this agent because it hid the pallor of the skin which indicated the appearance of anesthesia. In regard to the induction of pneumothorax the value of the manometer should be accentuated. It was the safest guide by its fluctuations as to whether the eye of the needle was in the pleural cavity. There should also be a limit to the number of punctures that were made. He recalled one case reported by a well-known sanatorium physician in which 2,000 c.c. of nitrogen escaped into space via the mouth because the needle was pushed through the pulmonary pleura and into one of the bronchioles. After the injection there was often a drop in the temperature of one or more degrees; and it remained at the lower level for a varying number of days, and then began to rise, and fall again with the next introduction of gas; after the first twenty-four hours there occurred sometimes an increase in the amount of expectoration as though a cavity or cavities or bronchiectases were being emptied more or less permanent, and then a decrease. The rule was that there was no gain in weight, rather a loss in weight, and with fever disappearing and symptoms improving this seemed a very strange anomaly. But there were exceptions to this rule also. Success in these cases depended largely upon the proper selection of the cases to be treated by artificial pneumothorax. For beginning the work in an institution he urged two points: selecting intelligent patients for cooperation, and selecting cases in whom a complete, rather than a partial, pneumothorax was probable. With regard to local anesthesia, Dr. Meyer stated that he never would make even an exploratory puncture of any human chest unless that chest was anesthetized down to and through the costal pleura. He said that he had been struck with the fact that so many cases of artificial pneumothorax did not show the classical signs; that hyperresonant note and decreased respiratory murmur were common, but amphoric breathing and voice less frequent.

Dr. S. Adolphus Knopf believed that in justice to the history of American medicine it should not be forgotten that Dr. John B. Murphy of Chicago produced artificial pneumothorax at about the same period as Dr. Forlanini. The operation was successfully performed a number of

times by Dr. Murphy, although without a manometer. Regarding the best method for the production of artificial pneumothorax Dr. Knopf stated that the authorities differed widely. There was the Brauer method, the Forlanini method, the modified Brauer method, etc. Dr. Knopf preferred the Forlanini method because the employment of a fine needle was safer. Even if lung tissue was penetrated with a small needle no great harm would result, and if by reason of multiple adhesions one had to make several punctures one was more sure to avoid infection. Ten minutes before the operation he gave the patient a hypodermic injection of morphine to allay apprehension and fear. Dr. Knopf believed that this might also help to avoid the much feared pleuritic shock. Prior to the insertion of the needle for the injection of novocain he used ethyl chloride. He considered the safer way to begin in all cases with the injection of 500 c.c. of oxygen gas and then follow with nitrogen gas. He answered the chairman's question considering a hemorrhage following the insertion of a needle by saying that it had occurred once in his practice without any serious consequences. Dr. Knopf thought the indications enumerated by the reader of the paper excellent and emphasized uncontrollable hemorrhage as one of the most important. In bilateral involvement with one side but little involved though possibly active, Dr. Knopf thought there were no contraindications. Dr. Knopf cautioned against the use of cold gas. He had devised a little lamp connected with a metal coil whereby the gas might be heated to body temperature by passing through the heated coil, thus avoiding the shock from the cold and also any depressing after-effect from the expansion of the gas in the intrapleural cavity.

Dr. George Mannheimer said there seemed to be some misconception as to the meaning and interpretation of the forms of pleural shock, pleural eclampsia, etc. He recalled a case where a pneumothorax was induced by an apparatus that had just been carried into the operating room from the cold outer air. The gas was cold. As soon as it entered the pleura the patient was seized by a violent spasm of the glottis. No healthy pleura would stand a traumatism of that kind. This was a normal pleural reflex. Dr. Mary Lapham last year reported similar accidents. As she put it, some of her patients could not catch their breath for a moment. That was entirely preventable by keeping the gas at the temperature of the ordinary operating room. The speaker said he had seen Brauer make a pneumothorax by his incision method and after opening the costal pleura he introduced a probe and tickled the inner layers. The patient at once went into slight syncope; that was, he turned pale, perspiration broke out upon the face, and pulse and respiration became rapid. After the withdrawal of the probe, the patient's condition returned to the normal. Brauer then cocainized the pleura, introduced the probe again, and nothing happened. This was another normal pleural reflex. It could be prevented by a previous hypodermic injection of morphine. The latter was known to diminish reflex excitability throughout the body. In contrast thereto, the more formidable accidents, like unconsciousness, convulsions, paralyses, and local spasms, were due to gas embolism. They could be avoided by careful observation of the manometer and of the patient and by careful technique. But in spite of all that, it might happen that the parietal pleura would be pierced where it was adherent to a tuberculous lung focus. If the needle happened to enter a pulmonary vein, the walls of which were held stiffly open by infiltrated tissue, the patient with the next breath actively sucked in air from the needle and tubing without the gas being turned on. This air might then be carried along through the larger collecting branches into one of the terminal pulmonary veins and enter the left heart and the systemic circulation. If the embolism was caught in a coronary artery, or in the artery supplying the medulla oblongata, instantaneous death resulted. Other symptoms would depend on the area the blood supply of which might be blocked by the embolus. An alarming accident was bound to occur in spite of all their precautions, for after all they were working in the dark. The operation itself was a splendid palliative measure in suitable cases. Dr. Kessel had admirably stated the indications. They should insist on safe and sane indications, because Italian and French physicians insisted on performing the operation in incipient cases. This was wrong, because one of the great questions, as yet unsolved, was this: "Did artificial pneumothorax really accomplish what was expected of it?" "Did the tuberculous areas really heal, and the lung re-expand after cessation of treatment?" There were cases on record in experimental animals as well as in human beings where the healthy portions of the collapsed lung had undergone fibrosis, that was, permanent alteration in structure and functions. This certainly was not desirable in early cases and, therefore, the operation should be confined to cases where all the well known methods of treatment had failed to arrest the progress of the disease.

Dr. Leo Kessell said that morphine had been used in all the cases, giving it ten minutes before the operation.

**The Frequency, Mechanism, Diagnosis, and Effects of Cardiac Displacements in Pulmonary Tuberculosis.**—Dr. Maurice Fishberg presented this paper. He called attention to the fact that cardiac displacements were much more frequent in pulmonary tuberculosis than was generally appreciated and that most clinicians overlooked them. In advanced cases of tuberculosis it was exceptional to find the heart in its normal place. Even pathologists overlooked it in making autopsies probably because post-mortem conditions did not show vividly the true location of the heart and its relations to the surrounding lungs, especially in the minor degrees of displacement. In the tuberculosis ward of the Montefiore Home he had found among 18 far advanced cases with lesions in the right side, or in which the lesion was more extensive in the right side, only one that showed no dislocation of the heart. Fourteen had dislocations to the right, and four to the left. Of 19 left-sided lesions, or in which the lesion on the left side was more extensive, 15 showed displacement to the left, one to the right, and one no displacement at all. Of 115 consecutive cases of tuberculosis in private practice in the early and second stages of the disease, he had found 50 per cent. of the hearts dislocated. Among 86 in the early stages of the disease, 36 per cent. showed cardiac displacements; of these 70 per cent. were dislocated to the left. Of 29 far advanced cases, 15 showed cardiac dislocations to the left, and 12 to the right. Most of these dislocated hearts were not pushed over from the affected to the healthy side, as was the case with pleural effusions, pneumothorax, etc., but were pulled toward the affected side. Shrinkage due to pulmonary fibrosis and collapse, cavitation, and retraction were effective as a *vis a fronto,* while vicariously, emphysematous lung on the opposite side encroaching with its bulk across the sternum, acted as a *vis a tergo,* to bring the heart out of its normal position. The heart was more easily moved toward the left than toward the right side, because of its strong attachment to the central tendon of the diaphragm as well as because of its oblique position in the chest. In cases with strong fibrous bands running from the right pleura to the pericardium, especially where there was cavitation in the right lung and the left lung was emphysematous, pushing the mediastinum to the right, all obstacles might be overcome and the heart dislocated to the right side. In extreme cases of this kind one might get dextrocardia, with the apex bent to the right of the sternum. The position of the diaphragm greatly influenced the location of the heart in tuberculosis, as had been shown by Pottenger. Elevation of the diaphragm elevated the heart, and if the elevation of one-half of that muscle greatly exceeded the height of the other half, it also pushed the heart to the opposite side, or attracted it to the same side in cases with strong pleuro pericardial adhesions which contracted and shrunk the affected lung. In many cases the heart was also rotated on its vertical or sagittal axis. Traction on the right side due to massive pleural adhesions, pulmonary fibrosis, etc., dragging the heart, when combined with an emphysematous lung in the left hemithorax, might give complete dextrocardia. In these cases there was not a complete rotation of the heart with swinging all the way around on its point of fixation at the great vessels, as was formerly supposed, but there was a complete shifting of the mediastinum to the right, bringing the heart into the right hemithorax, but retaining its natural position in the chest. Dextrocardia might also occur in cases of left sided pleurisy with effusion, pushing the heart to the right, where it was fixed by pleuropericardial adhesions and did not return to the left side after the disappearance of the fluid. They also got some cases of dextrocardia which showed that the direction of the long axis of the heart was from the left to the right, suggesting congenital dextrocardia without displacement of other organs. The cause of these dislocations was usually pushing of the heart to the right by a serous effusion in the left hemithorax and there it was fixed at the apex by pleuropericardial adhesions, so that when the fluid was absorbed or removed the base returned to its normal place, while the apex remained fixed at the right side sometimes beyond the mamillary line. Similarly in right sided lesions one sometimes met with cardiac displacements to the left, which were due to adhesive pleurisy of the left base which fixed the base in that position. The diagnosis of the heart dislocation in phthisis was at times difficult. The cardiac dullness at the side adjoining the affected lung merged with the dullness of the infiltrated lung or thickened pleura and

was difficult to separate. In some of these cases radiography was of no avail. In dextrocardia it should be borne in mind that when one found a cardiac impulse, it was usually the right ventricle and not the apex, because in these cases the latter was turned away from the chest wall; if one found two points of pulsation, the one to the left represented the apex and the one to the right the base or right ventricle.

**Observations Concerning the Liver in Acquired Syphilis.**—Dr. Harlow Brooks read this paper which was based on a post-mortem anatomical study of the liver in 50 consecutive cases of acquired syphilis and of a large series of clinical cases. He found the liver diseased in practically all cases. In 14 instances the liver was enlarged post mortem, in 18 atrophied, and in the remaining 18 cases it was normal in bulk. Typical syphilitic cirrhosis, that was, with deep bands of scar-like connective tissue was present in seven cases. A diffuse fibrosis, like that found in most alcoholics, was found in 12 instances, and this was the most frequent fibrous change in syphilitic livers. Gummata of varying size were found in seven cases, none being clinically diagnosable. The most frequent degenerative change naturally was a fatty degeneration found in 26 instances. Brown atrophy was found in seven cases and amyloid degeneration in an equal number. Acute yellow atrophy was apparently due to syphilis in one case. That the changes in the liver indicated individual and not general tendencies was suggested by the fact that they differed from the renal lesions in their general character in the same case in 34 instances and were analogous in 16. Liver symptoms rarely dominated; even in those cases where extensive liver lesions were present, the chief symptoms of the case were hepatic in but one instance. The most frequent symptom indicating liver involvement occurred in the secondary period and this was jaundice. It was generally supposed to be catarrhal in nature. They had showed it to be caused by true syphilitic inflammatory lesions, at least in most cases. Other symptoms were the general ones of hepatic fibrosis-ascites, pain, tumor, or atrophy. In most cases and excepting in gummata of large size the diagnosis of liver involvement was difficult to make in late lues. The lesions, except gumma, might be absolutely simulated by liver disease of other origin than from lues. The Wassermann reaction was almost always positive where the liver was extensively involved, and might be activated by a dose of salvarsan or mercury. Treatment was very promptly successful in the early stages. In the late stages, while it might cause the absorption of the gumma and the healing of syphilitic exudates, it would not usually be followed by reabsorption of the fibrous tissue; in some cases it might check progress in this direction, but in most cases the fibrosis or cirrhosis continued to advance even after vigorous and correct treatment. Treatment then to be entirely successful must be very early instituted.

**Radium and Röntgentherapy in Cancer.**—Dr. Isaac Levin read this paper. (See Vol. 84, p. 1064.)

---

SECTION ON OBSTETRICS AND GYNECOLOGY.

*Stated Meeting, Held October 28, 1913.*

Dr. Geo. Gray Ward, Jr., in the Chair.

The program was furnished by the staff of the Lying-in Hospital.

**A Review of the Craniotomies Recently Done at the Lying-In Hospital.**—Dr. Edward S. Gushee presented this report. He stated that from 1903 to 1913 there were delivered in the Outdoor and Indoor departments of the Lying-In Hospital 52,133 patients. In the Outdoor department there were 30,549 deliveries, among which there were 64 craniotomies, or about one-fifth of one per cent. In the hospital proper, during this period, there were 21,584 deliveries, among which were 258 craniotomies, or one per cent. of the cases delivered. This great discrepancy in the percentage of cases outside and inside the hospital was due to the fact that nearly all the cases outside the hospital were under the observation of the hospital staff, whereas in the hospital over one-half were emergencies and 125 had been unsuccessful attempts at delivery by outside physicians or midwives. This left 91 craniotomies which occurred directly under the hospital supervision, or two-fifths of one per cent. of the hospital cases. Of these 91 craniotomies, 21 were eclampsias, and seven were placenta previas with premature dead babies. In 29 cases craniotomy was done for the following causes: hydrocephalus, chondrodystrophia, impacted face, impacted brow, tuberculosis with dead fetus, diabetes melitus, endocarditis, and chronic nephritis. There were 23 borderline cases. In the hospital service, although there was an increase in the last five years of 4,000 deliveries, there was a decrease of two per cent. in the number of craniotomies from the previous five years; and in the tenements, although the increase of deliveries was only slight, there was a decrease of 20 per cent. in the craniotomies from that of the previous five years. In the hospital there were 37 deaths, which was 10 per cent. of the craniotomies, while in the outdoor service there was only one death. Of the 37 deaths in the house, six were due to complicating causes with one exception. Of 31 emergency cases 18 died of shock or hemorrhage, 10 of sepsis, and three of eclampsia. The high mortality rate inside the hospital was accounted for by the fact that the cases were sent in at all stages of delivery and had been tampered with on the outside. The low percentage of deaths in the outdoor service was due to the fact that the cases were under observation early enough so that they might be transferred to the hospital in time to permit of cesarean section. That the operation itself was not necessarily responsible for the death of the mother, but rather the state of shock to which she had been subjected or to some complicating condition was shown. All things considered, the maternal death rate in the hospital was not high and in the tenements it was practically *nil*.

**Set of Obstetrical Instruments Available for the General Practitioner.**—Dr. James W. Markoe said that every general practitioner should have such a set of instruments which could be used in any emergency, a simple and cheap set of instruments. What he presented covered almost every obstetric operation except that of cesarean section, pubiotomy, etc., which the general practitioner was not supposed to perform. The use of the instruments presented was well within the province of the general practitioner.

Dr. John O. Polak said that he was impressed with the simplicity of the instruments presented.

**A Specimen of Microcephalic Fetus at Nine Months.**—Dr. Robert Edward Pou exhibited this specimen in which the fontanels were practically closed up and there was contracture of the fingers of both hands.

**Esophagotreacheal Fistula, with Report of Two Cases.**—Dr. J. R. Losee reported these cases. He pointed out that esophagotracheal fistula was among the most common anomalies of the esophagus, for of 62 cases collected by McKenzie 43 had communication with the air passages. The first case occurred in an infant delivered normally at term. It was soon observed that the infant became asphyxiated at intervals of thirty minutes to an hour and that this condition was promptly relieved by the removal of a large quantity of yellow mucus from the pharynx. The baby nursed only for a few minutes, when it became asphyxiated and was relieved only when its head was lowered. Dr. Truesdell made a diagnosis of the exact condition owing to the fact that he had seen a similar case a year ago. A catheter could not be passed more than ten or twelve cm. from the alveolar border. With a No. 16 F. in this position a radiograph was taken which showed the level of the lower end of the sac. The patient gradually lost weight and on the eighth day a gastrostomy was done and feeding was carried on through a tube. It was later noted that milk placed in the stomach regurgitated into the mouth. Meconium was passed the first three or four days after birth, but after that there was very little stool. The child developed pulmonary symptoms and died of inanition and bronchopneumonia on the tenth day. At autopsy the esophagus was found to rise in its normal position and to terminate in a blind pouch three and one-half cm. lower down and two and one-half cm. from the bifurcation of the trachea. This pouch was one cm. in diameter, its walls were hypertrophied, its lumen distended, and there was no communication with the stomach. The stomach was normal in size and position and contained some food particles. There was a wound in the anterior wall one cm. in length and one and one-half cm. from the pylorus. The esophagus took its normal position from the cardiac end and terminated at the bifurcation of the trachea with which it formed an anastomosis. Its lumen was patent and communicated with the trachea and bronchi. The intestines were for the most part empty and there was a small diverticulum of the ileum about 10 cm. from the cecum. In these cases gastrostomy afforded little or no relief unless the cardiac end of the stomach was closed. In many of these conditions in which the esophagus ended in a blind pouch there was a fibrous cord extending from it to the cardiac end of the stomach; in others there were a few muscle fibers running from the termination of the sac downward on the posterior wall of the trachea. Then there was a variety in which there was absolutely no

traceable connection with the stomach. Cases had been reported where the rudimentary esophagus was from two and one-half to four cm. in length and again the fistulous communication with the trachea did not always take place at its bifurcation, but united with its posterior wall, one, two, or three cm. above it. About a year ago such a case was observed by them, and at autopsy the same conditions were found as had been here reported except that the lower portion of the esophagus communicated with the posterior wall of the trachea one cm. above its bifurcation. These infants all died, regardless of any treatment, from two to twelve days after birth. Such cases as these should be reported in order to keep ever before the eyes of the attending physician the occasional occurrence of these anomalies so that early diagnosis and definite prognosis might be made.

**Further Observations on Birth Fractures.**—Dr. Edward D. Truesdell read this paper, which was based on a series of fourteen cases of birth fracture occurring at the Lying-In Hospital. A series of eleven cases had already been reported in the Bulletin of the Lying-In Hospital, Volume VIII, No. 4. Since that time three additional cases had been added to the series. Of the entire series of fourteen, three had died, and the remainder had been under constant observation for eighteen months. Frequent *x*-ray examinations had been made, and where union with deformity had occurred this permitted inspection of the bone during the process of straightening, as nature moulded the bone into a form indistinguishable from that of the uninjured side. Ten of the fourteen fractures had taken place during version and breech extraction, three during simple breech abstraction, and one in a spontaneous vertex delivery in which difficulty was experienced in extracting the anterior arm from a narrowed pelvic outlet. The line of fracture in all cases but one was practically transverse in direction, a typical pipe-stem fracture, the site of the fracture being at or near the center of the shaft of the bone, apparently just below the insertion of the deltoid muscle. Deformity was absent at the first observation in some instances, but this, as a rule, appeared to some degree quite promptly, due to the necessary handling of the infant or to the infant's own activity. The more common type of deformity was an external angulation, in some cases of alarming degree, evidently aided by the deltoid pull. The second type observed was a lateral displacement, the fragments lying parallel, but at some distance from each other. Overriding was conspicuously absent. Wrist drop had been noticed accompanying every fracture. This evidence of nerve injury was not readily explained; as in each instance it had been present from the first it could not be due to either callus formation or pressure of extravasated blood. It might be that sufficient pressure had been brought to bear on the nerve, as this crossed the posterior surface of the bone to cause a traumatic paralysis before the bone itself gave away. An infant, dying within the first twenty-four hours of associated injuries, had afforded an opportunity for the examination of a fresh fracture by dissection. Extensive extravasation of blood was found in the deeper portion of the subcutaneous fat and beneath the deep fascia between the muscle planes. There was no evidence of violence to the brachial vessels or to the musculospiral nerve. There was an extensive tear in the periosteum anteriorly. The bleeding had taken place from the fractured bone ends, the torn periosteum and the surrounding lacerated muscle. The fracture was located just below the insertion of the deltoid. In the treatment of these cases a splint had been devised which had seemed more satisfactory than other appliances formerly tried. This splint was made of sheet lead, cut and folded in such a manner as, with the forearm flexed upon the arm, to press the upper fragment inward and the lower fragment outward, and at the same time to immobilize the fragments thus meeting the indications in either type of deformity. An extension of the splint across the infant's back fixed the whole arrangement to the body, immobilizing the entire arm. Later sheet aluminum was substituted for sheet lead, which, while less readily moulded and more resilient, was permeable to the *x*-rays, permitting examination through the dressing. From reading the radiographs alone it would seem that it did not matter how badly these cases were put up or whether they were put up at all. Apparently nature at this time of life is equal to dealing successfully with any degree of deformity in the upper extremity. However, the demand for relief from pain was present and with the application of the retention dressing, deformity, if present, should be overcome as far as possible. No case of non-union had occurred, although this might be possible in the presence of excessive deformity and absence of immobilization. Union had been firm in the majority of cases in three weeks. In one of the cases the wrist drop was still marked at the end of six weeks. The striking feature in the study of these fractures of the humerus had been the evidence of nature's ability to completely eradicate deformity apparently of an extent sure to be permanent when looked at during the first three months of life. It had proved that it was unnecessary, if not actually wrong, to refracture these bones before the second year of life. One case of Erb's paralysis complicated by fractured humerus had been followed with interest. The repair of the fracture itself took place as promptly as in the other cases, there being a slight degree of angular deformity. At the end of eleven months there was but slight improvement in the paralysis. It was noted here that nature had done less to eliminate the deformity in eleven months than in similar uncomplicated cases. Ten cases of fracture of the clavicle had been under treatment and followed, although not so closely as the cases of fracture of the humerus. Eight of these had occurred during version with breech extraction, one during a forceps delivery and one during a normal vertex delivery. The fracture was situated about the middle of the shaft of the bone, or at the juncture of the middle with the outer third. The displacement had been but slight in most cases, moderate in a few. The displacement had been of the sort observed in adults, the inner fragment being displaced upward, the outer downward and inward. These fractures had been treated simply with a Velpeau bandage in most cases; in others by means of a figure eight bandage across the back. Union had taken place promptly in all cases, usually with the formation of a visible callus mass. The final results had been good, both as regarded function and the restoration of the normal contour of the bone itself. Two cases of fracture of the femur had been under observation. The first occurred during version and breech extraction. This was treated by means of coaptation splints and bandages, no attempt at extension having been made. No *x*-ray examination was made at the time. The child was lost sight of for a year, at the end of which time she was observed to limp, the gait being of the waddling type seen in cases of dislocation of the hip. The injured leg was found to be fully one-half inch shorter than that of the other side. Radiographs showed no angulation laterally, although the upper portion of the shaft of the femur was thickened and the bone appeared more compact. On lateral inspection the bone showed well-marked anterior curvature, easily accounting for the shortening of the entire limb. The second case came under their care when one month of age. The labor had been an easy, spontaneous one, but the infant not beginning to breathe as promptly as was thought proper had been grasped by the legs and swung around in the air, fracturing its right femur. The injury had gone entirely untreated until the time of admission to the hospital. Union was firm, but the radiographs showed excessive angular deformity, both externally and anteriorly associated with well-marked over-riding. Callus was abundant and firm, and it seemed best to correct the external deformity only. This was done partly forcibly and partly by continuous traction. There was some improvement in the deformity under this treatment. Three cases, one treated not at all, and the others inefficiently, showed the tendency in this injury not only to excessive angular deformity, but to overriding that might result in permanent disability due to shortening of the femur, particularly if the child became rachitic later in childhood. These fractures of the femur in infants demanded traction for the relief of over-riding, as did corresponding fractures in adults. A long side splint could be employed arranged to provide extension by means of adhesive plaster straps applied from the site of the fracture to the ankle, and, if necessary, coaptation splints could be applied in addition about the thigh itself to counteract the tendency to angular deformity. This series of infantile fractures occurred during a period of one and one-half years in all the services of the hospital in a total of about 9,000 cases delivered.

Dr. Leon Theodore LeWald said that while it was not difficult with modern apparatus to make an instantaneous radiograph of an infant, yet to duplicate the results which Dr. Truesdell had obtained in his large number of cases showing the progress and final result in each case showed great patience and skill. It was of interest to all to note how union had occurred, even in cases showing considerable separation of the fragments. A good prognosis could therefore be given in this class of fractures, if reasonable care was taken in their treatment.

**Statistical Review of the Work of the Lying-In Hospital for the Past Five Years.**—Dr. Ross McPherson made this report. He stated that during the past five years

the Lying-In Hospital had taken care of 26,997 confinements and attended 27,326 births. During this time there had been 225 cases of placenta previa, making the frequency of this complication 0.8 per cent. of all cases. There were 204 cases of eclampsia or a frequency of 0.7 per cent. There were 33 deaths of mothers in eclampsia or 17.65 per cent. of all deaths in confinement. The total number of deaths of mothers was 302 or a mortality of 1.1 per cent. The total number of still births was 1,213 or 4.06 per cent. The total number of ectopic pregnancies was 58 or .21 per cent. The number of hydatidiform moles was 17 or 0.06 per cent. The total number of abortions was 1,310 or 4.9 per cent. The total number of twins was 314 or 1.19 per cent. The number of triplets was 10 or 0.04 per cent.

**Additional Experiences with the Dialyzation Method for the Serodiagnosis of Pregnancy.**—Dr. C. F. Jellinghaus and Dr. J. R. Losee presented this communication. They stated that the dialyzation method for the serodiagnosis of pregnancy was difficult, not because of any one detail but because of the very many details, a break in any one of which would spoil the test, no matter how perfect the rest of the technique had been carried out. For example, when a dialyzer was filled with non-pregnant serum and placenta, and the mixture was covered with a layer of toluol, if any small particle of placenta remained in the inside wall of the dialyzer without being covered with toluol, this particle would putrefy during the sixteen hours in the incubator, aminoacids would be formed, and thus the test would be spoiled. Another important step was the boiling of the ten c.c. of dialysate with 0.2 c.c. of a one per cent. solution of ninhydrin. This amount of ninhydrin did not react to very small quantities of amino-acids, such as were found in the dialysate of even non-pregnant cases, when the latter was boiled one minute. But even when boiled the amount of evaporation might differ, depending upon the flame, etc. It was important that evaporation should always be the same. In order to ascertain the amount of evaporation the fluid that was left after boiling one minute was measured. If this was not done one could readily fall into error. Given a non-pregnant serum to test, the control of placenta and inactivated serum came out negative, while the serum plus placenta came out positive. This result might lead one to condemn Abderhalden's claim unless the fluid remaining after boiling were measured; if measured, the control might show six c.c. left, while the dialysate of placenta and serum showed but five c.c. left after boiling one minute. In other words not Abderhalden, but the method of boiling was at fault.

Dr. Ralph G. Stillman said that this method was of the greatest importance, not so much as a method for the diagnosis of pregnancy as that it furnished good confirmatory evidence for Abderhalden's theory. Abderhalden's theory was apt to hold an important position in the development of theories of immunity and also in certain branches of physiology and the authors had done well to select a test the accuracy of whose findings were susceptible of positive demonstration. The application of this method would rapidly widen as time went on.

Dr. Jellinghaus said that in the dialyzation method for the serodiagnosis of pregnancy the work was difficult not because of any one detail but because the break in any one detail spoiled the general test. A point he wished to emphasize was the boiling for one minute; it was a great mistake in boiling the contents of the dialyzer too long.

Dr. J. R. Losee, in reply to Dr. Bailey's question in regard to the late toxemias of pregnancy, said that this reaction was more intense in eight of their cases of eclampsia, but it was not of great diagnostic value. He hoped that they would soon be able to graduate their results so that they might be of more value.

**Intravenous Injection of Weak Solutions of Magnesium in Puerperal Infection.**—Dr. James A. Harrar read this paper. He said that the use of magnesium sulphate intravenously for the treatment of puerperal infection was first proposed by Huggins in 1910. In 1911 Lobenstein reported a case of streptococcemia cured by the method. Dr. Harrar had now employed the injections in fifteen cases of severe puerperal infection, the bacteria having been demonstrated in the blood of six by repeated culture. A two per cent. solution of chemically pure magnesium sulphate was prepared with freshly distilled water. This was filtered and sterilized in half-liter flasks in an autoclave. This solution would not hemolyze human red blood cells suspended in salt solution, and from experience in over 100 injections would not cause any rigor or temperature reaction in the patient. A simplified salvarsan apparatus was used, and 300 or 400 c.c. of the solution was run into a vein of the arm. The injections might be repeated daily or at longer intervals. Thirteen injections were given in one case. The effect upon the bacteriemia might depend upon an agglutination of the streptococci or might depend merely upon the increased bulk of body fluid and alternation in surface tension of the body cells. Dr. Harrar reported the recovery of four women who had hemolytic streptococci in their blood out of the six with positive cultures. In the case of streptococcic toxemia but with negative blood cultures there was evident improvement after the injections. The value of the method for the present must depend more upon the clinical observations than on any theoretical consideration. In 46 cases of bacteriemia previous to 1910 in the hospital, the mortality was 93 per cent. In the six cases treated with magnesium sulphate since 1910 the mortality had been reduced to 38 per cent. The method was harmless if the injections were made very slowly and in the proportions described. The technique was simple and the materials cheap as compared with the use of antistreptococcic sera and the preparation of autogenous vaccines. The method appeared to be of more value early in the course of the blood infection before secondary localization had occurred. The cases were obviously few in number, but a record of four consecutive cures out of six cases of puerperal bacteriemia was a distinct improvement over any form of treatment in vogue at present.

Dr. Samuel J. Meltzer said that he had been especially interested in Dr. Harrar's report on the use of magnesium sulphate in the treatment of puerperal streptococcemia. The introduction of magnesium sulphate intravenously was not without danger, especially if the ratio of the infusion was not taken into consideration. Even a two per cent. solution might endanger the respiration if injected rapidly. There was reason to suspect from their recent laboratory experiments that fatty hearts might not stand well intravenous injections of magnesium sulphate even if carried out slowly. In the intraspinal injections very small quantities were used and the results were due to a local effect upon the central nervous system. On the other hand there was no remedy known for the ill effects of the intraspinal injections except artificial respiration, while against the toxic effects of the intravenous injection calcium intravenous injections were an excellent remedy. The antagonistic action of the two salts was marvelous and one who used intravenous injections of magnesium should familiarize himself with this action. Dr. Meltzer said he could not find any plausible explanation for the favorable action of the magnesium injection in puerperal fever. In half a dozen experiments on rabbits infected with virulent streptococci there was no evidence of a favorable action of magnesium injections. In clinical observations a dozen cases did not prove much. It should further be considered whether simply the water brought about a favorable result. A report had recently been published of a larger number of puerperal cases, 130 or more, which received merely injections of water with very satisfactory results. Perhaps the presence of the magnesium salts added to the diuretic effect of the water, and thus relieved the circulation of toxic products.

Dr. J. A. Harrar, in closing the discussion, said he believed it was always dangerous to draw definite conclusions from a few clinical observations. The exact value of the procedure was not yet proved. Magnesium sulphate did have one special action upon streptococci—it agglutinated them in saturated solution after an hour's incubation at 37° C. In culture growth it had no bactericidal action. It was necessary to prepare a homogeneous emulsion for agglutination tests, as streptococci grew in clumps and masses. The results immediately following the injections in some fulminating cases of streptococcic toxemia were impressive. One case of streptococcic bacteriemia recovered after two injections without secondary localization. Another case of bacteriemia recovered after six injections, also without development of secondary localization. The other two cases of bacteriemia were rather prolonged. One had an embolus in the pons with crossed paralysis and was in the hospital 160 days. The two patients that died were desperately ill on admission and went rapidly to a fatal termination without being helped by the magnesium injections. One developed panophthalmitis just before death. The other had an intense hematogenous jaundice.

---

## Philadelphia Neurological Society.

At a stated meeting held November 28 Dr. Charles S. Potts presented a specimen of "Tumor of the Right Temporosphenoidal Lobe in Which the Only Symptoms Were Mental, with Intense Papilledema." The patient was a blacksmith, 32 years old, who for a year had complained

of headache, with impairment of memory, and disorientation as to time and place. On one occasion he fell in an attack of what he designated "blind staggers" without convulsions or loss of consciousness. At a later period causeless vomiting took place. The gait was ataxic, as in cases of cerebellar disease, with a tendency in walking to fall toward the right. The right pupil was larger than the left and immobile, and there was marked papilledema of the corresponding optic disc. There was no history of syphilis and the Wassermann reaction was negative. Consciousness became clouded and a decompression operation was performed, but the patient failed to respond, and death ensued. On post-mortem examination a tumor was found infiltrating the right temporosphenoidal convolution, and histological investigation proved it to be a glioma.

Dr. William Drayton, Jr., presented "A Case of Spasmodic Torticollis." The patient was a postman, about 28 years old, with a history of gonorrhea, but none of syphilis, who, however, presented suggestive specific symptoms and also a positive Wassermann reaction. On a given occasion he had suddenly thrown his head back forcibly and he was immediately seized with pain in the nape of the neck, followed by the development of torticollis. Marked improvement followed treatment with salvarsan, mercury, and deep, vigorous massage of the involved area.

Dr. Francis X. Dercum demonstrated "A Case of Aphasie Motrice Pure (Déjerine) or Anarthrie (Marie)." The patient was a machinist, about 48 years old, who suddenly developed paralysis of the entire right side of the body, with loss of the power of speech. Ability to read and to write both from dictation and from copy, however, remained. A positive Wassermann reaction being obtained, salvarsan was introduced into a vein and active mercurial treatment was instituted. Improvement in the symptoms speedily took place and articulate and intelligent speech gradually returned.

Dr. Charles K. Mills presented a communication entitled "Impressions of the Recent International Congress, Especially with Reference to Neurology and Its Representatives."

Drs. F. X. Dercum, T. H. Weisenburg, and W. G. Spiller made remarks on the same subject.

## State Medical Licensing Boards.

### STATE BOARD EXAMINATION QUESTIONS

State Board of Medical Examiners for the State of Texas.

*Austin, June 24-26, 1913.*

ANATOMY.

1. Give the course and distribution of the trifacial nerve.
2. Name and give the origin of the arteries supplying the stomach, small intestines, large intestines.
3. Give the course and branches of distribution of the femoral artery.
4. Name the ligaments of the knee-joint.
5. Name the structures forming the larynx.
6. Give the formation of the brachial and lumbar plexuses and name main branches given off from each.
7. Enumerate the bones forming the orbit.
8. Give origin, insertion, nerve supply, and action of the pronator radii teres muscle.
9. Describe the diaphragm, its principal openings and nerve supply.
10. Give the characteristic points of cervical, dorsal, and lumbar vertebræ.

PHYSIOLOGY.

1. Give average normal temperature, rate of pulse and of respiration in (*a*) the infant, (*b*) the adult, (*c*) the aged.
2. Define protoplasm, and give the characteristic properties of living protoplasm.
3. Describe the heart sounds, and state to what they are due.
4. What digestive changes take place under the influence of saliva and of gastric juice.
5. State the origin and function of bile; give quantity secreted in twenty-four hours.
6. Describe the process by which digested food is absorbed.
7. Describe the physical properties of the blood, and name its constituents.
8. State origin of urea in the body; give average amount excreted in twenty-four hours.
9. Give function of (*a*) medulla oblongata, (*b*) the cerebellum.
10. Describe in detail how the placenta performs its function.

CHEMISTRY.

1. Complete the following equation: $NaCl + H_2SO_4 =$ ——— and name resultant compounds.
2. Differentiate ethyl alcohol from methyl alcohol, giving formula of each.
3. Name three extensively used carbon compounds which under certain conditions are dangerous to life.
4. State source of cyanogen gas and name two most important compounds.
5. Give a reliable test for nitrites.
6. (*a*) From what is the alkaloid muscarin derived; (*b*) give symptoms of poisoning; (*c*) fatal dose; and (*d*) physiological antidote.
7. How would you test water suspected of sewage contamination?
8. Describe a reliable method of determining the quantity of urea in a specimen of urine.
9. Describe a test for (*a*) albumin, (*b*) sugar, (*c*) pus, (*d*) blood, (*e*) indican, and (*f*) chyle.
10. Name chemical antidote for nitrate of silver or lunar caustic, and say how it acts.

PHYSICAL DIAGNOSIS.

1. State physical signs of pyloric stenosis.
2. Differentiate lobar from bronchopneumonia.
3. Give the physical signs of Raynaud's disease and describe the different grades.
4. State the principal diagnostic symptoms of scarlatina, diphtheria, variola, rubeola.
5. What is Cheyne-Stokes' respiration, Argyll-Robertson's pupil, Widal's test, Wassermann's reaction, Koplik's spots?
6. State briefly the principal diagnostic points of tetanus, exophthalmic goiter, chorea.
7. What are the plantar reflexes. What is the diagnostic value of the plantar reflexes.
8. In aortic and mitral insufficiency, where is the murmur heard most distinctly, and what is its direction of transmission.
9. Give differential diagnosis in ascites and cystic ovary.
10. Give differential diagnosis in cerebrospinal meningitis and acute anterior poliomyelitis.

### ANSWERS.

ANATOMY.

1. Trifacial nerve. *Superficial origin:* From the side of the pons Varolii. *Deep* (sensory root), from the medulla and upper part of cord; (motor root) from the floor of fourth ventricle and side of the aqueduct of Sylvius. *Exit:* The ophthalmic division, through the sphenoidal fissure; the superior maxillary division, through the foramen rotundum; the inferior maxillary division, through the foramen ovale. *Ophthalmic branch* distributed to conjunctiva, skin of upper eyelid, cornea, skin of forehead, and nose, lacrymal gland. *Superior maxillary,* to skin and conjunctiva of lower eyelid, nose, cheek, upper lip, upper teeth, and palate. *Inferior maxillary,* to external auditory meatus, side of head, mucous membrane of mouth, anterior two-thirds of tongue, lower teeth, and skin of lower part of face. Also to muscles as indicated below. It supplies sensation to all the parts mentioned above; but, in addition, inferior maxillary supplies motion to the muscles of mastication, the mylohyoid, and anterior belly of the digastric.

2. The *stomach* is supplied by the gastric (from celiac axis), pyloric (from the hepatic), right gastroepiploic (from the gastroduodenal), left gastroepiploic and vasa brevia (from the splenic). The *duodenum,* by the pyloric and pancreaticoduodenal (from the hepatic), the inferior pancreaticoduodenal (from the superior mesenteric). The *rest of the small intestine,* by branches of the superior mesenteric (from abdominal aorta). The *large intestine,* by the ileocolic, right colic, and middle colic (from the superior mesenteric); left colic, sigmoid, and superior hemorrhoidal (from inferior mesenteric). The *rectum,* by superior hemorrhoidal (from inferior mesenteric); middle hemorrhoidal (from internal iliac), and inferior hemorrhoidal (from internal pudic).

3. The femoral artery is the continuation of the external iliac, beginning behind Poupart's ligament, passing down the front and inner side of the thigh, and terminating at the opening in the adductor magnus, where it becomes the popliteal artery. It passes through Scarpa's

triangle. *Branches.* Superficial epigastric, superficial circumflex iliac, superficial external pudic, deep external pudic muscular, anastomotica magna, and profunda femoris (with branches, external circumflex, internal circumflex, and three perforating).

4. *The ligaments of the knee-joint* are: Capsular, anterior, posterior, internal lateral, two external lateral, external crucial, internal crucial, transverse, coronary, and two semilunar fibrocartilages.

5. *Structures forming the larynx:* Nine cartilages, viz., thyroid, cricoid, epiglottis, two arytenoids, two cornicula laryngis, and two cuneiform. The thyrohyoid membrane, cricothyroid membrane, thyroarytenoid ligaments, capsular ligaments, hyoepiglottic ligament, thyroepiglottic ligament; and, interiorly, the vocal cords.

6. The *brachial plexus* is formed by the union and subsequent division of the anterior divisions of the fifth, sixth, seventh, and eighth cervical and the first dorsal nerves. The union of the fifth and sixth makes the upper trunk; the seventh forms the middle trunk, and the eighth cervical and first dorsal make the lower trunk. Each of these trunks is divided into an anterior and a posterior branch. The anterior branches, from the upper and middle trunks, make the upper or outer cord of the plexus; the anterior branch of the lower trunk becomes the lower or inner cord; the three posterior branches unite to form the posterior or middle cord. The plexus lies between the Scalenus anticus and medius. The *branches* are: (1) Above the clavicle; communicating, muscular, posterior thoracic, and suprascapular. (2) *From outer cord:* External anterior thoracic, musculocutaneous, and outer head of median. (3) *From inner cord:* Internal anterior thoracic, lesser internal cutaneous, ulnar, and inner head of median. (4) *From posterior cord:* Subscapular, circumflex, and musculospiral.

The *lumbar plexus* is formed by the union of the anterior divisions of the first four lumbar nerves. The arrangement of the plexus is variable. The iliohypogastric and ilioinguinal come from the first lumbar nerve; the genitocrural comes from the first and second; the obturator comes from the second, third, and fourth; the external cutaneous comes from the second and third; the anterior crural comes from the second, third, and fourth; the accessory obturator, from the third and fourth.

7. The *bones which form the orbit* are: Sphenoid, ethmoid, superior maxillary, malar, lacrymal, frontal, and palate.

8. Pronator radii teres. Origin: Just above the internal condyle of the humerus and the common tendon, the fascia of the forearm and intermuscular septum, and from the inner side of the coronoid process of the ulna. *Insertion:* The middle of the outer surface of the shaft of the radius. *Nerve supply:* Median. *Action:* Rotates the radius upon the ulna; if the radius is fixed, it helps in flexing the forearm.

9. The *diaphragm* is a musculofibrous septum which divides the thoracic from the abdominal cavity; it is fan-shaped; the broad, elliptical portion is horizontal, and the crura are vertical. It is attached to the ensiform, to the internal surfaces of the lower six costal cartilages, to bodies and intervertebral substances of first, second, and third lumbar vertebræ. Its *openings* are: (1) The aortic, transmitting the aorta, vena azygos major, and the thoracic duct; (2) the esophageal, transmitting the esophagus, pneumogastric nerves, and some small esophageal arteries; (3) the opening for the vena cava, transmitting the inferior vena cava, and small branches of the right phrenic nerve; (4) the right crural, transmitting the right splanchnic nerves; (5) the left crural, transmitting the left splanchnic nerves and the vena azygos minor. *Nerve supply:* The phrenics, lower intercostals, and the phrenic plexus of the sympathetic.

10. The *cervical vertebræ* are distinguished by possessing a foramen in the transverse process. Further, they are smaller than those in the other regions; they have no facets for the ribs; the spinous processes are generally short and bifid; the spinal foramen is large and triangular; the superior articular process is directed upward and backward, and the inferior articular process is directed downward and forward.

The *thoracic vertebræ* have a heart-shaped body with a facet or demi-facet on each side for articulation with a rib; the laminæ are broad and deep; the spinous process is long and points downward; the transverse processes are long and articulate with the tubercle of a rib; the superior articular process is directed backward and slightly outward; the inferior articulate process is directed forward and slightly inward; the spinal foramen is smaller and circular.

The *dorsal vertebræ* have a large body, wider transversely, and with no facet or demi-facet; the laminæ are short and thick; the spinous process is horizontal; the transverse processes are "rudimentary"; the superior articular process is directed inward and slightly backward; the inferior articular process is directed outward and slightly forward; the spinal foramen is larger, and triangular.

PHYSIOLOGY.

1.

| | TEMPERATURE. | PULSE (per minute) | RESPIRATION (per minute) |
|---|---|---|---|
| Infant. | 98.6 to 99.6 F. | About 115 to 130 | About 40 |
| Adult.. | About 98.6 F. | About 70 to 80 | About 16 to 18 |
| Aged.. | About 99°F. | About 60 to 70 | About 18 |

2. *Protoplasm* is the material of which cells are made; it is living proteid material. The *characteristic properties of living protoplasm* are: Power of movement, of absorption, of ingestion, of excretion, of growth, of reproduction, and of response to suitable stimulation.

3. There are two normal heart sounds which follow in quick succession, and are succeeded by a pause. The first, or systolic, sound is dull and somewhat prolonged; the second, or diastolic, sound is sharper and shorter. The sounds may be expressed by the syllables *lubb—dup.*

The first sound is heard best at the apex beat in the fifth left intercostal space; the second sound is heard best over the second right costal cartilage.

The *causes* producing the *first* sound of the heart are not definitely ascertained; the following are supposed to be causatory factors: (1) the vibration and closure of the auriculo-ventricular valves, (2) the muscular sound produced by the contraction of the ventricles, and (3) the cardiac impulse against the chest wall.

The *second* sound is caused by the vibration due to the closure of the semilunar valves.

4. The *ptyalin* of the *saliva* converts cooked starch into maltose. The *gastric juice* converts proteids into proteoses and peptones and curdles milk.

5. *Bile* is *formed* in the liver cells. The *functions of bile* are: (1) to assist in the emulsification and saponification of fats; (2) to aid in the absorption of fats; (3) to stimulate the cells of the intestine to increased secretory activity, and so promote peristalsis, and at the same time tend to keep the feces moist; (4) to eliminate waste products of metabolism, such as lecithin and cholesterin; (5) it has a slight action in converting starch into sugar; (6) it neutralizes the acid chyme from the stomach, and thus inhibits peptic digestion; (7) it has a very feeble antiseptic action. The *quantity secreted* in twenty-four hours is said to vary between 500 c.c. and 1000 c.c.

6. The products of digestion find their way into the blood by two routes: (1) By the blood-vessels of the gastrointestinal tract, which unite to form the portal vein, and (2) by the lymph vessels of the small intestine, which converge to empty into the thoracic duct. The water, inorganic salts, proteids and sugar go by way of the portal vein to the ascending vena cava; and the fats go by way of the thoracic duct to the junction of the left subclavian and internal jugular veins.

The process by which absorption is accomplished is partly physical (osmosis and filtration), and is also due in part to selective action. To be absorbed by the blood-vessels or lacteals the substances must be in a fluid state, and the more dilute the solution the more rapid the absorption. The absorbed matter must be rapidly removed and fresh blood supplied to the capillaries.

7. The *physical properties of blood:* Fluid, somewhat viscid, red, specific gravity from 1055 to 1062, alkaline reaction, saltish taste, characteristic odor, variable temperature (average about 100° F.).

The *constituents of the blood* are:

1. Plasma.
2. Corpuscles { Colored. Colorless. Blood-plates.

8. "The greater part of the urea produced in the body is formed in the liver. The liver cells form the urea from two sources: (1) The larger amount, produced by the liver cells, is derived from the aminoacids which have been absorbed from the small intestine, and which are not required by the tissues; this constitutes the *exogenous urea.* (2) The smaller amount, produced by the liver cells, is derived from the ammonium carbonate, which is derived from the tissues; some is also produced by the action of the uricolytic enzyme upon uric acid; this constitutes the *endogenous urea.*" (Lyle's *Physiology.*) The

average amount of urea excreted in twenty-four hours is about 500 grains.

9. The *functions of the medulla oblongata:* (1) It is a conductor of nervous impulses or impressions from the cord to the cerebrum, from the brain to the spinal cord, also of coordinating impulses from the cerebellum to the cord; (2) it contains collections of gray matter which serve as special nerve centers for the following functions or actions; respiration, salivary secretion, mastication, sucking, deglutition, vomiting, voice, facial expression; it also contains the cardiac and vasomotor centers.

*Functions of the cerebellum:* Coordination of muscular movement, the maintenance of equilibrium.

10. "For the purposes of understanding its general function it is sufficient to recall that the placenta consists essentially of vascular chorionic papillæ from the fetus bathed in large blood-spaces in the decidual membrane of the mother. The fetal and the maternal blood do not come into actual contact; they are separated from each other by the walls of the fetal blood-vessels and the epithelial layers of the chorionic villi, but an active diffusion relation is set up between them. Nutritive material, proteid, fat, and carbohydrate and oxygen pass from the maternal to the fetal blood, and the waste products of fetal metabolism—carbon dioxide, nitrogenous wastes, etc.—pass from the fetal to the maternal blood. . . . We are far from having data that would justify us in supposing that the exchange between the two bloods is effected by the known physical processes of osmosis, diffusion, and filtration. . . . It is generally assumed that the chorionic villi play an active part in the process." (Howell's *Text-book of Physiology.*)

CHEMISTRY.

1. $NaCl + H_2SO_4 = NaHSO_4 + HCl$.

The resulting compounds are monosodic sulphate and hydrochloric acid.

2. Ethyl alcohol is $C_2H_5OH$; it boils at 173° F., and solidifies at —203° F. It attracts moisture from the air. On oxidation it gives ethyl aldehyde and acetic acid.

Methyl alcohol is $CH_3OH$; it boils at 151° F; it is not much affected by exposure to air, and when burned it gives less heat than ethyl alcohol does. On oxidation it gives methyl aldehyde and formic acid.

3. Ether, chloroform, and chloral.

4. Cyanogen gas may be obtained by heating the cyanide of silver or of mercury.

Two compounds: Potassium cyanide, and hydrocyanic acid.

5. *Test for nitrites:* (1) A solution of potassium permanganate is promptly decolorized by nitrites. (2) On addition of dilute sulphuric acid, a yellow gas ($N_2O_3$) is given off.

6. *Muscarine* is derived from some poisonous mushrooms, also from putrefying fish. *Symptoms of poisoning:* Increased secretion of saliva and tears, vomiting, diarrhea, contraction of pupils, slow pulse, cold perspiration, diminished respiration, and death. The *physiological antidote* is atropine. The fatal dose is small, probably 1/10 of a grain might cause death.

7. Water suspected of sewage contamination can be tested by being boiled with a solution of potassium permanganate of known strength. One liter of water should not decolorize ten milligrams of pure potassium permanganate when acidified with five cubic centimeters of sulphuric acid, and boiled for ten minutes.

8. A comparatively easy test for *urea* is that of Fowler, based upon the loss of the specific gravity of the urine after the decomposition of the urea of hypochlorite. "To apply this method the specific gravity of the urine is carefully determined, as well as that of the liquor sodæ chlorinatæ (Squibb's). One volume of the urine is then mixed with exactly seven volumes of the liquor sodæ chlorinatæ, and after the first violence of the reaction has subsided, the mixture is shaken from time to time during an hour, when the decomposition is complete; the specific gravity of the mixture is then determined. As the reaction begins instantaneously when the urine and reagent are mixed, the specific gravity of the mixture must be calculated by adding together once the specific gravity of the urine and seven times the specific gravity of the liquor sodæ chlorinatæ, and dividing the sum by eight. From the quotient so obtained the specific gravity of the mixture after decomposition is subtracted: every degree of loss in specific gravity indicates 0.7791 gram of urea in 100 c.c. of urine. The specific gravity determinations must all be made at the same temperature; and that of the mixture only when the evolution of gas has ceased entirely."—(Witthaus' *Manual of Chemistry.*)

9. *Test for albumin:* "The urine must be perfectly clear. If not so, it is to be filtered, and, if this does not render it transparent, it is to be treated with a few drops of magnesia mixture, and again filtered.

"The reaction is then observed. If it be acid, the urine is simply heated to near the boiling point. If the urine be neutral or alkaline, it is rendered *faintly* acid by the addition of dilute acetic acid, and heated. If albumin be present, a coagulum is formed, varying in quantity from a faint cloudiness to entire solidification, according to the quantity of albumin present. The coagulum is not redissolved upon the addition of nitric acid."

*Test for sugar:* First remove any albumin that may be present, then "render the liquid strongly alkaline by addition of sodium carbonate. Divide about 6 c.c. of the alkaline liquid in two test-tubes. To one test-tube add a very minute quantity of powdered subnitrate of bismuth, to the other as much powdered litharge. Boil the contents of both tubes. The presence of glucose is indicated by a dark or black color of the bismuth powder, the litharge retaining its natural color."

*Chemical test for blood in the urine:* To the urine add a solution of potassium hydroxide to distinct alkaline reaction; heat nearly to boiling (do not boil). A red precipitate is produced.

*For pus in the urine:* Acidify the urine with acetic acid, then filter it, and treat the filter with a few drops of freshly prepared tincture of guaiacum; a deep blue color denotes the presence of pus.

*Test for indican in the urine:* The urine is mixed with one-fifth its volume of 20 per cent. solution of lead acetate and filtered. The filtrate is mixed with an equal volume of fuming hydrochloric acid containing 3:1000 of ferric chloride, a few drops of chloroform are added, and the mixture strongly shaken one to two minutes. With normal urine the chloroform remains colorless, or almost so; but if an excess of indoxyl compounds be present the chloroform is colored blue, and the depth of the color is a rough indication of the degree of the excess. (From Witthaus' *Essentials of Chemistry.*)

In *chyluria,* the urine contains granular corpuscles like leucocytes and finely divided fat globules. The urine may be milky in color and contain filariæ.

10. The chemical antidote for nitrate of silver is sodium chloride.

It acts by forming the insoluble silver chloride:

$$AgNO_3 + NaCl = AgCl + NaNO_3.$$

PHYSICAL DIAGNOSIS.

1. *Physical signs of pyloric stenosis:* The stomach is dilated, and the outline shows the distention; palpation shows a tumor at the pylorus and also extended gastric peristalsis; succussion sounds may be elicited; a tympanitic note may be elicited on percussion if the stomach is empty, and this note extends to or below the umbilicus.

2.

| LOBAR PNEUMONIA. | BRONCHOPNEUMONIA. |
|---|---|
| Generally a primary disease. | Generally secondary (to bronchitis or an infectious disease). |
| Age has little influence. | Generally found in very young or very old. |
| Sudden onset. | Gradual onset. |
| Fever is high and regular. | Fever is not so high, and is irregular. |
| Ends by crisis between sixth and tenth day. | Ends by lysis, at no particular date. |
| Generally only one lung affected. | Generally both lungs affected. |
| The physical signs are distinct, and there is a large area of consolidation. | Physical signs indistinct, and the evidences of consolidation are indefinite. |
| Sputum is rusty. | Sputum is rather streaked with blood. |

3. *Raynaud's disease.* "The onset is sudden. Two or three fingers of both hands are usually involved. At first, or in a mild form, there is coldness, numbness, and waxy pallor of the fingers. They feel as if dead, the skin appears shrunken and there is slight anesthesia. This condition disappears, but returns again, and may become almost constant. All the fingers may be affected, more rarely the toes, tip of the nose, and the ears. This mild form (*digiti mortui,* dead fingers, local syncope) is due to a slight exposure to cold. In the more severe form the fingers are blue and swollen. There are burning sensations and much pain, without anesthesia. Gangrene follows this "local asphyxia." In the gangrenous stage the tips of the fingers become the seat of small blisters, which fill with bloody serum and then dry up. Beneath the scab

thus formed a shallow ulceration begins, which soon heals and leaves a scar. Occasionally hematuria may be present. The condition of *digiti mortui* may last a few days or weeks, perhaps months. The gangrenous stage usually continues for about three weeks." (Butler's *Diagnostics of Internal Medicine.*)

4. *Scarlatina:* Period of incubation, from a few hours to seven days. Stage of invasion, twenty-four hours. Character of eruption, a scarlet punctate rash, beginning on neck and chest, then covering face and body; desquamation is scaly or in flakes. The eruption is bright red on a red background, punctiform, and is uniform; the temperature is high, the pulse quick; the tongue is of the "strawberry" type; the lymphatics in the neck may be swollen, and there is sore throat; Koplik's spots are absent.

In *diphtheria* the onset is gradual; the temperature rises to about 101° to 103° F.; the tonsils are not much enlarged; there is an exudate of a thick grayish membrane which is very adherent, is removed only with difficulty, and leaves a bleeding surface; this membrane soon reforms, and may be found on the fauces and pharynx as well as on the tonsil; in the exudate the Klebs-Loeffler bacilli may be found.

*Variola:* The eruption usually appears first on the forehead and wrists, and on the third or fourth day; it is first macular, then papular, then vesicular, and finally pustular; it does not appear in successive crops; the spots are multilocular, and do not collapse on being punctured; the papule is hard and shotty, and does not disappear on stretching the skin.

*Rubeola:* Period of incubation ten to twelve days. Stage of invasion, four days. Character of eruption, small, dark red papules with crescentic borders, beginning on face and rapidly spreading over the entire body; desquamation is branny. As compared with scarlatina, the eruption is darker, less uniform, more shotty; the temperature is lower, pulse slower, the tongue is not of the "strawberry" type; coryza, coughing, and sneezing may be present; Koplik's spots are present.

5. In *Cheyne-Stokes respiration* the respirations gradually increase in volume and rapidity until they reach a climax, when they gradually subside, and finally cease for from ten to forty seconds, when the same cycle begins again.

*Argyll-Robertson pupil* is a condition in which the pupil accommodates for distance but not for light.

*Widal test* is an agglutination test more or less relied on in the diagnosis of typhoid fever. It depends upon the fact that serum from the blood of a typhoid patient if mixed with a recent culture of typhoid bacilli will cause the latter to lose their motility and gather in clumps.

*Wassermann's reaction* is said to be diagnostic of syphilis. A watery extract of syphilitic fetal liver is used as the antigen to fix the syphilitic immune body in the serum.

*Koplik's spots* are small red spots with a bluish central area, found on the buccal mucous membrane, in measles.

6. *Tetanus:* Dysphagia; pain and stiffness in the muscles of the lower jaw and neck; tonic spasms of the muscles of the back, legs, and abdomen; the jaws become rigid and locked; opisthotonus and risus sardonicus are present.

*Exophthalmic goiter:* Protrusion of the eyeball, goiter, tachycardia, and muscular tremor.

*Chorea:* Irregular, spasmodic, fibrillary movements of groups of muscles, made worse by excitement; irregular and tumultuous heart action.

7. *"The plantar reflex* is produced by tickling or scratching the soles of the feet. This causes usually, when carefully done, a slight flexion of the toes. In many cases there is, however, no response. In irritable persons and children there is a sudden dorsal flexion of the foot, and often a contraction of the inner hamstring muscles. In pathological conditions involving the pyramidal tracts of the cord or even the motor centers and tracts in the brain there is a dorsal extension of the great toe. This is called the sign of Babinski. A similar phenomenon, *i.e.*, extensor response of the big toe, is produced by firmly compressing the muscles of the calf (Gordon reflex), and by causing the patient to draw his leg up sharply flexing the thigh on the abdomen and the leg on the thigh (Oppenheimer flex). With this dorsal flexion of the toe there is usually a slight plantar flexion of the other toes." (Dana's *Nervous Diseases*).

8. In *mitral insufficiency* there is a blowing murmur, heard best near the apex, systolic, transmitted to left axilla and under left scapula; it modifies or replaces the first sound. In *aortic insufficiency* the murmur is soft and blowing, is heard best over the aortic area, is diastolic, is transmitted down the sternum, and modifies or replaces the second sound.

9.

| ASCITES. | OVARIAN CYST. |
|---|---|
| 1. Previous history of visceral disease. | 1. No such history. |
| 2. Enlargement comparatively sudden. | 2. Gradual. |
| 3. Face puffy; color waxy; early anemia. | 3. Facies ovariana. Anemia absent, or later. |
| 4. Patient on back, enlargement symmetrical; flat in front. | 4. Asymmetrical until tumor is quite large; prominent in front. |
| 5. Sitting up, abdomen bulges below. | 5. No appreciable change. |
| 6. Navel prominent and thinned. | 6. Navel usually unchanged. |
| 7. Fluctuation decidedly clear, diffuse throughout abdomen, but avoids highest parts in all positions, and always has a hydrostatic level. | 7. Less clear; limited to cyst; not modified by change of position. No hydrostatic level. |
| 8. Intestines float on top of fluid; hence percussion gives clear tympanitic note over the highest parts of abdominal cavity, and dullness in lowest parts for all positions, *i.e.* areas of resonance and dullness change with position. | 8. No change in areas of dullness and resonance with change of position. Dullness over cyst. Clear resonant note in all parts beyond cyst limits, *i.e.* in flanks and toward the diaphragm. |
| 9. Vaginal touch detects fluctuation, bulging into vagina. | 9. Vaginal fluctuation less clear or absent. |
| 10. Uterus in prolapsed location, but position unchanged. Size and mobility unchanged. | 10. Uterus displaced forward or backward, or laterally by pressure of cyst. |
| 11. Hydragogues and diurectics temporarily remove the fluid. | 11. Medicines have no effect. |
| 12. Fluid light straw color and thin. Coagulates spontaneously. | 12. Fluid light or dark and of varying consistency; albuminous, but does not coagulate spontaneously; may contain colloid matter. |

(Dudley's *Gynecology.*)

10. *Symptoms of acute anterior poliomyelitis:* Some fever, chills, and convulsions may precede the paralysis, or the onset may be sudden; certain groups of muscles (generally in the extremities) are paralyzed; hemiplegia is rare; the reflexes are generally lost; the paralysis is irregular in its distribution, and tends to ameliorate, but the recovery is only partial; the affected muscles waste, and the limb is cold and livid.

*Cerebrospinal meningitis* begins with a chill, vomiting or convulsions, and rise of temperature. The pulse is full and strong. There are hypersensitiveness to light, sound, and touch and excruciating pain in the head, back, and limbs. A petechial rash appears and sometimes herpes is present. Leukocytosis is the rule. The urine is scanty, high colored, and may be albuminous. If the meninges of the brain are most involved, delirium, stupor, semiconsciousness, paralysis of the ocular muscles, disturbed vision, and deafness may be present; if those of the cord are most affected, there will be opisthotonos, hyperesthesia, paresthesia, rigidity and tremor of the extremities, localized spasms, and convulsions. *Kernig's Sign*—The patient should be propped up in bed in the sitting posture; then, on attempting to extend the leg on the thigh, there is contraction of the flexors, which prevents the full straightening of the leg. In the recumbent position the leg can be extended. *The diagnosis* is made by the history, mode of onset, character of the eruption, absence of physical signs, symptoms, and lumbar puncture. (*Pocket Cyclopedia.*)

*(To be continued.)*

**The Tuberculous Soil in Gonorrheal Arthritis.**—L. Tomassi refers to the teaching of Pellizzari that gonorrheal arthritis occurs only in individuals predisposed to or suffering from tuberculosis. He cites his own clinical experience in support of this view. In fact, gonorrheal arthritis may serve as the first indication of the tuberculous habitus, and demands a dual treatment, that of the local joint condition and that of the constitutional disease caused by the bacillus of Koch. —*La Riforma Medica.*

### THE DIAGNOSIS AND TREATMENT OF LUMBOSACRAL PELVIC PAIN.*

By FREDERICK P. HENRY, M.D.,

PHILADELPHIA, PA.

PROFESSOR OF THE PRINCIPLES AND PRACTICE OF MEDICINE, WOMAN'S MEDICAL COLLEGE OF PENNSYLVANIA.

I ACCEPTED the invitation to take part in this symposium rather impulsively. When I received it I was suffering from a sharp attack of lumbago, and it seemed to me that so far as the diagnosis and symptomatology of that particular form of lumbosacral pain were concerned I had nothing to learn and a great deal to say. After my letter of acceptance had been dispatched I noticed, what had previously escaped my attention, that the treatment of the various forms of lumbosacral pelvic pain were to be discussed and began to reflect upon the inefficacy of treatment in my own case. I then regretted that I had been so impulsive.

The commonest form of lumbar pain is undoubtedly lumbago. Very few escape it. Some have had it in their youth and outlived it, or think they have; some have outlived their youth and have not yet suffered from it, but they are a negligible quantity, and even they are not immune. In most cases the patient, if he is well advanced in years, will tell you that he has suffered from it at intervals of months, or even years, in early manhood, in middle life, and in old age. It is not, in my experience, a disease of adolescence. I have had such a personal interest in lumbago that I have looked up the word in the lexicon. It is not a classical word. It was first employed by a certain Sextus Pompeius Festus, a grammarian, who wrote in the early part of the eighth century, A. D. The fact that the first person who used the word was a grammarian suggests the idea that he suffered from the affection himself and coined the word which, ever since his time, has been applied to it. He defines lumbago as a "vitium et debilitas lumborum." The word vitium, literally vice, naturally suggests the idea of syphilis, but there is no causal association between lumbago and syphilis. I do not mean to imply that they are mutually exclusive, but, in my experience, the syphilitic are no more liable to lumbago than the non-syphilitic. The sufferer from lumbago has sometimes almost wished that the affection were syphilitic, for in that case he would have specific remedies at his command.

The diagnosis of lumbago is, in most cases, a very simple matter. Its sudden onset in the midst of health, usually after some trivial exertion, such as lifting a child from the ground, putting up a dumbbell, or even leaning over to tie one's shoestrings, with the simultaneous conversion of a yielding and flexible into a rigid and painful spine—these symptoms, together with the seat of the pain in the lumbosacral region are usually all sufficient. Tenderness on deep pressure over the sacroiliac symphysis may usually be elicited, and it is sometimes limited to one side or, if bilateral, is greater on one side than the other. The general health is usually not in the least impaired. Now, while the disease seems generally to be caused by some kind of muscular exertion, it will be found on careful inquiry or equally careful introspection that there were some slight premonitions of the attack beforehand. In other words, the disease was already present when the movement called into play the muscles and tendinous structures involved in it. Or one might almost suppose that the disease was present, but unperceived until the muscular movement had, in some unknown way, opened up paths of sensory conduction which had been previously blocked.

I have said that the diagnosis of lumbago is easy, but I have known it to be confounded with abdominal aneurysm. I was once *particeps criminis* in such a diagnostic blunder. At the time, it was in the seventies, I was one of Dr. Strawbridge's assistants at his eye infirmary. The patient was a young man with syphilitic retinitis. I can recall him to mind most distinctly; I even remember his name. His eye-ground presented such a beautiful picture that we encouraged him to come almost daily to the infirmary and we gazed at his retina while he complained bitterly of his backache. We attributed it to syphilis and were right in so doing. One Sunday morning Dr. Strawbridge received word that this patient, in whom he took a great interest, had suddenly died, and he summoned me and his other assistant, Dr. Nancrede, to go with him to the man's house to make an autopsy. It did not take us long to find the cause of the lumbago. The abdominal cavity was filled with clots from a huge ruptured aneurysm which had deeply eroded the bodies of two or three of the lower lumbar vertebræ. I have never made the same mistake again, but I came very near it a few years ago at the Philadelphia Hospital. I was going through the ward with my resident, who had just completed his term of service in the neurological department and knew the name of every reflex, tendinous or cutaneous, and seemed especially interested in the subject of spasticity. He called my attention to a patient who was seated in the chair at the foot of his bed in a doubled-up attitude and told me that he ought to be transferred to one of the so-called nervous wards. On asking his reasons for this opinion I was told that the man had all sorts of exaggerated reflexes and a well-marked spastic paralysis. The backache which was the man's chief complaint seemed to be a minor consideration. I did not examine the patient, but consented to my resident's request that one of the chiefs

*Read at the meeting of the College of Physicians of Philadelphia on December 3, 1913.

of the neurological department should be consulted. This chanced to be Dr. Burr, who found the patient in bed, and on turning down the bedclothes to examine him detected an abdominal aneurysm as big as a football. I never saw any one more mortified than my resident, who was kind enough to acquit me of all responsibility in this case of mistaken diagnosis on the ground that I had never examined the patient. Shortly afterward the aneurysm ruptured and the cause of the spastic paralysis and of the lumbago was plainly manifest. The lumbar vertebræ were eroded to such an extent as to lay bare the anterolateral columns of the cord.

Obstinate "lumbago" in the female should invariably lead to a uterine examination. I recall the case of a woman of fifty who had suffered for more than a year with severe "lumbago." She also had rheumatoid arthritis, which association had misled others into the belief that the "lumbago" was rheumatic. On uterine examination I found the cervix occluded by a fibroid polypus almost as large as a walnut. It was removed with immediate and permanent relief of the lumbago. The case is reported in detail in Vol. VIII, Path. Soc. Trans. Phila.

The so-called typhoid spine, to which attention was first called by Gibney of New York, is an affection of which I have had little experience, and that fact is sufficient to make me doubt its connection with typhoid fever. I say so because I have been in continuous service in large hospitals in this city since 1874, when I was elected visiting physician to the Episcopal Hospital, and during this period of about forty years have, as a matter of course, treated many hundreds of cases of typhoid fever. It seems to me, therefore, that if there existed any regular association between spondyilitis, or perispondylitis, or any other affection of the spine, and typhoid fever, it would not have escaped my attention.

The spondylose rhizomélique of Marie is neither more nor less than osteoarthritis of the intervertebral articulations, but its symptoms are so definite and so peculiar as to justify its separate place in nosology. Leaving lumbar pain out of the question, although that is the only symptom which warrants me in referring to the disease, it is recognized when well advanced by spinal rigidity, cervical kyphosis, and the regular involvement of the shoulder and hip joints.

There is one variety of lumbar pain of which the diagnosis is of the utmost importance. I refer to the pain, which may be intense, that is dependent upon metastatic carcinoma of the vertebræ. When the primary seat of carcinoma is the breast the metastasis referred to may occur and the question of operation under such circumstances is one which, I believe, would be decided by most surgeons in the negative. The diagnosis of this condition, *i.e.* the decision whether metastasis has or has not, occurred, can only be the result of the most careful investigation of the sensation and motion and reflexes of the parts inervated by the painful spinal area. I recently had under my care a patient, seen also by Drs Gibbon and Spiller, whose case illustrated the vital importance of this differential diagnosis.

To return to the subject of lumbago. This word, like indigestion and jaundice and every other symptomatic term, is liable to abuse. In speaking of indigestion I once remarked (see preface of the seventh edition of Flint's "Practice of Medicine") that it is a "serviceable cloak for ignorance but had been worn threadbare and is about to be discarded." The same is not altogether true of lumbago. It is undoubtedly a serviceable cloak for ignorance, but it is not likely to be discarded because it is the name of a genuine disease for which, as yet, we have none that is better. So far as I know, Gowers has done more to elucidate the obscure subject of lumbago than anyone else (*British Med. Jour.*, January 16, 1904). There are some diseases which we look at as through a glass darkly, while of others which we now see face to face it may be said that there was a time when we were actually looking away from them. Notable instances of these latter are malaria, yellow fever, infantile paralysis, and many others. Of lumbago it can be said that while we may not yet be seeing it face to face, we are, at least, not looking at it back to back, *i.e.* away from it.

Gowers regards lumbago as an inflammation of the fibrous tissue of the muscles and not of the sensory nerve endings, basing this opinion chiefly upon the fact that the disease, beginning apparently in the substance of the muscles, extends to the tendinous structures. By such extension sciatica, *i.e.* inflammation of the sheath of the sciatic nerve, often arises. Gowers considers this extension of lumbago to the tendinous structures, and especially to the sheath of the sciatic nerve, as of fundamental importance in determining its nature, for if, says he, "a morbid process, by extension, presents itself as manifest inflammation, it must be originally inflammatory in nature." He acknowledges that the inflammation is of peculiar type, inasmuch as it does not produce induration or suppuration and coins the word *fibrositis* to designate it.

The same process, fibrositis, which gives rise to lumbago, is found, as a matter of course, in other muscles than those of the lumbosacral region. We are all familiar with it in the trapezius muscle, but, according to Gowers, it reaches its maximum severity in the muscles of the arm. He gives a vivid description of this brachial myalgia or muscular fibrositis, as he prefers to call it, and speaks of it as "a terrible malady." The slightest attempt at motion, either active or passive, causes the most intense pain and the joints of the shoulder, elbow, and wrist may be fixed as though by adhesions. When this affection is the result of an injury and involves the deltoid, fracture of the upper part of the humerus may be suspected. I have seen such cases before the days of the *x*-ray, when the patient had to be etherized in order to make a diagnosis. We are all familiar with a variety of sore throat in which, with no inflammation of the mucous membrane of the pharynx, there are pain and aching greatly exacerbated by deglutition. We call it rheumatic and treat it accordingly and often with brilliant success. It is due to the muscular fibrositis of Gowers as are also pleurodynia and other varieties of myalgia. Nevertheless we cannot take strict issue with those who apply to them the more popular term of neuritis for they all tend to involve the nerve sheaths and, in some cases, eventually the tissues of the nerve itself, with consecutive muscular weakness and atrophy and disturbance, or loss, of sensation. The fact appears to be that the distinction between the muscular fibrositis of Gowers and muscular neuritis is largely hypothetical, a distinction with little difference. The sensory structures of muscle, the so-called "*muscle spindles*," convey the sensations characteristic of lumbago, but their anatomical structure is such as to cause them

to be regarded as belonging to the fibrous tissue of muscle, "to that which sheathes and connects the muscular fibers, rather than to the latter." If, therefore, as Gowers maintains, lumbago is an affection of the interstitial muscular fibrous tissue, a muscular fibrositis, and the sensory nerve endings, the "muscle spindles" are part and parcel of that tissue, it stands to reason that myalgia and muscular neuritis are inseparable.

I have consumed most of the time at my disposal, but I have wasted none of it in discussing the fallacy that lumbago is the result of dislocation of the sacroiliac joint. I have no doubt that luxation or subluxation of this joint may occur and that it may be reduced by surgical manipulation. I have not, however, been speaking of a surgical affection. I have been discussing a variety of inflammation which is common to the muscles of the lumbosacral region and to those of the shoulder, the arm, the throat, the thorax, in a word, to the entire muscular system, and the fact of this general participation in the process is sufficient refutation of the fallacy to which I have alluded.

I will confine my remarks on treatment to the therapeutics of lumbago. The question whether lumbago is a manifestation of gout or articular rheumatism is an interesting one from the pathological standpoint, but has little bearing on therapeutics for, in most cases, the salicyl compounds and their congeners, as well as colchicum, are of not much avail. Gowers holds that the anamnesis will reveal that the victims of lumbago, while they may never have had a well defined attack of gout or rheumatism, are, in most cases, the descendants of gouty or rheumatic ancestors. They are suffering vicariously for the excesses of their progenitors, or, to employ the figure of the prophet Ezekiel: "The fathers have eaten sour grapes and the children's teeth are set on edge." Nevertheless, the salicyl compounds should be given a trial, especially at the beginning of the attack, and they will sometimes abort it. I have seen excellent results from a single large dose of quinine, meaning thereby from ten to twenty grains, administered at the onset of the affection. The late Dr. Fagge taught that lumbago is generally due to a hyperacid state of the urine and there are many who still hold this opinion. The indication, from this therapeutic standpoint, is to make the urine alkaline as rapidly as possible with sodium or potassium bicarbonate or potassium citrate which seems to be the favorite drug for this purpose employed by the English practitioners. Half-drachm or drachm doses of Rochelle salts are, I think, preferable. They may be administered every hour or two until the urine is alkaline and the bowels freely moved.

Lumbago affords one of the best examples of the importance of early treatment. The attempt to "walk it off," at its commencement, may succeed if the exercise is accompanied with free perspiration, but, in my experience, those who suffer from lumbago do not perspire readily. A Turkish bath in the early stage is safer and more effective than exercise. When the affection is established, rest is imperative. Then, also, local treatment consisting of dry cups, deep massage, and the faradic current should be instituted, and if the salicyl compounds and their numerous succedanea have failed, successful resort may be had to iodine. This drug I have found most efficient in its combination with a vegetable protein. I have had no experience with acupuncture which is strongly recommended by Osler.

## DISORDERS IN CHILDREN BY IMITATION AND INDUCTION.

By AUGUST STRAUCH, M.D.,

CHICAGO, ILL.

### PHYSIO-PSYCHOLOGY.

The study of children reveals their extraordinary endowment of imitation; this constitutes a factor of fundamental importance, playing a paramount rôle in the evolution of psychic life in both the normal as well as the pathological direction. The origin of the properties that form human character, such as good or bad habits or emotions, to a great extent may be traced back to the age when instinctive imitation—unconscious of purpose and without judgment—represents almost the only psychic faculty; we may observe everywhere how this faculty influences and directs other impulses with irresistible force. Imitative-reactive actions are recognizable at a very early stage of life. They represent then, as a matter of course, a form of imitation that is of the lowest grade and purely without consciousness of purpose; only later does the understanding of the movements prompted by imitation supervene.

Even the nursling may give evidence of a neuropsychic contagion—however primitive—as, for instance, if one of several infants begins to cry, soon several others, often all, will follow suit. Or a single nursling likewise may begin to cry from hearing others cry. This kind of an imitative act occurs without volition—that is, without the apparent influence of a conscious will—giving rather the impression of a direct reflex action of a subcortical order.

The capacity of imitating, becoming later more complex and associative through the interpolation of consciousness, volition and purpose increases for some time during infancy and childhood, but it later decreases with growing intelligence and, finally it is the less, the higher the degree of the psychical development, the personal originality, the intellect acting as a kind of brake, inhibiting the imitation reflex, and coordinating it with the opposite motives of self-affirmation and independence. Yet, in no sphere of our life, esthetic, moral, practical, or theoretical, are we really free from the inclination to imitate; in fact, it is one of the fundamental and most important social instincts; and we can see in social life at all times the masses following and aping their leaders, and regulating their actions according to a standard with which they regularly compare themselves. Society is a fabric or structure, built up by the instinct of imitation in all its various forms, as custom, fashion, education, prejudices, heroic acts and crime or reflex-imitation, etc.; the spirit of the times in the political and business life is led by this basic force. Imitation and psychic contagion, however we may term the factors, that we shall consider here, have their cause in the "suggestion" or reflex receptibility which is a cardinal attribute of psychic life. They may operate upon one or several individuals, upon many or whole masses of persons; they may spread like an epidemic among mankind, leaving some unaffected, others only slightly influenced, and the rest deeply and forcibly stirred up.

The pronounced inclination of the young child to mimicry is evidently an indication that the stimuli which affect the eye or ear, pass through the nervous system without much cortical inhibition, thus calling forth immediately a reaction similar to that which the child sees or hears in another. Con-

sidering the coercive character of these imitative impulses we shall find them especially strong, and aggravated to a pathological degree, in the echokinesis (echomimie) and echolalia of some feeble-minded children, in dementia præcox, in psychic infantilism, etc., where there is lack of the physiological cortical control. Some idiotic children, indeed, are hardly able to refrain from immediately reproducing gestures or other movements that they see others executing, or from repeating automatically words or syllables just heard. Especially do the mongoloids yield to their uninhibited imitativeness. These conditions of reflex automatism, which represent to a certain degree a transitory evolutionary stage of the normal child, thus persist in these individuals. When existing in the presence of less marked psychic defects, they may be misinterpreted as naughtiness.

We shall encounter hysteria repeatedly in the course of our dissertation with its great suggestibility, not only the abnormally increased effectiveness of extraneous suggestion, but also of autosuggestion, as a prolific soil for the development of neuropathic or psychopathic imitation states.

### SPEECH DISTURBANCES.

The development of speech is founded upon the faculty of imitation. The earlier speech activities are only concerned with a purely instinctive form of imitation, in which the acts of another are repeated as accurately as possible, without necessarily any conscious purpose to imitate. The sensations of the vocal sounds made by others seem to discharge immediately in articulatory reactions in an almost reflex manner, more or less closely resembling the stimulus. The sensory (acoustic) impression represents thus the stimulus that evokes the speech movement, as though by reflex action. It is plain that an especially important period of development in the acquisition of correct speech is that in which the baby has learned to be attentive, *i.e.* not only to hear, but to listen. Here the phenomenon of imitation has become akin to a still higher reflex. Therefore this is the time that the foundation is laid for the various speech disturbances and anomalies by imitation; here the occasion presents itself for the child to acquire apparent or potential defects of speech. Wherever the linguistic exemplar is defective and shows anomalies, we must not wonder at finding later similar defects in the speech of the child. The purer and more beautiful the vocal sounds, the better the enunciation of the child's exemplar, the more may we be assured of the acquisition of perfect speech by the normal child.

We cannot dwell at length on the subject of speech disturbances and will only make a few general remarks. In lisping, the influence of imitation is generally admitted to be very important. Gutzmann, for instance, observed that this speech defect in one instance was brought into a family by a lisping maid, so that all of the five children copied the same disorder. Rhinolalia (nasal speech), as the result of imitation, has also been repeatedly observed among brothers and sisters of persons afflicted with cleft palate. In stuttering, while the imitation of the identical defect in relatives or playmates is certainly a factor not to be undervalued, it must be admitted that its influence may not be very great, unless there is predisposition or heredity. Psychical infection is blamed in 9 to 13 per cent. of the cases. Gutzmann reports a case of stuttering through imitation from only a short exposure.

A gentleman voluntarily commented on the fact that after talking for a time with a friend who stutters he himself temporarily exhibits the same fault, unless he consciously avoids it. Similar conditions exist in dyslalia.

### IMPORTANCE OF THE MILIEU.

Imitative or induced disturbances of the nervous system and psychic sphere and vegetative functions of children are very important; they are manifold and protean, and known even to the laity, who recognize the special proneness of the children to imitation; the latter are very susceptible to impressions and suggestions by the immaturity, instability and undevelopment of the character. The mighty, almost magic, force of example upon them may be seen at every turn in both the pathological as well as the psychological direction. Children indeed also participate very vividly in the excitement, emotions, and passions of the adult, though in a way of their own. Historical examples of this last mentioned fact are presented on the grandest imaginable scale by well known occurrences in the middle ages, when phantastic religious and political passions gained such a control over the world of childhood that here they manifested themselves in stronger expressions and with more intensity than even in adults; this will be dwelt upon later.

In the presence of these peculiarities of the psychic life, and on account of its tendency to discharge physical reactions upon impressions, the environment or milieu of the child is possessed of momentous import. Therefore no wonder that a disease, observed in another person, may give rise to similar morbid symptoms in children. In this field of imitativeness and suggestion it may not always be possible to draw the exact boundaries or lines of demarcation between healthy and morbid conditions. If one person by yawning induces others to yawn, or if a man made a wager that he could make a whole class, even including the teacher, yawn and won, as in an authentic case, we will hardly declare this pathological. The contagiousness of laughter, cheerfulness, worry, panic, or inspired terror and the imitative choking of pertussis are also well known. Horace ("Ars Poetica") gives expression to these facts in saying: "As laughter creates laughter, as tears cause tears to flow, so do miens understand each other." Montaigne justly says in regard to nervous contagion: "The aspect of pain in others gives me pain, too, and a person that coughs uninterruptedly irritates also my own lungs and throat." The phrase of Mme. de Sevigné, written in a letter to her daughter, who coughed, became celebrated: "J'ai mal à vôtre poitrine." So when confronting a person afflicted with tic convulsif or stereotypia, we may feel forced, at least temporarily, to similar muscular contractions to find relief from the peculiar sensation of tension due to the influence of the exemplar.

It is therefore not strange that a neuropathic, hysterical person should render others permanently in contact with him likewise nervous in the course of time, and that the latter should acquire and appropriate, as it were, certain nervous habits. The danger of forming and developing such nervous disorders by imitation and autosuggestion is, of course, with the child, greater than with the adult.

### PSYCHIC EPIDEMICS.

Such disturbances may afflict not only the individual child but even large groups of children;

indeed the history of medicine abounds in examples of such psychic epidemics of an imitative origin. As a vibration struck brings into sympathetic vibration similar instruments, so a psychogenic epidemic in its spread draws with irresistible power the individuals of similar susceptibility into its magic circle. This simile, though being no explanation, is very descriptive. The manifestations of passion or sensation in one individual call out similar psychic effects in the other persons. These processes seem to us so natural that they appear independent of volition. While the single individual may still be able to successfully set criticism and inhibitory motives, conscious or subconscious, against an extraneous alien psychic influence, yet these barriers may be broken or swept away by the impetus and weight of passions if they seize upon large masses; psychic phenomena may then be manifested by persons not at all of a neurotic predisposition and individually even healthy. An idea, even morbid or irrational, strengthened in its impression by passion, seems to constitute the contagion in the adult more than is the case in childhood, where oftener a more or less automatic imitation or inducement takes place by simply sensory impressions without other more complex psychic agencies, although both factors, of course, may sometimes co-operate, when it might be difficult to say to what extent the "contagion idea" is the motor power in an epidemic.

### HISTORICAL EXAMPLES.

The famous avalanche-like commotion of the children's migrations and crusades of medieval times are to be explained on the ground of psychic contagion, as are likewise the epidemic dancing manias in which also children participated. The persons afflicted by the dancing mania moved through cities in frantic ecstasy, performing phantastic dances, in which they reached a state of unreasoning rapture, and finally fell to the ground exhausted by the physical and psychical overstrain and overexertion. As is known, this frenzy, principally arising from religious fervor, seized whole masses and spread gradually over the whole of Germany and the northern countries, as the hosts affected with the disease wandered from place to place, and from country to country. Thus this prodigious epidemic raged in certain regions for two centuries. A number of chroniclers relate how children participated in this phenomenon among the adults, nay, how they even performed their mad dances independently by themselves. For instance, in the year 1237 more than 100 children were suddenly seized by this dismal disturbance and passed, dancing and jumping, from Erfurt to Arnstadt, where they fell to the ground from exhaustion. Not a few of them, restrained by their parents or brought back home, are said to have either died soon or remained afflicted with tremor throughout their lives. (Hecker.) It is assumed that the peculiar psychic predisposition was due to the marked effect of misery from the famines, frequent wars, and terrorizing plagues that swept over Europe, in the presence of religious excitement and dire superstition, so characteristic of medieval times; this deep commotion of the nations may also explain the extent and long duration of these extraordinary conditions. In 1458, when the great chorea (St. Vitus' dance) was prevalent in Germany, more than 100 children started against the will of their parents from Hall in Suebia for Mont St. Michael in Normandy. The mania for martyrdom, in the beginning of the fourth century, ranks in the same category of induced epidemics, according to Hecker's view. Here also children in great numbers participated; likewise in the performances of flaggellantism, in which children carried out the rôles of flaggelants, partly in association with adults, partly also entirely by themselves or alone, as for instance, at Speier.

The materio-realistic spirit of our times, *der Zeitgeist*, is much less conducive to the origin of psychical aberrations of religious color in such vast epidemic and prodigious forms; not only on account of education and enlightenment, where these exist, but possibly more because the terrific anxieties of the middle ages, are fortunately wanting with their profound, intense, and almost continuous strain. On the other hand, modern era is apt to create in the child a predisposition to various functional nervous disorders, producing nervousness and abnormal mental states, due to the overburdening in our schools and the artificial manner of life.

### CRIMES.

The development and propagation of pathological phenomena from one to another, to several or many persons, and finally to whole masses, is not limited to psychoneurotic diseases in the stricter sense, but manifests itself also in suicide and crimes, especially in mob crimes, and in false testimonies through influencing the memory pictures even of otherwise truthful children.

Moreau in his work, "Insanity in Childhood," reports the occurrence in France during the last decade of several epidemics of hysteria, and cases of bloodshed, murder, and suicide, in which imitative impulses were responsible to a great extent. Sensational suicides of famous persons were repeatedly followed by multiple suicides, even semi-epidemics from the numbers, and suicides of several members of a family in distress are well known. This interesting subject is dealt with at length by Scipio Sighele in his work on collective psychology, and by Morselli. Epidemics of crimes are recorded by Despine. Juvenile crimes are to be referred to imitation and inducement, where a corrupt environment is the most conspicuous if not the only factor, with an effect more or less strong, according to the degree that moral resistance is lacking.

### RELIGIOUS PSYCHIC EPIDEMICS OF OUR TIMES.

The literature of our times abounds with reports of psychic epidemics, whose character may bring them often near or within that morbid entity which we term hysteria. I must content myself with specifying a few occurrences that will characterize the various aspects and symptoms of these phenomena. There occurred in Sweden as late as 1842 the so-called preaching disease among children, mostly girls, as a manifestation of some underlying religious agitation. It derived its name from the fact that the children affected felt themselves irresistibly forced to preach; at the time they showed various morbid nervous symptoms. Many suffering from headaches and convulsions drifted into a stage of the disease in which they had religious visions and hallucinations, and began to preach. These convulsions consisted in involuntary shaking movements of the arms and the body; they would begin whenever the patient was reminded of anything "sinful," as, for instance, by hearing tabooed words (satan, sin, oath, etc.), or whenever some one contradicted them. In a more advanced stage these "convulsionaires" would tumble backward

and fall into a sleeplike state, in which they saw certain religious apparitions, clapped their hands, and laughed. Strange to say, children exclusively, especially girls, never adults, were affected by this singular disturbance. During the attacks the afflicted was overpowered by an impulse to preach, as mentioned before. This preaching mania seemed to result from a mere irresistible impulse rather than from an intention to edify, for they made exhortations, preached penance, conversion, and reform, even when entirely alone, as, for instance, in forest or field. Meanwhile their domestic work and other duties were performed in their ordinary course, and their family life suffered no disturbance. (Spengler). The phenomenon pervaded whole provinces like an epidemic and affected children in great numbers. Similar epidemics of preaching mania were observed also elsewhere, as, for instance, in Baden in 1852 and 1853, where likewise children exclusively were affected. Increased nervous irritability, religious reveric and fanaticism, belief in sorcery, and imitation were blamed. (Rees). Also, in 1861 the revivals in the orphan asylum of Elberfeld were characterized (Veltusen) by religious ecstasy, pathological affects and emotions, caused by sermons and accompanied by hysterical convulsions, representing conditions essentially identical with those observed in the revivals of the English Methodists in North America (especially among the negroes) and Ireland.

An analysis of occurrences of this character seems to establish a common psychic agitation of whatsoever purport, as the first phase, for instance, a religious commotion, stirred up by sermons and ceremonies. Then, whenever under its influence one person or the other manifests conspicuous physical reactions, another phase takes place; a spreading of these physical symptoms, sweeping like an epidemic among the others, through the agency of contagion or nervous sympathy (suggestion) by sensory (visual) impression. In the "hystero-demonopathie" epidemic in Morzine in Savoy (Kuhn) a great number of girls, 12 or 13 years of age, were seized with convulsions, illusions, hallucinations, and fits of violence.

### SCHOOL EPIDEMICS.

However psychogenic institution epidemics appear at the present time, rather than the great psychic epidemics of the Middle Ages, which were principally of religious origin. The number of these imitation epidemics in educational or other institutions, especially in girls' boarding schools, hospitals, and prisons, is perhaps greater than is generally believed, since it is to the interest of these institutions to prevent such occurrences from becoming generally known.

The cases in the hospital at Haarlem are much quoted, where an epileptic by his seizures through imitation transmitted his convulsions to all the other patients. Van Swieten observed spasms, from which small children suffered, mimicked by all those who were unfortunate enough to be witnesses. Palmer, in 1892, observed in a girls' school in Biberach (Germany) about 13 children from 11 to 13 years of age who all manifested sleeplike conditions. Rembold, in 1893, reported a psychic epidemic in a girls' school at Stuttgart. After a girl had fainted 25 cases of nervous disturbances occurred. Fifteen girls were affected with tremor and screaming, 10 with unconsciousness and sleeplike states. Hirt, in 1893, reported that 20 girls among 38 between 5 and 12 years of age were taken ill with hysterical spasms and disturbances of the sensorium near Lignitz, in Germany, in the village school of Gross Tinz. Szegoe observed at Budapest in 1895 a singular cough prevalent in a girls' institution (chorea laryngis). Bokay witnessed a very unique and spectacular psychic epidemic in a girls' school near Budapest. Fifteen girls between 9 and 15 years of age who were affected imitated the cries of various animals by peculiar expiratory sounds. A pupil, who had previously suffered from catarrhal cough, suddenly had an expiration that resembled the sneezing of a horse. Soon after two other pupils produced also peculiar expirations, which, however, sounded more like barking. Still other girls reproduced the hissing of geese, the shrieking of parrots, the neighing of horses; the majority, however, imitated the barking of dogs. Whenever one girl started the rest apparently had to join in, thereby creating a confusion of noises as if "from the animals of a menagerie." Bokay excluded intentional imitation. Von Holwede described an epidemic of light attacks of spasms with sleeplike states in a high school in Braunschweig.

Singultus is not infrequently marked by its epidemic spread. In 1897, when I was still in Vienna as a medical student, there occurred an epidemic of hysterical singultus in a class of a girls' school in the second district, in which 28 girls among 35 were victims, so that the class had to be closed. Dr. Berdach, who has reported this imitation epidemic, in addition to this made a similar observation in another school in which 20 girls among 30 were affected. Schuette describes the occurrence of "trembling disease" in a girls' school at Meissen.

Unique and very interesting were the observations made by Schoedel of a peculiar disturbance of handwriting that spread among the children of a class in a public school in Chemnitz, 21 of the 35 pupils being affected. During the first days of the disturbance the children, girls and boys, would write well at the beginning of their lessons, but gradually in the course of the hour the handwriting became more and more tremulous. During the following days the characters and figures were tremulous even at the beginning of the lessons and became finally very grotesque and unreadable. This peculiar ataxia of the hand and arm movements appeared only in writing, not in other kinds of work. There were no signs of nervousness, exhaustion, or excitement present. Shortly before the outbreak of this epidemic the daily newspapers published repeatedly articles about a school epidemic of trembling disease in Meissen, where 134 children, mostly girls, were unable to hold any light object, such as a penholder, during the attack. It was proved that the first patient in Chemnitz had heard of this epidemic. In the opinion of Schoedel, this example and the suggestion of the teacher in expressing to his pupils the hope that they might be spared the trembling disease of Meissen served actually as the provoking agent of the epidemic in Chemnitz. In this case the children imitated the peculiar disturbance of the writing of their near neighbors. Schoedel is averse to classifying this or similar psychic epidemics among the manifestations of hysteria, as some authors do, because it dealt mostly with well nourished, healthy, not neuropathic children, of average education and healthy parentage and for other very plausible reasons. He applies to these phenomena the unprejudiced term,

"induction or imitation diseases." Certainly such conclusions must be approved for a great number of psychic epidemics, though in others hysteria, as the underlying factor, is too conspicuous to be denied. "It is the physiological underdevelopment of the child's psychic organ with its great tendency to imitate, and the impressionability of mind and the vivid imagination that render such epidemics possible. A real disease is not necessarily a factor, as idiosyncrasies and aberrations may be imitated. Girls are possessed of these childish characteristics in a more pronounced degree than boys and enjoy more leniency, and this factor is apt to aggravate such evils."

When children, in aping instinctively the bad habits of adults, suddenly exhibit the morbid manifestations seen in others, we must not always necessarily presume an abnormally increased imitative tendency a morbid impressionability; in such cases the milieu may be sufficiently influential to affect the child. Finally, we must remember that a certain theatrical talent exists in the normal child, which becomes evident in their play; undoubtedly this may aid at least in inducing the children to copy and ape others, including abnormal persons, especially if their desire is directed towards "playing a rôle." The more conspicuous the feature of the example the more will the instinct of mimicry in the child be aroused.

I shall only cursorily point to the occurrence of enuresis nocturna in previously healthy children as due to psychic contagion by unconscious imitation of classmates and friends who are afflicted with this disturbance. Also the so-called school headaches, which as a rule are of neurasthenic nature, seem to be due to hysterical imitation and suggestion in a number of cases. Thiemich, as school physician, relates the experience that in some classes one-third or more of the pupils, mostly girls, between 10 and 14 years of age, upon inquiry asserted that they suffered from headaches, while in other classes with the same number of pupils of the same age only sporadic cases were present. A suggestive therapy with tinctura amara was generally followed by speedy and permanent cure, though the neurasthenic forms remained uninfluenced. Thus we see that these epidemics present an endless variety of symptoms, and we realize that the phenomena are too many to enumerate. One feature is common to all of them: psychic contagion in a limited circle of children who spend many hours together and are more or less embraced by the same bonds, as in schools or other institutions.

### SPORADIC CASES.

Though the individual physician may not often meet imitation or inducement diseases in epidemic extent, he will have the greater opportunity to deal with sporadic, isolated, individual cases with a great variety of induced disorders. We have seen imitativeness within this limit call forth hysterical symptoms, especially of irritative, though also of paralytic character, in predisposed individuals. In truth, this very factor in hysteria of childhood prevails over all other provocative circumstances (imitation hysteria). Very marked and typical is Oppenheim's observation: A boy acquired through psychic contagion a hysterical contracture of both feet with well developed varoequinus position after seeing a bilateral pes equinovarus in a child. Its true nature remained unrecognized for a long time. Finally the posture of the feet became normal again after a single treatment. Hutinel narrates the experience of Dufour with a young hysteric who visited a hospital at Berck (Tuberculosis Sanatorium) and became coxalgic. I saw a Jewish girl, 10 years old, who began to limp after having seen limping patients while spending a short time at Hot Springs (Ark.) with her mother. The limping occurred in attacks during the following months. In walking, the left leg was swung forward, but the right leg could not be brought farther forward than the side of the standing left leg. Cure followed suggestive treatment. In another case, a boy, suffering from paresis of the legs after diphtheria, was mimicked by his ten-year-old brother, who after having been bedridden on account of bronchitis, suffered from abasia and astasia.

Terrien in his sanatorium gave a report of a patient who was moribund from uremia. To demonstrate the rhythm of Cheyne-Stokes breathing he himself reproduced this symptom. A few hours later he was hurriedly called to a young female who had listened to that demonstration; she presented this very symptom of Cheyne-Stokes and declared she must die from uremia.

As well known, the acute or slow psychic trauma, the deep impression made upon the mind of a person witnessing epileptic or hysterical seizures may provoke in him similar convulsions; or even more severe manifestations, exaggerations may be produced. The Romans therefore forbade such persons participation in public meetings and gave this disease also the name "morbus comitialis." Similarly chorea minor has been transmitted by psychic contagion. We see occasionally, though not often, in one and the same family where a child is affected with the infectious (rheumatic) form, that a second child manifests very similar symptoms by imitation, the mimetic form (chorea nervosa, imitatoria). Also small epidemics of imitatory chorea minor were observed in whole classes of girls' institutions, where imitation of the hysterical symptoms is especially conspicuous. Of course this imitatory form can not be regarded as genuine chorea minor, though the clinical resemblance may be great in some instances. Such hysterical cases may represent merely choreiform movements or movements without a certain rule and difficult to define; generally they are characterized by more monotonous, regular or rhythmic and coordinate muscular movements, *e.g.*, trampling; they have been described by Charcot and others under the term "chorée rhythmique." They may cease suddenly and be of short duration. Wichmann describes an epidemic of so-called St. Vitus' dance at Wildbad in 1885 and 1886, in which hysteria however was conspicuous mostly in the form of chorea rhythmica; but a few cases represented the clinical features of chorea minor and major. The same holds true of the epidemic chorea in Necker (Brichteau) and others collected from the literature by Wichmann.

We shall not wonder that motor disturbances belonging to organic diseases as, for instance, the tremor of paralysis agitans, etc., have also been mimicked by children with more or less exactness of the crude clinical picture, particularly if it was a family member who suffered from this tremor of organic cause.

I lately saw a school girl, age 10 years, who had had trembling of both hands for a few days; this also was apparent in the handwriting. This disorder was most probably due to imitation of the

tremor of her 53-year-old father, inasmuch as shortly before she had manifested attacks of a peculiar nervous dyspnea, imitating similar attacks of her hysterical mother.

Peritz made the following observation: Electrical treatment in a girl 14 years old provoked hysterical chorea, wherein the choreic movements were an imitation of the muscular contractions by the electrical current. The case bore a great semblance to chorea electrica (Henoch's).

The various vague and painful sensations of children due to psychogenic reproductions of and the vivid sympathy for other people's pains, which sensations resemble organic disease of the inner organs, are a matter of more common experience. These deal mostly with headaches or pains in the abdomen or chest. In a greater number of cases than is usually believed visceral and sensory disturbances, in hysterical girls especially, can be traced to the suggestive influences of their parents' example, most often the mothers', who complain day by day of their ailments and pains, imaginary or real, in the presence of their children. A child may complain of backache, or headache, or of pains in the chest or abdomen or the limbs, merely because the mother suffers from such pains. The father has a "bladder or kidney trouble" and consequently the imaginative child begins to complain of similar pains. I have seen a number of such cases.

These pains prove very amenable to suggestive treatment, especially if the parents cease complaining of their own ills.

In one case a girl suffered from attacks of pains in the back and the heart, and of palpitations, so that she could not attend the school for a while; the only explanation was the imitation of her nervous mother, who much disturbed the family life by her complaints of similar and other symptoms.

It is evident that in so far as the parents and other family members are the most important examples and the principal part in the child's milieu, their conduct is of paramount import. If the former manifest more or less pronounced nervous disorders they awake in the child corresponding ideas, and guide its imagination in a certain pathological direction; such parents also by the anomalies of their character in the sphere of emotion or volition are bound to be of immense educational detriment to their children. In such families we see the effect of a hereditary neuropathic constitution aggravated by the injurious and permanent influence of a morbid environment. Evil examples not only deprave good morals and manners, but also may directly and seriously interfere with the normal health of the nervous system, and good examples are better than the best sermons or lectures; nothing is more conducive to healthy nerves than a family life with happiness, love, and an atmosphere of tranquillity.

The unconscious or subconscious remembrance—the latent idea—of the act of vomiting observed in another person, from whatever cause, may make the child vomit. In one instance a child suffered for a long time from nervous vomiting that began from the moment she saw another child regurgitate medicine given him. In another case a girl vomited daily for months after she saw her mother seasick when coming to this country. Prompt results were obtained by suggestive treatment. In a family with children already convalescent from pertussis, when one of them began to vomit again, all the others started vomiting anew and continued for 8 to 10 days. Likewise the inability for keeping down certain food may sometimes be traced to unconscious mimicry or verbal suggestion. Cramer cites in his article on hysteria (Bruns' Handbuch, etc., page 87) a very illustrative case in an eight-year-old girl of hysterical constipation, brought about by the fact that the parents, who suffered from constipation, frequently discussed their ailment in the presence of the child and showed themselves solicitous about the child's digestion. Immediate cure followed the removal from the home but recurrence of the symptom occurred upon return home. Instances of pseudoappendicitis induced by suggestion and imitativeness have been seen. The following observation is quite typical (Cramer): A girl complained of the symptom complex of appendicitis after several of her friends had been operated upon for this disease. A well-known surgeon diagnosed hysterical pseudo-appendicitis. As Czerny observes somewhat sarcastically in regard to such and similar cases: "repeatedly have such cases been successfully operated upon where success could have been obtained by a simpler therapy." It is unnecessary to say that such a diagnosis requires great caution and care. Also upon closer inquiry we may in a number of instances of nervous cough, or dyspnea, or asthmatic conditions successfully trace the affection to unconscious mimicry. Pertussis as an imitation neurosis of hysterical nature occurs only among older children and seems to be very rare. The absence of nocturnal paroxysms facilitates the recognition of its true nature. Haase reported an epidemic in an orphan asylum, that was at first considered to be pertussis, but later it was recognized as hysterical laryngismus.

Deficient training and psychic contagion play an important etiological or provocative rôle in the acquisition of the various forms of tic convulsif, especially in the young, although an inherited neurotic constitution has to be present to furnish a basic cause or predisposition. Not infrequently is the twitching voluntary, at least in the beginning, for instance, in thoughtless imitation of some ticing child or teacher. In some instances one might be at a loss to decide whether to consider these muscular contractions merely as a bad habit, acquired by imitation, or as a real disease. Thus, making grimaces, belching, etc., are observed especially among boys. Intentional mimicry is strong in the child's nature and bad habits are quickly contracted. Should a child be tainted with nervous weakness in addition, he is apt to tic at the slenderest pretext; in such a case it would be dire misfortune to encounter, or still more to be associated with a subject of tic. A novel gesture on the part of anyone catches the child's attention and he forthwith attempts its reproduction, finding therein a source of complacent satisfaction. On the morrow the movement is repeated, and again, till it oversteps the bonds of habit and enters the realm of tic (Meige and Feindel). In Tissier's case imitation was not only the pathogenic but also the therapeutic agent. An ocular tic was acquired by an eight-year-old girl from her mother and transmitted by imitation to a second child; the cure of this second child was followed by a cure of the others through imitation.

One meets not infrequently in schools and eye clinics children, mostly pale, delicate, nervous ones, who from seeing myopic classmates with eyeglasses, partly by imitation, partly by the desire for eyeglasses mimic myopia and bring objects near to the eye, nearer than necessary, in cases where an in-

significant anomaly of refraction is present. Plane glasses will satisfy the child and induce it to hold the object at a proper distance. On the other hand, strabismus (convergens), which the laity is so ready to explain by imitation of a squint-eyed person, has nothing to do with it. Its cause lies in the relationship of accommodation and convergence.

In regard to the vita sexualis of childhood we can not ignore the imitative tendency especially, because it lacks the many inhibitory considerations and concepts of the adult life; it might play for this reason a great rôle in conjunction with the desire to reproduce certain sensations that have once been learned. We must remember that actions, outwardly of sexual appearance, may not always be the result of a premature sexual impulse, but merely the product of imitation, as, for instance, if a boy runs after a girl and both flirt, merely to do what they see others do, or, perhaps, with the added desire to be taken for grown-up persons. Or, when children, playing father and mother, denude themselves, they may do so from a dawning sexuality, but undoubtedly in some instances from mere imitation. A great number of sexual crimes and abnormalities observed among groups and certain circles of persons in an epidemic-like fashion owe their existence to the same agency of suggestion and imitation.

### AUTO-IMITATION.

The child's own diseases influence its psyche even more than do the ailments of others. The effect of the original organic disease may be a deterioration of the whole organism or of the nervous system; perhaps in most instances the psychic alteration being the causative factor of the subsequent disorder. This is pain as a rule; it is, so to speak, the reverberation of a previously actual pain that accompanied some organic disturbance, but after the complete cure of this organic disease became fixed as psychalgia, as douleur d'habitude (Brissaud's) habit pain. Such disturbances represent a condition, brought about by autoimitation of the original disease; it is the psychogenic "declaration of permanence" (Bruns) of the previous subjective symptom of an organic disease, the psychogenic residue.

Thus, after a cure of acute rheumatic polyarthritis, hysterical pseudorheumatism may make its appearance, the nervous nature of which might be recognized from the entire negative objective findings, perhaps, from the presence of paroxysms of various other pains, of vertigo, twitching of muscles, singultus, attacks of heart palpitation, etc. These arthralgias may be so intense as to forbid the slightest touch while the child is aware of it, but disappearing entirely during sleep, so that the child may even lay upon the very extremity. Likewise, there will be no painfulness upon pressure if the child's attention is diverted. In other cases the painful sensations appear and persist subsequent to a perhaps insignificant trauma or at any location of the body that was the site of an operation. An appendix operation, for instance, not so infrequently is followed by such psychogenic neuralgias in the environment of the normal and perfect scar, especially if the solicitous parents imprudently and permanently call the child's attention to this location. In the same category is the preservation and continuation of anomalous positions of joints (stiffness contractures) that children may manifest subsequent to the cure of organic pathological joint processes, as they have been mentioned before, or of furuncles. Cramer and others observed hysterical torticollis after lymphadenitis acuta (*l. c.*, page 56). It may not always be easy to decide at what time the organic stage becomes merely psychogenic, for pains of organic cause may not give clinical findings.

Recurrences of infectious chorea are far from being rare; however, a number of apparent relapses are not to be considered as genuine (infectious) chorea minor, but as its hysterically automimicked, aped picture. The distinction may *prima vista* be very difficult or impossible, but its nature is often recognizable from the rather sudden onset, the short duration and speedy cure by some suggestive treatment, and by the lack of muscular hypotonia; or, perhaps, from the presence of other hysterical manifestations, though both conditions may be combined. Among other irritative symptoms blepharoclonus and blepharospasmus after the disappearance of the primary disease may be mentioned. As a rule, it follows a reflex blepharospasm, due to inflammatory processes in cornea or conjunctiva or to a foreign body and persists, and it then represents the "declaration of permanence" of the previous state. By its intractability and other featurs it approaches the maladie des tics convulsives and the stereotypias. Respiratory troubles of hysterical nature that simulate diseases of the respiratory organs not infrequently develop from corresponding organic diseases, through the psychic "declaration of permanence." A child who has suffered from tachypnea and dyspnea, accompanying an extensive bronchitis, may later, when affected with a slight catarrhal affection, produce the same manifestation by autoimitation and hysterical reproduction of the former symptom (Thiemich). Or even after or during recovery from laryngitis, bronchitis, etc., the little child may burst forth into violent coughing, while in the physician's office, though it is without coughs for a great part of the day while at play. Likewise may the vague pains in the chest after pneumonia or bronchitis, or aphonia after tonsillitis and laryngitis be merely the psychogenic residuum.

Also spastic cough, stridor, and asthma-like attacks may, as I have seen, be of auto-imitative nature, the recognition of which may prove important for the treatment. The mimicry of pertussis attacks even months after the subsidence of the infection, at a slight irritative affection of the respiratory tract, as from bronchitis or pharyngitis, is rather a frequent occurrence. The process of facilitation, a certain degree of "Bahnung" of the nerve tracks in use in the cough reflex and its characteristic discharge, comes here in consideration; *i.e.* the nerve tracks, that for weeks or months during the whooping cough have been in constant use, become "beaten tracks," over which the slightest impulse will tend to take its course; the one branch line of the reflex arch being the nervus laryngeus superior. In whooping cough we may assume two phases: the first, in which the characteristic attacks have an organic cause, the other merely of neurogenic conditions (Bahnung). That also a psychogenic factor may occasionally be present must be inferred from those cases where suggestive therapy (faradization) resulted in surprisingly rapid cure.

To this process of "Bahnung," the law of which is really the law of habit, must be attributed a certain rôle in some processes of "declaration of permanence," as, for instance, in blepharospasm or in some tics.

Not so infrequently organic gastrointestinal affec-

tions are followed by various sensations in the abdomen of psychogenic, autoimitative origin, or diarrhea of any cause gradually may turn into one of merely neuropsychic character, *i. e.* dejections, that are frequent, though otherwise normal; however, when the frequency may disappear, when the child's attention is engrossed otherwise by play, visiting friends, etc. These cases may almost immediately yield to a faradic treatment, though they had proved very refractory to the various styptics and dietary regimens. Also the subconscious or unconscious remembrance of its own previous act of vomiting may suffice to induce the child to transform this mental picture into the corresponding muscular action, whenever opportunity offers itself. Anorexia as psychogenic residuum may reach serious degrees.

The autoimitation of previous diseases of organic nature, the fixation of a symptom in the subconsciousness, indeed often is directly cultivated and fostered by the overanxiety, morbid solicitude, overindulgence and imprudence of some parents, who would yield to every desire and wish, however foolish, of the sick child, and cannot in their belief sufficiently multiply their manifestations of parental care and sympathy; so that there seems to the child to accrue more advantages from being sick than from being healthy. Everyday experience shows that the child's psychic reaction from slight injuries depends on the attitude of the surrounding persons: the child will soon forget his pain, when met by a smiling face, but will even cry harder from seeing worried, frightened faces. Indeed, there are not a few nervous, hysterical mothers who rather indulge in the fact that the general interest is centered on some unusual manifestation of the child's sickness, and who, as it were, bask in the inordinate vanity of being interesting to others and of being sympathized with and spoken about. Clinical pictures of this character in such environment, it must be conceded, may border on conscious simulation or may be considered as downright simulation; though in regard to this possibility we must not lose sight of the fact that simulation itself may often be the expression of a pathological character, the psychically normal child having generally little proneness to sham disease.

The observations gathered here will suffice to convey an appreciative idea of the peculiarity of these states in their more important and common forms. The varieties, modification, and possibilities cannot be exhausted, and manifold deviations and combinations as protean as the pictures of hysteropathology itself may occur. The phenomena represent an interesting chapter not only of theoretical physiopsychology, but have an important bearing upon our therapeutic and prophylactic considerations and pedagogic principles. They emphasize our duty to familiarize ourselves more with the normal psychic life of childhood and its dispositions, so that we may successfully combat faulty tendencies by timely education and lead the all-important instinct into the channels of the good, noble, and beautiful. They remind us of Hecker's words, that "the human race * * * moves in body and soul as an individual Whole."

## ALCOHOL AND RACIAL DEGENERACY.

By L. MERVIN MAUS, Colonel, Medical Corps, U. S. A.
department surgeon, eastern department.

THE widespread custom of using alcoholic beverages is a perplexing and difficult problem to attack, on account of the prestige it holds with a large number of men and women of social prominence who still retain very liberal views regarding their use. Many people believe drinking essential to sociability and good fellowship, while others drink because they have inherited a weak and unstable nervous system from drunken parentage and are unable to resist its craving.

From time immemorial man has used some potent narcotic to increase the joys of life or deaden the edge of sorrow. The ancient monuments of Egypt show the use and abuse of alcohol, and the oldest Chinese manuscripts contain records of drunkenness. In the Vedas we find prayers to the Deity beseeching him to descend to earth and enter into a drunken orgy with his followers so that he might grant their prayers.

The hereditary effects of alcohol have been recognized from the earliest times. Plato forbade newly wedded couples to drink, knowing that drunkenness begat drunkards. Aristotle taught that drunken mothers brought into the world children like themselves. Both Buddha and Mahommet understood the degenerating influences of alcohol and interdicted its use through religious dogmas. Diogenes declared that stupidity in children resulted from intoxicated parents, and we are informed by mythology that Vulcan's lameness was the result of Jupiter's intemperate habits.

Dr. Norman Kerr says: "Men and women of the highest culture, the purest life, the most exalted aims, have become reckless drunkards. The clearest minds, the keenest intellects, the most subtle reasoners, have been enslaved by alcohol. The warmest hearts, the kindest souls, the most unselfish spirits have been transformed under the siren influence of this 'bewitching spirit' into the coldest, most cruel and selfish votaries at the shrine of Bacchus."

There are multitudes of people of both sexes, and in all positions of society, who enter the world with the "hallmark" of alcohol stamped upon them and spend their lives in fighting to lead a sober life, and there is no more pathetic sight on earth than to see these poor blighted souls endeavoring to elude the fearful temptations which beset them on every side. Thousands of those who were born under alcoholic influences finally drift into the habit and pass away at an early age.

Occasionally we find brilliant but warped minds among the degenerates of alcoholic families, many of whom live on the borderland between sanity and insanity. Some of them may be wonderful geniuses, brilliant orators and writers, but they are a strange, erratic people, who rapidly pass across the horizon of life after leaving a dazzling but evanescent trail. They are the last members of a once gifted family and, like the flicker of a candle, burst into a full blaze before extinction.

Following the general use of whiskey as a beverage fifty years ago, we find that many of the prominent families of the country have become extinct. The progeny of such families became drunkards and died childless or left children cursed with some form of degeneracy which rendered fertility impossible. It is only necessary to search the records of the noted families of both North and South to find that alcohol has been the underlying cause in the majority of those which have passed out of existence.

The moral, mental and physical condition of children is largely dependent upon the health and character of their parents. It might be said that the fate of every child which enters the world is written on its forehead, because its fortune for good or bad is settled in advance by the character and habits of its parents. How far this determining influence may extend it is impossible to say, but certainly in many cases for generations.

Many who have used alcohol for years notice an absence of vigor and freshness, which only returns after months of abstinence. One of the earliest indications of alcoholic poisoning and permanent injury is severe fatigue and breathlessness on slight exertion, or a disinclination to normal effort. It is not a pleasant thought to feel that we are dying daily through the influence of wine, beer, whiskey and brandy, but that is exactly what is taking place in every man and woman who indulges regularly in intoxicants, even in small quantities.

The custom of taking a drink to stimulate intellect and facilitate speech is logically unsound. No mind is capable of making its best effort when under the influence of even a small amount of alcohol. Helmholtz, the cultivated physicist, declared that even in small quantities alcohol served to banish from his mind all possibility of creative effort or the solution of any abstract problem. For such reasons thousands of the most progressive intellects of the country have entirely abandoned the use of alcoholic beverages.

Premature senile decay and loss of memory are the marked results of alcohol among its regular habitues. The loss of memory is progressive and appears in the form of verbal amnesia. Regular and constant drinking, although in moderation, also causes the loss of judgment and lessens clear and consecutive reasoning.

Alcohol interferes with the process of metabolism, inasmuch as it possesses an affinity for oxygen, and hence robs the tissues of this important element, which is so deeply concerned in ridding the system of the poisonous wastes which clog the body and invite chronic organic diseases.

The hindrance and delay in tissue changes from this cause lead to increased weight, arteriosclerosis and general mental and organic degeneracy with marked waning of the intellectual faculties. A definite alcoholic egotism is noted among many regular drinkers, whose weakened constitutions and intellects are apparent to every one but themselves. This condition is not infrequently found among confirmed drinkers occupying important positions in business, governmental and public life.

The great scientist Metchnikoff has taught us that the white corpuscles of the blood are the natural guardians of health. They have the normal function of resisting and destroying malignant germs which gain entrance into the circulation and tissues of the body. When influenced by alcohol they lose this power of defence and become powerless against the invading enemy.

Two Belgian observers, Massert and Bordet, found that alcohol strongly repelled the white corpuscles, and that small quantities circulating in the blood prevented their migratory character when called upon to functionize. Abbott found this peculiarly the case in erysipelas and cellulitis. The blood plasma has also a defensive quality of guarding the body against malignant germs, which is destroyed by alcohol.

This occurs especially among many drinking men between the ages of 40 and 50 years, who are handicapped when attacked with pneumonia, influenza, typhoid fever or any disease of microbic origin in which depressing toxins are generated. A man from 40 to 60 years of age should enjoy the most useful part of his life, if properly born and has taken care of himself, especially with reference to alcohol and other poisons, such as morphine, cocaine, or syphilis.

In view of what medicine has taught us regarding the effects of alcohol on racial degeneracy, it seems inconceivable that so many of her disciples should continue its use. Physicians certainly know that they enjoy no advantage in immunity over the hundreds of thousands of men who die annually from its effects. Besides, they must be aware of the fact that the constant use of alcoholics results in intellectual stagnation, if not regression, a cessation or diminution in mental growth, as the addict approaches middle life. Many drinking men who started out in life with brilliant minds are far outstripped in the battle of life by the constant plodding mediocre.

There remains no longer any doubt regarding the ruinous effects of alcohol on the human race, and it becomes not only the duty of the state, but the duty of every intelligent man and woman to join in the crusade against the common enemy. Society must prevent its own ruin and degradation at any cost, and defend the innocent members of the community against the ravages of the great destroyer, alcohol. The country would be electrified if called upon to appropriate $2,000,000,000 annually to suppress some dreadful epidemic, and yet the American people are spending that sum every year in the interests of crime, disease and death.

During the past year there were about 2,000,000,000 gallons of wine, beer, whiskey, brandy, gin, and other alcoholic drinks consumed in the United States, which cost the people as many dollars. The

expenditure of this vast sum of money is not only materially responsible for the misery, poverty, robberies, murders and crimes of our people, but for hundreds of thousands of deaths and the large army of "intellectually dead," who are to be found in our insane asylums, feeble-minded and epileptic institutions.

Recent studies of the vital statistics of the country have revealed an alarming increase in the diseases of degeneracy, and it has become necessary to take an inventory of the moral, and physical stock of the people. This condition is principally due to intemperance, immorality and vice diseases, and unless there be a general reformation in the moral conscience and habits of the people our great republic, like ancient Babylon, Nineveh, Greece and Rome, will in turn wither and die.

From a careful study of the statistics of the country, it is believed that America is inflicted with nearly a million degenerates and criminals at a cost of at least $250,000,000 annually.

Among these unfortunates we find:

| | |
|---|---|
| Insane | 200,000 |
| Feeble minded and epileptics | 250,000 |
| Deaf and dumb | 100,000 |
| Blind | 100,000 |
| Juvenile delinquents in institutions | 50,000 |
| Paupers | 100,000 |
| Prisoners and criminals | 150,000 |
| Which gives a grand total of | 950,000 |

"Ill fares the land, to hastening ills a prey
Where wealth accumulates and men decay.
Kings and lords may flourish or may fade.
A breath can make them, as a breath has made;
But a good yeomanry, the country's pride,
When once destroyed, can never be supplied."

For this widespread national degeneracy we must look principally to the "racial poison," alcohol, which directly or indirectly is largely responsible for the majority of the mental and physical wrecks brought into the world. A generation ago the progeny of our people was fairly sound, because the high-minded mothers of the land rarely indulged in alcoholic beverages. But to-day the growing tendency of the youth of both sexes to the use of cocktails and other intoxicants is becoming the greatest menace of the age, and threatens the integrity of the race.

Not only does alcohol destroy the unfortunate habitué, mentally and physically, but it ruins the happiness and prosperity of the family. Those who drink do not seem to realize that the alcoholic habit not only spells suicide by slow degrees, but entails a curse on the children which descends to the third and fourth generations. When the general public learns that the diseases and evil traits we possess were transmitted by those who are mouldering in the grave, thousands of defective sons and daughters will curse the memory of their dead parents who fastened upon them the seeds of degeneracy.

Dr. L. D. Mason, of Brooklyn, from a study of 7,000 inebriates, found that 60 per cent. had alcoholic ancestry, either parents or grandparents. Legrain, of France, after an exhaustive study on this subject came to the same conclusion. A great many of the greatest authorities who have spent their lives in the study and care of alcoholics agree that from 40 to 70 per cent. of these unfortunates owe their condition to heredity, among whom may be mentioned, Crothers, Horstley, Sullivan, Kerr and a host of brilliant American and European physicians.

One of the Lord Chief Justices of England once said, "If sifted, nine-tenths of the crime of England and Wales could be traced to drink." There is little doubt but that this is true of every country and land where intoxicants are in common use. The famous investigation of the Massachusetts Bureau of Labor Statistics revealed the startling fact that 84 per cent. of all the criminals under conviction in the state owed the condition, which induced the crime, to intemperate habits.

Dr. Hatch, superintendent of the State Hospital, California, points out alcohol and alcoholic heredity as the principal predisposing cuases of insanity. We have the testimony of Berkeley, Spitzka, White, Sullivan and a host of other brilliant and reliable alienists. Madam Tarnowsky found parental alcoholism in the parents of 82 per cent. of the women of the town and Workmüller in 42 per cent. of juvenile criminals of weak intellect.

The child born of an intoxicated parent never equals the child born of sober parentage and rarely rises above mediocrity. While there is more or less immunity to the alcoholic addict, there is never immunity to the parental germ plasm or the maternal ovum, which is invariably injured by the slightest dilution of alcohol in the blood.

Bezzola found that 35 out of 70 idiots were conceived during the wine harvest of fourteen weeks in which the Swiss carouse, while the remaining 35 idiots were conceived during the rest of the year. Leppich claims that he has observed ninety-seven children who were conceived at the time one or both parents were intoxicated, only 14 of whom were born without noticeable defects. Dr. W. C. Sullivan reports seven authentic cases of this character, one of whom was stillborn, while the remaining six died only a few weeks after birth.

The disorders of development among children from parental intoxication vary greatly in character. They range from moderate enfeeblement in mental and physical growth to the lowest grade of idiocy and monstrosity. According to Dr. W. C. Sullivan, 55 per cent. of the children of alcoholic mothers are stillborn, or die before attaining their second year, while many of those who survive are epileptics, feeble-minded, or idiots. A large number of the remainder suffer from a peculiar degeneracy of brain and nerve supply, which places them in that large and sad army of "erratics."

Tuberculosis is also a common result of intemperance and is far more common in drinking communities than in prohibition territory. We frequently find the children of the intemperate afflicted with hip-joint disease, spinal affections, swollen joints, glandular enlargements, scrofula, and consumption of the lungs. The International Congress on Tuberculosis, which met in Paris in 1905, passed the following resolution: "That in view of the close connection between alcoholism and tuberculosis this congress strongly emphasizes the importance of combining the fight against tuberculosis with the struggle against alcoholism."

Alcoholism is a very common cause of suicide. Prof. Hillier, of Kiel, reports 135 suicides among 230 alcoholics, whose deaths came under his observation. Dr. Sullivan reports that in 220 suicides or attempts, 172, or 78 per cent., were due to alcohol. While it is impossible to secure correct statistics, it is more than probable that hundreds of "floaters," annually found in the harbors of our large cities, committed suicide as a direct or indirect result of alcohol.

Many who denounce ardent spirits claim beer a wholesome and sustaining food. Beer drinkers are especially liable to fatty and enlarged heart, diseases of the liver and kidneys, complicated with dropsy, arteriosclerosis, gout and rheumatism. As sequelæ of beer drinking we find an infected and loaded circulation, embarrassed respiration, functional perversion, hepatic and renal congestion, with a stupor tending toward paralysis and a diminished vitality which invites disease and death.

The mortality of brewers between the ages of 50 and 60 is about three times as great as that of individuals who follow the ordinary occupations of life. In fact, the mortality of liquor dealers and brewery men, with few exceptions, is greater than that of any other occupation. Doctors Bauer and Bollinger, of Munich, report that beer drinkers' heart of that city causes one death to every sixteen from other causes. Instead of being a healthy drink, malt beverages are not only unwholesome luxuries with no food value but are factors in blood vitiation and a fertile cause of organic degeneracy and death.

The critics say that something is the matter with prohibition as it does not prohibit. In reply, the prohibitionist would like to know what is the matter with Kansas. During the recent drought in the West when asked whether they wanted assistance, the governor replied that Kansas with a tidy bank account of $200,000,000 could weather worse storms than the drought of last summer without hardship.

In 97 of 105 counties there were no insane. In 54 of these counties, no feeble minded; 96 counties with no inebriates; 38 county poorhouses were empty; less than 600 paupers in the state; the jails in 53 counties empty, and 65 counties had no prisoners serving time in penitentiaries. Some counties have called no juries to try criminal cases for 10 years. Instead of mortgages, as was the case 20 years ago, the people of the state hold $67,000,000 mortgages. Illiteracy is only 2 per cent, next to the lowest in the land. Decidedly something is the matter with Kansas, and that is constitutional prohibition.

The last census of the United States, 1910, showed 187,454 institutional cases of insanity and probably enough cases under private care to raise the number to 200,000 at the least. The cost of buildings to house these unfortunate intellectually dead aggregates $250,000,000, while the annual outlay for their maintenance amounts to $50,000,000.

In India, with a population of 300,000,000, insanity is almost infinitesimal compared with that of Great Britain, notwithstanding her scourges of famine, plague, and pestilence. China, with a population of 400,000,000 has an exceedingly low rate of mental alienation; in fact in no part of the world is there less mental trouble. Mulhall, in 1903, stated that in India there was one case of insanity to 4,340 population, while in the United States there was one to 490 people.

New York State, with a population of 9,113,000, has 31,265 cases of insanity, 1 to 290 as compared with 15 southern states, Kentucky, Tennessee, Alabama, Mississippi, Texas, Oklahoma, Arkansas, Louisiana, New Mexico, Florida, Georgia, South Carolina, Virginia, and West Virginia with a population of 27,886,000 and only 31,734 cases of insanity, or 1 to 880.

While other causes no doubt influence the large ratio of insane in the state of New York, 1 to 290 of the population, as compared with the 15 states of the south and southwest, 1 to 880, it is believed that the great preponderance of liquor dealers in the former, 35,275, over those in the 15 states, 12,000, is the principal cause of the difference.

The relative proportion of insanity in the following states is in keeping with its legislative policy regarding salese of intoxicants:

| | |
|---|---|
| Kansas | 1 to 873 |
| Indiana | 1 to 609 |
| Maine | 1 to 590 |
| New Hampshire | 1 to 473 |
| Ohio | 1 to 449 |
| Illinois | 1 to 437 |
| Rhode Island | 1 to 436 |
| Michigan | 1 to 419 |
| Wisconsin | 1 to 376 |
| Virginia | 1 to 375 |
| Connecticut | 1 to 311 |
| New York | 1 to 290 |

In order to remove this great racial curse, it becomes necessary to educate the masses and secure prohibition. Teach total abstinence in every school, college and university throughout the breadth and depth of the land. Teach the young men to avoid clubs in which alcoholic drinks are sold. Drinking clubs are responsible for the ruin and downfall of thousands of our most promising young men and women and should be abolished.

No woman should marry an intemperate man with the idea of reforming him. It is a dangerous risk and nine times in ten will end in misery and sorrow. Alcoholics, as a rule, are hereditary degenerates and are no more able to resist the call for alcohol than a man with ague can prevent shivering.

Young men should likewise inquire well into the character of the woman before taking a partner for life. Study well the character and family history of the parents, remembering that the daughter is a chip from the same block and will develop on similar lines. Avoid the silly young woman, who belongs to the moron class and cares little beyond dress and the frivolities of life. Such women make poor wives and miserable mothers, should they by chance have children. Many women of this class are charming and bewitching but are hopeless blanks.

In the history of the world there never was a time when men and women of strong character and fearless courage were more greatly needed—ardent apostles of the higher standards of life, to counteract the vicious tendencies of the age, through religious, moral, and temperance instruction, adopting "A sane and healthy nation" as the motto for their war cry.

## THE THERAPEUTIC VALUE OF CROTALIN IN THE TREATMENT OF EPILEPSY.*

By THOMAS J. MAYS, M.D.,

PHILADELPHIA, PA.

Crotalin is the dried, yellow residue of the venomous secretion of the American rattlesnake, and the physiologic analogue of the human saliva. All snake venoms are possessed of like physiologic properties, and Felix Fontana, an Italian investigator, was the first to make a profound study of this substance as early as 1787. Some of these venoms have been given by the mouth by our Hahnemannian colleagues for almost a century in the treatment of various disorders, but it is the writer's belief that he was the first to inject snake venom

*Read before the Northern Medical Association of Philadelphia. November 28, 1913.

into the human system for the relief of epilepsy, or of any other disease.

Pharmacologically, crotalin is closely allied to the cyanides. In fact, it was largely due to a study of the action of the latter that the writer was led to investigate the clinical properties of rattlesnake venom. By comparison it will be seen that the following effects which are produced by hydrocyanic acid have their exact equivalents in snake poisoning. In animals: Difficult breathing, dizziness, spasms, convulsions, and death through respiratory paralysis.

Small doses in man cause a flow of saliva, tendency to vomit, difficult swallowing, dizziness, laborious respiration, constriction of the chest, and palpitation of the heart.

Poisonous, but not immediately fatal doses, bring about slow and labored respiration, cold sweat, thready pulse, nausea, twitching, convulsions, and death through respiratory paralysis, while the heart continues to beat. After death the blood is uncoagulated.

The back of the forearm has been selected as the site for the clinical administration of this drug, although there is no reason why the upper part of the arm, or shoulder, or back, in close proximity to the neck should not be utilized. The needle is well introduced through the skin and underlying fascia, and, in order to avoid throwing the solution into a blood-vessel, it is important to withdraw the needle a very short distance before the injection is made.

The immediate local effects after hypodermic injection of crotalin are a slight burning, stinging pain at the seat of injection, with general tingling and numbness along the course of the ulnar nerve, or a darting sensation along the shoulder. The pain is not severe and of short duration, as can be attested by anyone who has experimented with it on his own arm, as was done by the writer at the inception of the crotalin investigation. In the course of an hour or two, and sometimes sooner, considerable edematous swelling occurs at the seat of injection, which may radiate as far as the wrist and the elbow, especially in the first-injection cases. Neither the pain nor the swelling become excessive in the great majority of instances, nor has the writer experienced a single abscess, nor a serious complication of any kind in probably more than ten thousand injections which he has given. In the case of undue pain or swelling, the application of a cloth well soaked in a saturated solution of magnesium sulphate will alleviate the trouble.

*The Essential Nature of Epilepsy.*—Whatever the cause of epilepsy may be, it must be admitted that it is fundamentally a nervous affection, and that one of its most prominent and active manifestations consists in a disturbance of the regulating center of voluntary muscular motion, resulting thereby in an irregular clonic contraction of the general muscular system. Whether the original impulse that incites this originates in the cortex or in the periphery, matters not, so long it is true that no genuine and complete seizure can occur without implicating the muscular co-ordinating center in the medulla oblongata, which is also known as the convulsive center. In other words, while irritation of the brain cortex, or of an extremity, may initiate a seizure, the course pursued by an impulse so generated eventually involves the controlling center of muscular motion in all full-developed seizures. This center being in such close proximity to those which control respiration, circulation, swallowing, vomiting, etc., these functions also become implicated, and as a result we have embarrassed and stertorous breathing, accelerated heart-action, salivation, vomiting, etc.—symptoms which accompany almost all convulsive processes.

It may be said, then, that the essential nature of epilepsy resides in a hyperirritability of the nerve centers to which reference has already been made, and which being excited by stimulants or irritants, either on the inside or on the outside of the body, call forth a disproportionate number of alternate contractions and relaxations of the voluntary muscular system, as one of the principal manifestations of this disease.

This hyperirritable mechanism is also responsible to a large degree for the existence of the various forms of seizures which accompany this disease. Thus the *petit mal* seizures are the direct result of a higher degree of irritability of the musculomotor center, than that which obtains in the *grand mal* seizures, and as a sequence the nerve discharges emanate from a less stable base, have less volume, are less accumulative and more frequent, and are more readily provoked in the former than in the latter.

In connection with this line of thought it may be said that there is one point in the pathologic process of epilepsy which is seldom given the consideration which it deserves, and that is the trivial link which divides the paroxysmal from the nonparoxysmal state in this disease. During the interval between two paroxysms the susceptible nerve area, although in apparent health, suddenly becomes transformed into a violent form of disease, but resumes its normal function as soon as the paroxysm is over—showing seemingly that it requires but a minute change in the morbid process to bring about repair in the breach. It also gives us reason for believing that health and disease are not divided by hard and fast lines, but that one shades off in the other. That which is health at one moment may be disease at the next, and *vice versa*. The size of each territory depends on the degree of bodily resistance. If this is weak on the side of health, disease extends its area or its intensity, and if this is weak on the side of disease health will extend its domain and crowd out disease.

Figuratively, the action of crotalin may be likened to the form of a pyramid, the ascending line on one side of which represents its physiologic or its stimulant action, and the descending line on its opposite indicates its pathologic, or toxic action. Its physiologic effects are exhibited by the increased vigor and strength which it infuses, and its toxic influences shows itself in tetanus, convulsions, and paralysis. When crotalin stimulates a nerve tract which has departed from its normal level, it gradually forces the line of resistance or of health upwards and in the direction of disease until the apex of the pyramid is approached. This constitutes the danger line of poisoning, and must never be crossed. It thus displays an uplifting power which diffuses a health-giving influence, for example, into the functionally deranged center of muscular co-ordination, and forces it into a healthier attitude. The prototype of such action is found in strychnine when it corrects the disordered contraction of the heart muscle. Thus irregularity, palpitation, etc., of this organ manifest themselves in profligate and extravagant muscular contractions—a miniature epilepsy—wholly due to a loss of nerve restraint, yet strychnine comes in often and

restores this defective motion solely by invigorating the function of the cardiac nerve center and its radiating branches.

Proper dosage is an important matter in the administration of crotalin in epilepsy. It has already been observed that epilepsy is largely a question of hyperirritability of the nervous system, and since the nervous system is very susceptible to the action of this drug, it is very obvious that the amount which is prescribed must be adapted to the various degrees of irritability which are present in the several types of this disease. Thus, patients who suffer from petit mal seizures alone, even when these are associated with the grand mal variety, are, as a rule, more sensitive to the action of crotalin than those who suffer from the grand mal variety alone. Children, of course, require smaller doses than adults, but the child with petit mal seizures is also more susceptible to it than the one having the grand mal seizures. Neglect to bear this point in mind, especially in the beginning of treatment, often leads to failure.

Evidence of such mishap is found in the following incident: A patient suffering from both forms of seizures, received minimum doses of crotalin in the beginning of treatment, and in the course of a month the seizures began to diminish in number. But as the treatment progressed, and the former doses no longer produced their local reaction, which was supposed essential to secure the full therapeutic effect of the drug, larger doses were resorted to, and before long the diminution of the attacks ceased, and became more aggravated than they were before the treatment was begun, and the drug was, of course, abandoned. About a year later the treatment of this case was resumed with smaller doses, which were continued for some time, and then gradually increased, and from recent information it is learned that he is making satisfactory progress both in the diminution in the number of fits and in the improvement of his mental condition.

The average hypodermic dose of crotalin in epilepsy is five minims of the solution, or gr., 1-100, although this is too much for a beginning dose in the great majority of cases. In patients having the *petit mal* type of seizures, it is always advisable to begin with one or two minims, gr., 1-500, or gr., 1-250, given every fourth or fifth day. The initial dose should be continued for two or three weeks and then gradually and slowly increased to four or five minims in the course of six weeks or two months. This dose is to be continued for three or four months, or longer, and if it be deemed advisable it may be increased gradually in time to ten minims, or gr., 1-50, which should hardly ever be exceeded, and should, if given, not be persisted in for a long period at any time. If at any time during treatment the seizures increase in number or in intensity beyond their original limit, the dose should be diminished.

The following formula has been employed in making a suitable solution for hypodermic purposes:

℞ Crotalini .....gr. 1.
Glycerini .....min. 100.
Aquae destil.....min. 400.
℔ Five minims represent gr. 1-100.

In addition it is the writer's privilege to refer in a statistical way to 64 cases of epilepsy treated with crotalin, and which have been collected from the practice of his colleagues, and from that of his own, and which he hopes to report in greater detail in a future publication. These cases have been treated for periods varying from two to seven months, and are here divided into two groups—one consisting of 38, and the other of 26 cases. The number of seizures which the patients had is taken as a criterion of the *statu quo* of the disease at any given time, and in each case the number of seizures was noted during as long a time before the treatment was instituted as that which was occupied in the administration of crotalin.

Of the 38 cases there were 14 who had grand mal seizures; one with petit mal seizures, and 23 who had both types of seizures.

The total number of seizures of the 38 patients before the commencement of the crotalin treatment was 1291, and during the time of treatment there were 761 seizures—or a decrease of 41 per cent. The 14 grand mal patients had 789 seizures before, and 367 during the crotalin treatment—or a decrease of 55 per cent. in the seizures. The one petit mal case had 60 seizures before treatment, and 112 during treatment—an increase of 86 per cent. of seizures. The 22 patients with both forms of seizures had 442 seizures before, and 282 during treatment—a decrease of 36 per cent.

It is also of interest to trace the influence of different doses of crotalin on the various types of seizures. Thus in 4 cases of grand mal, the maximum dose of which ranged from gr. 1-35 to gr. 1-25, the seizures before treatment numbered 373, and during treatment 110—a decrease of 70 per cent. in the seizures. In five others of the same type, whose maximum dose was gr. 1-50, before treatment were 310, and after, 128—a decrease of 58 per cent. In five others of the same type, whose maximum doses were from gr. 1-100 to 1-125, the seizures before treatment numbered 267, and during treatment 107—a decrease of 60 per cent.

In six patients suffering from both types of seizures, whose maximum doses ranged from gr. 1-25 to gr. 1-35, the number of seizures before treatment was 85, and during treatment 54—a decrease of 36 per cent. In 8 other patients of the same type, whose maximum dose was gr. 1-50, the seizures before treatment numbered 236, and during treatment 126—a decrease of 42 per cent. In three similar patients, whose largest dose was gr. 1-100, the seizures before treatment were 13, and during treatment 6—a decrease of 53 per cent.

The one petit mal case, whose seizures increased 86 per cent., received the maximum dose of gr. 1-25, and it is very probable that this dose was excessive.

From the foregoing it appears that the appropriate maximum dose of crotalin in grand mal cases ranges from gr. 1-35 to gr. 1-100, and cases with both types of seizures the indications here point to gr. 1-100 as the maximum dose. Of course it must be borne in mind that in all the cases referred to above the beginning of treatment was made in small doses.

The group of 26 demands a somewhat different analysis. They are institutional cases, and were treated for seven months without crotalin, and for the succeeding seven months 13 received the different bromide compounds, calcium lactate and crotalin, while 12 were treated with crotalin alone—a most impartially and scientifically conceived experiment.

Now, by dividing the first seven months in which no crotalin was given into two equal parts of three and a half months each, it will be found that the

total seizures of the first half period were 2108, and in the second half 2610, showing an increase of 20 per cent. in the seizures during the first seven months. The same analysis applied to the seizures of the 25 patients, of whom a complete record is given during the last seven months, shows a total number in the first half period of 3365, and in the second half period 3265, or a diminution in the seizures of 10 per cent.

On the other hand the seizures of the 13 patients who received crotalin, the bromides, and calcium lactate, during the last seven months, show that 2234 seizures took place in the first, and 2234 in the second half, or an increase of 0.8 per cent. of seizures. While the 12 patients who received crotalin alone during this period had 1431 seizures in the first and 998 in the second half period, showing a diminution of 30.39 per cent. in the seizures. This seems to indicate rather conclusively that the exclusive use of crotalin gives by far better results than when it is given with the bromides and the calcium lactate.

Now, if the above deductions are confirmed by further experience, the following therapeutic points will be established in the administration of crotalin:

1. As a rule, crotalin has the power of relieving the paroxysms of epilepsy if given in appropriate doses.

2. The average maximum dose lies between gr. 1-100 and gr. 1-50, although the former must be preceded by minimum doses in probably every case.

3. Crotalin has more power to relieve epilepsy than the bromide compounds.

## SOME FURTHER EXPERIENCES IN THE EXTRACTION OF IMMATURE CATARACT BY THE HOMER C. SMITH METHOD.

By HOWARD F. HANSELL, M.D.,

Philadelphia, Pa.

The success attending the application of the Homer C. Smith method of treatment to two unusually important cases of immature cataract has been so satisfactory that I feel warranted in presenting the subject for consideration. It may be said that the results would have been equally good without the preparatory capsulotomy and by the ordinary operation. Yet I can't help believing that the ordinary extraction would have been attended by retention of lens debris with possibilities of iritis, dense membrane in the pupil and other obstacles to a useful eye. However, my experience does not warrant emphatic advocacy of this operation, although I believe it to be a solution of the vexed question of operative treatment of immature cataract. There may be objections to be urged against it. I have operated upon ten cases, five of which were reported in the discussion of Fridenberg's paper, which was read before the American Medical Association, June, 1912.

Extraction of the lens in its capsule has not found favor among American operators. I have never performed an Indian extraction and think I never will. On the other hand, the method practised by Stanculeanu of extracting the lens in its capsule has certainly much to recommend it. By means of a pair of special capsule forceps he grasps the lens capsule on each side of the center and by a gentle, persistent sideways movement dislocates the lens and capsule out of its fossa and then expresses it by well-directed and regulated pressure through the cornea. The operation is thus described by W. Likely Simpson, in the *Ophthalmic Record*, May, 1913. The incision in the cornea is a trifle larger than the ordinary. The puncture and the counter-puncture are made well back in the limbus and the knife is brought out at the anterior edge of the upper limbus; he makes a small conjunctival flap; performs iridectomy and effects dislocation of the lens by one, two, or three steady side movements: expression. Should the capsule be torn without dislocation of the lens, the forceps are withdrawn and the operation thereafter is continued according to the usual procedure. With this operation, also, I have had no experience, but I believe its advantages over the Indian method are decided.

Having, therefore, mentioned the two principal intracapsular operations and dismissed them as impracticable in the light of present experience in America, we are still face to face with the problem that has so often and so seriously been discussed, namely how to treat immature cataract. The disadvantages, annoyances, deprivations, and depression of slowly advancing blindness are familiar. No argument is needed to convince us of the need of an operation that may be safely and successfully performed at the beginning of the loss of usefulness because of diminishing sight. The artificial ripening operations are not generally practised because of their danger. Immature cataracts differ in their degree of hardness as much as in their opacity, and while it is generally true that advancing years mean hardening of the lens, the exceptions to the commonly expressed opinion that a lens in an individual over sixty years of age is sufficiently sclerosed to assume that its extraction will be unattended with the retention in the anterior chamber of soft cortex are so numerous that it is quite impossible to state accurately before operation the immediate result of extraction. It has been my practice in the past two or three years to irrigate the anterior chamber in all cases of extraction of immature cataract, and in practically all those believed to be mature. A clear pupil following expulsion of the lens is no criterion. The remaining cortex may be perfectly clear and so will escape even careful inspection until the eye is opened a day or two later. In following the Homer Smith method I do not deviate from this rule.

Of the five unreported cases in which preparatory capsulotomy was performed I wish to dwell particularly on two which presented unusual difficulties in deciding the best course to pursue:

Case 1.—Mrs. F., aged 47, consulted me in October, 1911, stating that for three years vision had been slowly declining. She had consulted an oculist in a Southern city and had been a resident in his hospital for three months and had undergone both surgical and medical treatment for the eyes at his hands. At the expiration of this time vision was worse rather than better. She consulted other oculists, some of whom gave her an unfavorable prognosis and advised against operation. I performed preliminary iridectomy on both eyes and with a hyperopic glass vision was improved from 20/200 to 20/50. Both lenses were opaque only in their posterior layers. The nucleus and the remaining portions of the cortex of each were clear. From the history and condition of the lenses the diagnosis of choroidal cataracts seemed justifiable. Syphilis and diabetes were excluded from the etiology. Recovery from the iridectomy was prompt. In May of the present year the patient returned. Vision had declined to 5/200. The opacity had invaded the layers posterior to the nucleus extending out to nearly the circumference, while the remaining cortex and anterior section still retained their transparency. Extraction, successful both in its performance and sub-

sequent healing, was the only hope, but was one justified in advising its performance? After thoughtful weighing of the pros and cons I decided in the affirmative. I divided the capsule on May 8 and extracted the lens on the following day. The patient was exceedingly nervous and I was obliged to close the eye without irrigating the anterior chamber. The wound healed in forty-eight hours and there was no complication. Vision, six weeks later, with a correcting glass equalled 20/30 mostly, and the patient could read, comfortably, ordinary newspaper type.

Case II.—The patient was also a woman, aged fifty-five. I performed preliminary iridectomy on the right eye January 25, 1913. Vision equalled 20/200. The nucleus of the lens was opaque but the entire cortex was clear. By April 30 the opacity had advanced to include more of the cortex and vision had declined to 5/200. Preparatory capsulotomy was made May 1 and extraction the following day. In this case the anterior chamber was irrigated. In five weeks vision, with correcting glass, equalled 20/20.

The three other cases operated on presented nothing unusual. The patients were all over sixty, the cataracts were nuclear and immature and all were successful.

The technique of operation of preparatory capsulotomy has been described by both Smith and Fridenberg. The former advocates a special knife. My earliest operations have been done with the knife-needle of Knapp and the later with Zeigler's knife-needle, both of which answered the purpose admirably. The procedure is not unattended with danger. The difficulty lies in making the incision just deep enough to surely divide the capsule and the lens cortex immediately beneath it, and not to dislocate the lens. The form of the incision in the capsule is, in my judgment, unimportant. I have found it easiest to make two incisions which approach each other or meet at their upper extremities—much like the V-shaped incision of Ziegler in after-cataract. The aqueous in nearly every instance escapes, but this is of no moment. Smith advises the extraction within six hours of the capsulotomy—I have extended the interval to twenty-four hours.

A word of caution during the expulsion of the lens is not out of place. After the iridectomy, or if the iridectomy has been previously performed, after the incision, one should remove all pressure by the speculum and wait a moment. If the lens shows no intention of expelling itself automatically I introduce the capsule forceps, remove the central portion of the capsule and express the lens, but usually the successful opening of the capsule on the previous day will obviate the necessity of the introduction into the eye of any instrument after the iridectomy.

1528 Walnut Street.

## THE CASE AGAINST THE EUGENISTS.

By Joseph Eastman Sheehan, M.D.,

Orange, N. J.

Everybody to-day is talking about social progress. Physicians, ministers, lawyers, college professors, the ordinary layman and social workers are falling under the influence of eugenics. Little did Sir Francis Galton, who practically established a basis for a relative study of a better breed of humans, probably after taking the hint from Darwin, dream of promoting a league of faddists. There is nothing really new in the study of eugenics. Plato even taught its principles. In ancient times, however, they studied questions more scientifically; in our day questions of serious import must, in order to receive any notice at all, become fads. The motto of the eugenists: "The fittest must and shall survive" briefly sums up the creed of our present-day social and medical reformers. To breed human beings as one does plants and domestic animals may become, in the near future, a national issue, if the eugenists have their way. The men and women who are administering the estate's temporal and spiritual of humanity have undertaken a movement that does credit to their emotions, if not to their judgment.

Eugenics represents an effort to bring together those people who have complementary qualities and complementary interests, who are capable of maintaining congenital relationships in the present and creating able offspring in the future. "Selection and parenthood," declare the eugenists, "are the cradle of the future." Hence the individual who in the exercise of his choice overlooks their significance overlooks one of the most important responsibilities.

Nietzsche gave us the word "superman"; George Bernard Shaw defined it. This brilliant Irish wit and iconoclast holds that "the union of a physically sound Anglo-Saxon and an imaginative Jewess would in all likelihood bring into the world a superchild after Nietzsche's heart." We do not know whether the experiment suggested by Shaw has ever been tried, but there is every reason to believe that, when the eugenists succeed in Burbanking the human race, if they ever do, we shall have to love according to legal statutes. Love and affection will no longer have its place in Dan Cupid's curriculum. We might have laws commanding an Irishman to marry a Russian woman; a Frenchman to marry a Polander; an American to marry an Italian, etc.

The objectors to the theories of the eugenist schools maintain that Mother Nature has already forestalled the "new science." Under actual human conditions nature accomplishes in due time what the eugenists wish to accomplish in a minimum of time. Dr. Saleeby of Edinburgh strikes a new note in the "science" by his doctrine of materialism. Not everyone, however, can accept his teachings *in extenso*. Dr. Saleeby upholds the dignity of motherhood. He says that "life begins at home, and the true politics of the world is domestic science." He wages incessant war against infant mortality, for once "the life is in being it ought to continue in being. Once the unfit are in being, we must make the best of them." He then contends, rather ingeniously, "that it is the psychical element in man which has the best survival value, and this psychical element, moreover, is not merely intelligence, but it is also love. Without love no baby could live for twenty-four hours. Every human being that exists is the product of mother-love or foster-mother-love. No morals, no man. There is no wealth but life, and if the quality of life fails, neither battleships, nor libraries, nor symphonies, nor anything else will save the nation. Empires and civilization have fallen despite the strength and magnitude of their superstructure, and all because the foundations decayed."

Further objections against the eugenic "system" are made by the philosophers and theologians, who declare that the teachings of the Galton school are not ultimate enough. The churchmen declare "the root-cause of degeneracy to be sin, and the root-cause of betterment to be virtue." Will-stimulus is at the origin of the church's suggested race-improvement ideas. They also argue that what they

aim at and accomplish, though sacramentally, is the production of genius in morality. Aiming solely at the development of spiritual life the church is able to carry out her own system of eugenics. As a matter of positive eugenics she teaches that marriage is a sacrament through which is conveyed a divine strength enabling the married pair to perform all the duties of their state. As a matter of negative eugenics, she places impediments against undesirable unions. In imposing or in taking away impediments the church always puts religious considerations first, for if the sanction of religion is destroyed other sanctions are ineffectual.

Eugenists lose sight of the *moral* worth in man. They forget that the dominant factor in eugenics is for men and women to lead pure lives. It goes without saying, however, that the influence of eugenics may be exercised through legal statutes touching upon sanitary conditions, but religion will have to do its part with individuals as well as sanitary laws.

One of the chief mistakes made by eugenists is in believing that *social* improvement and *racial* improvement are one and the same. It is generally admitted that with no change in rational capacity the combined efforts of generations to better life might produce a change in our social structure, and it appears that by such process the actual achievements of mankind have been brought about.

Now nobody will deny that society is composed of men and women whose qualities determine the nature of their interactions. Since men and women are of mixed dispositions it follows that their qualities are very complex. To quote an eminent sociologist: "That which is absolutely pure lacks strength. And that which has strength to resist friction lacks absolute purity. You can't make a hard tooth of pure gold. Examine closely the life of Augustine, Francis of Assisi, a Washington, or even Lincoln, you find the alloy." It is the alloy that enabled these great men to do hard work in spite of friction and fighting. Circumstances, however, may decide whether the gold or the alloy is to show on the surface. The ultimate determinants that urge society to advance or retrograde are the qualities of individuals. The efforts that individuals make to improve their conditions and the social order about them are themselves the result of these qualities. Now the eugenists admit that the quality of the stock is of high importance. They likewise admit that natural selection is no longer capable of performing its function of weeding out inferior stocks. But they reluctantly admit that to revert to the use of natural selection destroys the characteristic work of civilization. It has taken centuries upon centuries, they contend, probably millions of them, for society to have made the civilized progress of our times. Man has aided with mutual forbearance in this civilization; consequently he cannot undo the structure without destroying himself. What man can do is to substitute for natural a rational selection.

Eugenists also hold that the perpetuation of inferior stocks can be prohibited simply by having "a rational conception of fitness and a knowledge of the loss of heredity." Improving the stock by rational selection is quite legitimate, it is thought. Once having been born the child has a right to live; its claim upon society cannot be ignored without destroying the principles of the humanized social order. The claim, however, to bring children into the world is another question.

Many eugenists do not possess true conception of man's *social* worth; many have not the faintest knowledge of the laws of inheritance, the two elements that are strictly necessary to have a competent understanding, not only of the eu, but of the genics. Some of the more careful of the eugenists honestly aver that a well-established social philosophy for a thorough application of their principle is needed; others believe that mere enactments of law are alone sufficient to bring about the superman and the superwoman. As to the causation of many of the highest human qualities little is known; they readily admit that, before passing sentence of condemnation on any stock which perhaps may possess good elements mixed with blemishes, care should be exercised. They say that we do not want insanity, nor feeble-mindedness, nor alcoholism, nor syphilis. These are evils *in se*. Those infected with these diseases should be prevented from bringing children into the world after their own likeness.

It will readily be admitted that humans contain blemishes which are not serious in themselves, but which are insufficient adequately to condemn a stock. Take the subject of tuberculosis. Volumes upon volumes have been written as to the cause of this terrible malady, but we do not know even to this day whether this disease is hereditary or not. Every physician knows that some splendid specimens of manhood and womanhood have been stricken down with tuberculosis, whose qualities were of the highest, and whose infection involved no mental or moral turpitude.

Now if the tuberculous tendencies were stamped out what other qualities are we not stamping out along with it? If an otherwise talented stock contains this blemish will there result in its disappearance a net loss or net gain? Who can say? Consider the rapid advancement society has made along these lines of social progress in the last one hundred years. Society has gone forward in leaps and bounds by the development of the arts and sciences, both of which have helped millions who without such aid would have perished. It might well be asked whether if the tubercle had been left to carry on its ravaging work unchecked would there have been any social progress at all? If we may succeed in eliminating the tubercle by the development of scientific hygiene instead of eliminating the tuberculous—unless correlated with some other irremediable disease, tuberculosis will no longer be considered a defect. If the marriage of members of such stock had been prohibited the population and all that they might have contributed to society's permanent gain would have been lost.

Society in seeking to eliminate the vicious should be cock sure that its removal would be a net gain to society. We must be certain that the vice so often complained of by eugenists is irremovable, that it is dependent on conditions which we can modify. It is an open question whether eugenists in their strange program of a superhumanity would not be violating traditions of civilization and creating tendencies to rebarbarize the race.

Let us consider the case of the feeble-minded. This class represents a type which can be identified with a certain amount of accuracy. If we should categorize this class we would include men and women whose existence depends chiefly upon the state or the bounty of relative or friends. These dependents lack capacity; they are "drifters," who usually find their way to some jail or workhouse,

and whose condition is said to be hereditary in a high degree.

Cases such as these eugenists may well press for social solution, whether it be physiological or medical. It is a commonly accepted fact of life that a man's position and relation to society depends upon his social worth. But even in the well-to-do class are the pauper characters, "drifters," who neither spin nor work, but simply live to dissipate their patrimony. Society at large never hears of the well-to-do pauper character. Some men are brought to the top of the world by sheer good luck. The qualities by which men get up in the world are admixtures of good, indifferent, and bad. As to the predominating force of these three elements, consideration must be given as to the character of the social organization.

In these times what proof have we of actual deterioration? No report that would serve as a basis for studying physical deterioration of the race has ever been undertaken, and until such a program has been started we had better not rush into print and lament over the decline of society. Some years ago a committee was organized in England to study the question of race deterioration. The committee was not biased, and all available evidence in favor of deterioration was given serious study. It was found that there was not sufficient material at hand to warrant any definite conclusion on the question of the physique of the people examined by comparison with data obtained in times past, yet says the committee "the impressions gathered from the great majority of witnesses examined do not support the belief that there is any general progressive physical deterioration."

If we take up the matter of insanity we shall have to consider the causes of the increase of the insane. It is a most difficult question to determine the real elements that cause the increase of lunacy. Whether we can interpret the increase as evidence of physical deterioration, especially in industrial centers, may it not be connected with density of population; may it not be rather an effect of the worst side of our social environment, the rush and crush and strain of our industrial life than of deterioration of stock?

Since we have no inductive evidence of race deterioration we can go on inquiring why natural selection should be suspended within the limits up to which this suspension is possible to lower the social standard.

Like most biologists, the eugenists cannot concentrate their activities along direct lines. A great many biologists believe that environment has no direct effect upon the development of stock. On this point they dogmatize. On the other hand, there are other schools of biologists who assume to speak to the contrary, but they make the mistake of not differentiating between *racial* and *social* progress. Not until sociologists come to understand the biological points of race and environment—nature and nurture—will they appreciate that there is a great difference between *racial* and *social* progress. It is a question whether all social legislation has not been based on the assumption that better environment meant race progress.

That the Malthusian principle has tended to lower the general rate of reproduction among the wealthy class is true. The eugenists are nobly serving society by calling attention to the dwindling of the family among this particular class. The wealthy cannot cry out and say it is wrong for them to bring children into the world for whom no provision in life could be made. But that economic conditions affect the birth rate in different classes is unworthy of disputation. The poorer class seem to care very little about economics as this question affects the birth of their children. They seem to believe true happiness can come only with a large number of offspring. They know little about biology, environment, nature, and nurture, racial and social progress, and care less. And they seem to be happy in their set lives. What a great social work eugenists could accomplish, what a boon they would give to their cause if they could eradicate from the minds of the wealthy, and even the great middle class who ape the rich in all things, the belief that the reproduction of children is a social burden which they are not called to shoulder.

Suppose that the inferior stocks are actually more prolific in breeding than the better ones, the question remains whether the effect on the *race* is as serious as some believe. If we consider the average of congenital endowment in the race, we should ask how far this will be affected by the greater fertility of inferior stocks. It is assumed by the older biological theorists that "the race progressed by the constant cutting off of the tail and the consequent shifting forward of the mean point of capacity." According to some anti-eugenists "racial progress depends, not on the summation of small fluctuations that are constantly arising and dying away again, but on more definite mutations which, once arising, give birth to a new stock with a new mean point of its own. The individual descendants of the new stock will exhibit qualities which fluctuate about the new mean, but which tend always to return to it. The fluctuations, even if they persist for a generation or two, are not permanently transmitted. They arise and die away again. The mutations, on the other hand, are of permanent significance."

Applying biological conceptions scientifically we know that large fluctuations may have the same exterior appearances as true mutations, but their effect will be very different in after generations. However, in scientific practices we should be able to particularize on classing the stock evidencing some bad qualities. It cannot be denied that the fundamental strains constituting a population are intricately interwoven; neither can it be denied that in individuals are certain variations that arise from the conditions due to breeding and germinal quality. Should not physicians and those who are displaying an ultra-interest in eugenics first turn their attention to psychological conditions resultant from the laws of blending to see whether these conditions would not be more important for serious study than physical genetics?

Before we can safely advance along the lines of social progress there is a vast amount of work to be done in the line of heredity; there is exploring to do; there is scientific research work. We have yet to come to an appreciable understanding, a point to which eugenists have not yet brought us, why roving and undisciplined characters—the vagrant class—show strains which when mated produce originality and genius; why persons evincing the gentler strains give rise to weaklings who have influenced the coarser material of their mates.

The strict application of eugenic ideas must await the progress of biological knowledge. Those who believe in and advocate every social panacea and legislative interference for the uplifting of the human race should remember that inherent vice can-

not be converted into innate virtue, nor can they change "leaden instincts into golden conduct," nor "transform a sow's ear into a silken purse" by any known social progress.

108 Essex Avenue.

## VENESECTION IN CEREBRAL HEMORRHAGE, WITH REPORT OF CASES.*

By ANDREW MacFARLANE, M.D.,

Albany, N. Y.

In our mad rush after medical novelties like women after a new style bonnet; in our oftentimes pathetic and almost hopeless search for curealls and specifics, it is a comfort to speak of a remedy which is not new and whose origin goes back beyond the ken of man, even to the age of mythology and prehistoric times. It has shared the lot of the animate as well as the inanimate. It has been proposed, become popular, been employed for every conceivable condition, and then has been abused and suffered obscurity on account of its indiscriminate popularity.

Venesection was in full use in the days of Hippocrates and was employed at the siege of Troy by a son of Aesculapius upon the warrior king, Menelaus. The Greeks, however, claim that Pedalirius, another son of Aesculapius, was the first to practice venesection among them. It is related that he cured Syrma by bleeding at a time when her life was despaired of because of a fall from the roof of a house. Hippocrates recognized three indications for blood-letting: First, as an evacuant; second, as a means of diverting the blood from a part predisposed to congestion, and, third, to relieve congestion. Themison, in 63 B. C., bled in apoplexy and even employed the trepan for the relief of the engorged blood vessels. Galen, in 131 A. D., strongly commended bleeding in apoplexy and syncope. Ambrose Paré obtained great relief from hemicrania in his own person as well as in patients by bleeding from the temporal arteries. During the eighteenth century the harmful results of the indiscriminate employment of bleeding became so evident that there raged in the profession and among the public a battle royal between the vehement adherents and the no less strenuous opponents of the practice. The latter dwelt with emphasis upon the serious complications which often ensued—ulceration of the tissues at the elbow, phlebitis, rupture of the biceps tendon, endocarditis, septicemia, and tetanus. The treatment of apoplexy was the subject about which this battle raged most fiercely. It was recognized even then, however, but not always with well defined clearness, that there was a form of apoplexy in which bleeding might not be indicated. "But in the severe cases of true apoplexy, the 'hemorrhagia cerebri' of the books, bleeding is demanded and unless the case be seen late it cannot be safely omitted."

In spite of its evident value in certain cases it passed into absolute neglect due largely to the influence of that master clinician Trousseau. In our day one fails to find anything more than its merest mention and our authoritative text books suggest the advisability of its employment with much questioning or with faint praise. Strumpell says: "Bleeding was formerly universally practiced, but of late its usefulness is doubted." Dieulafoy merely makes the pathetic statement: "Apoplexy is treated by bleeding, leeches behind the ears, enemata, purgatives, and counterirritation of the lower extremities." Osler recommends venesection, and then condemns it by quoting Cushing's experiment on intracranial blood pressure. Spiller, in Musser and Kelly's "Practical Treatment," says: "When the pulse is very full, 8 to 16 ounces of blood may be removed. It is questionable whether such bleeding is of benefit to the patient." Grinker, in Forchheimer's "Therapeusis of Internal Diseases," says (in small type): "In plethoric and robust individuals venesection is indicated. On several occasions I have seen beneficial results from the withdrawal of large quantities of blood in comatose patients. In many cases no good is accomplished by this measure. Bleeding seems to do good in the milder cases only." On the other hand, Tyson, in the last edition of his "Practice," states with emphasis that the patient should be bled at once unless the pulse is small and feeble. Tooth, in Allbut's "System of Medicine," says that "bleeding in cerebral hemorrhage has passed through a long period of disrepute, brought about by its indiscriminate use. It is doubtful whether its discontinuance as a mode of treatment is not almost as discreditable as its abuse. On physiological grounds it is difficult to see that it can do anything but good when used with discrimination."

In apoplexy there is a hemorrhage usually from a branch of the artery of the fissure of Sylvius. The blood escapes under a pressure nearly equal to the general arterial pressure and subjects the adjacent soft substance of the brain to the possibility of destruction by this pressure which is transmitted in every direction. The vital indication is to promote coagulation at the point of rupture and thus stop the hemorrhage and minimize the pressure upon and thereby the destruction of the soft tissue. Coagulation of the blood, according to the theory of Howell, is due to the action of the enzyme thrombin. This arises from the cells, the intima and the leucocytes, and when liberated by rupture of the intima splits up fibrinogen into fibrin. This destroys the balance normally present between antithrombin, which possibly comes from the liver and thrombin. The vascular pressure plays an important but secondary part in the stability of the clot. It is very doubtful whether we can increase the coagulability of the blood in a way to be of service in apoplexy. Horse serum is certainly a valuable hemostatic in many cases of vascular hemorrhage, and Wright has advised the use of calcium salts to hasten coagulation, but personally I have seen no mention of the value of either in cerebral hemorrhage.

It is, however, within our power to modify the vascular pressure. Two means are at our disposal: 1. Horsley and Spencer have shown by experiment that hemorrhage from the middle cerebral and its branches may be controlled for a considerable time by compression or ligature of the carotid on the same side and this in spite of the anastomosis of the circle of Willis. 2. Venesection or arteriotomy of the temporal artery. Both tend to lower arterial pressure and, even though temporarily, lessen the hemorrhagic effusion and allow coagulation to take place. Of all the drugs employed for the reduction of blood pressure it is more than doubtful if any one of them has much more than a suggestive effect and that almost entirely on the physician himself. In a full-blooded patient with face flushed and pulse full, bounding, somewhat slow and of high tension (200 mm.), venesection will immedi-

*Read by invitation at the seventh annual meeting of the Fourth District Branch of the Medical Society of the State of New York, at Fort Edward, N. Y., Oct. 14, 1913.

ately reduce the tension, if only temporarily, fifty or more millimeters, thus aiding the organism to firmly fix the clot. What else have we to offer? An ice cap to the head, hot applications to the feet, croton oil on the tongue and nitroglycerin or its congeners.

Truly pathetic is this inactivity when immediate masterful activity is demanded to save the patient from a fate often worse than death. Two criticisms seem possible. That of diagnosis and, second, the ability to do this simple operative procedure. The diagnosis in the vast majority of the cases is evident after a superficial examination. In fact, the laity usually make the diagnosis. They appreciate the gravity of the condition and send for the physician at once at the most opportune time to help. But even if the diagnosis is obscure the indication is no less insistent. This treatment is purely symptomatic and is indicated only when abnormally high blood pressure is present. Although I appreciate that our interpretation of blood pressure is as yet in its infancy and that many of our present theories regarding the same may in the future be much modified or even discarded, still I believe it is a fact beyond dispute that any patient suddenly becoming unconscious or presenting symptoms of cerebral insult with a blood pressure of more than 200 mm. should be immediately bled. With the common use and ease of employment of the various sphygmomonometers and the certainty thereby of the accurate determination of the blood pressure the merest tyro is able to recognize with absolute exactitude this indication. The act of venesection itself has assumed an unnatural formidableness to those of us who are not surgeons because it is not in common practice. In the unusually stout person there may be some difficulty in finding easily a vein at the bend of the elbow, but in these patients there are usually in the legs varicose veins which stand out imploring to be relieved. There is no need of speaking of the complications common a century ago. Today there should be none to the physician who uses even ordinary care. The following cases are illustrative:

Case I.—W. J. H., male, aged 44, married, and has one child. Office work. Weighs stripped 260 pounds. Seen in consultation. Has smoked excessively—20 heavy cigars a day. Drank freely up to two years ago and since then moderately. A hearty eater. Denies venereal history. Thirty-five years ago had a mild fever lasting two weeks and three years ago had neuritis affecting his left arm after a fall. His father died from tuberculosis at 58. Mother found dead in bed, probably apoplexy, when 64. One sister aged 54 in good health. On July 4, 1913, he returned home, having traveled the previous night in a sleeping car with window open and exposed to the draught. As he attempted to leave the train at 8:30 a. m. he noticed his left leg seemed heavy and he had a little difficulty in walking. Later his left arm appeared awkward and by noon both the arm and leg were moved with difficulty; the tongue was protruded to the left and the mouth was slightly drawn to the right side. Pupils equal and reacted normally. Reflexes active. Urine free from albumin and sugar. Heart and lungs negative. Pulse full, bounding, 110 in frequency and blood pressure was 235 mm. Temperature normal. Twelve ounces of blood were removed from a vein in the right arm. The following day the improvement was so marked that the patient urged the removal of more blood when one and a half pints were drawn from a varicose vein in the patient's leg. On July 6, 10 ounces more of blood were removed. His blood pressure dropped to 180 mm. then very gradually went up to 200 mm. He was placed on a light diet, largely buttermilk and salines. July 28th he was able to walk about the house without assistance and felt in excellent spirits. His weight is now 225½ pounds, a loss of 35 pounds and the blood pressure is 180. He walks out with a slight hitch and exercises to a point of fatigue. Sleeps well. His diet now consists of milk, buttermilk, all kinds of green vegetables, fruits, eggs and fish.

Case II.—Mrs. H. B., a widow, aged 54, was admitted August 1, 1913, to St. Peter's Hospital, Albany, in profound apoplectic coma. Seen in consultation with Dr. Fromm The family history was essentially negative. Up to within two years of her admission she had always enjoyed good health. During the past two years the patient suffered two seizures, one of which was pronounced by her family physician to be uremic and the other a very slight cerebral hemorrhage. She recovered from the latter with no paralysis. Her present illness was of two days' duration and occurred at a summer resort not far from Albany; in the middle of the afternoon of July 29 while at table she complained of a numb feeling in the left arm. She was taken to her room, put to bed and in an hour became unconscious. The patient, a large framed plethoric woman of the German type, was in deep coma with stertorous breathing. The left arm and leg presented marked rigidity; there was no inequality of the pupils. The lungs and heart were negative with the exception of a moderate accentuation of the second aortic sound. The radial and temporal arteries were slightly sclerotic. The urine with a specific gravity of 1005 showed the presence of a large amount of albumin and a few hyaline and finely granular casts. The systolic blood pressure by the "Tycos" instrument was over 260. Venesection was now resorted to and 12 ounces of blood abstracted from the right median basilic vein. One hour later the systolic pressure was 185. The next day the rigidity of the left arm and leg gave way to a well-marked flaccid hemiplegia accompanied by a ptosis of the left eyelid and a dilation of the corresponding pupil. The systolic pressure was 195. There was no amelioration however in the comatose condition. On August 3rd the systolic pressure was 170 and two days after admission without regaining consciousness the patient died. The severe hemorrhage from which this patient apparently suffered precluded hope from any line of treatment.

Case III.—Mrs. F. B., 65, widow, was brought to St. Peter's Hospital, Albany, September 7, 1913, in the ambulance unconscious and with no control of bowel or bladder. Her family history is not significant. Father, one brother, and one sister died of pneumonia; another sister, from heart trouble, and a brother from cancer of the stomach. Her mother died from puerperal fever at 28, and one sister is living and well. She had scarlet fever at eighteen which was followed by some cardiac disturbance. She has had no children and no miscarriages. She drinks two cups of strong coffee each morning and two cups of tea for dinner and for supper. She has never used alcohol in any form or drugs of any kind. She was unconscious on entrance with frothing from the mouth. The mouth was drawn slightly to the right side and there was apparent rigidity of the entire right side. Eyes were normal but the patella reflexes were absent. The heart and lungs were negative and the urine contained a large quantity of albumin but no casts were found. The blood pressure was 260 mm. Venesection was done at once and the pressure fell to 175 mm. She remained unconscious for 24 hours and then was very dull and apathetic. No hemiplegia was present. The pressure gradually rose and three days later reached 240 mm. On Sept. 26 she was out of bed and about the ward though still somewhat dazed and uncertain in her movements. She was discharged improved from the hospital October 1, 1913.

This is apparently a case of cerebral congestion without vascular rupture, but the indication for venesection was equally marked.

Case IV.—D. W. C., aged 70. An active, wiry man. Seen in consultation with Dr. John J. Beard, September 20, 1905. While attending the Fulton County Fair the patient noticed a weakness of one side which rapidly developed into a hemiplegia. The median basilic vein was opened and a quart and a pint of blood were removed. The paralytic symptoms rapidly improved and in about three weeks the patient was out and about with only a slight limp and weakness of his hand. He lived actively for a number of years after this attack.

**Permanent Alopecia Following X-ray Treatment for Tinea Tonsurans.**—G. Pernet reports the case of a little girl who had been *x*-rayed two years previously. There was complete alopecia. As there were a few small crusted lesions the author ordered a diluted white precipitate ointment, and the mother was sure some of the hairs had grown since. A few stray hairs were now to be seen.—*Proceedings of the Royal Society of Medicine.*

## A PRELIMINARY REPORT UPON THE SPECIFIC ACTION OF ETHYL HYDROCUPREIN ON PNEUMOCOCCUS INFECTION OF THE EXTERNAL TISSUES OF THE EYE.

BY ALFRED WIENER, M.D.,

NEW YORK.

AN ulcus serpens upon the cornea of an eye is a very serious affection. It is so malignant in its nature that partial or complete blindness is the usual outcome. If the eye escapes destruction, the poor vision which remains is due to the dense corneal opacity which follows the healing of the ulcer. Even in the mildest cases the sight is interfered with to such an extent that an iridectomy is often necessary to obtain fairly serviceable vision. In the *Klin. Monatsblätter f. Augenheilkunde* there appeared in the October and November numbers of this year two articles which called attention to the excellent results obtained by the use of ethyl hydrocuprein, a derivative of quinine. Morgenroth and his associates had proven that the chemotherapeutic influence which this preparation has upon the pneumococcus, the germ responsible for such a malignant ulcer, is practically specific. M. Goldschmidt, working in the clinic of Prof. Dr. H. Sattler in Leipzig, and Max Schur in the clinic of Prof. Dr. G. V. Schleich in Tübingen, have made use of this chemical clinically and reported their results in the above-named journal. They were so convincing and so astonishing that I was persuaded to make use of this preparation in a case which recently came under my observation.

M. K., 45 years old. A sufferer from dacryocystitis for a great many years, developed about three days previous to the time that I first saw him an ulcer of this nature. He was attacked with sudden pain and redness of the right eye. On the following day he noticed, as he expresses it, a white spot over the pupil. The pain became intense. There was marked photophobia and epiphora. His vision was very much interfered with. I saw him on the third day, and his status was as follows: Right eye showed a central ulcer of the cornea. There was present intense epibulbar and ciliary injection with conjunctivitis. On the conjunctiva, and from the sac, one could express a mucopurulent secretion, more purulent than mucus. The ulcer appeared progressive towards the inner and lower part of the cornea, sloughy on its surface, and an infiltration deep into the parenchyma. The cornea was hazy throughout, and there was a distinct hypopyon. Vision equal to hand movements. The patient was admitted to St. Luke's Hospital. He was placed at once under the treatment as prescribed by Goldschmidt and Schur. The ulcer was bathed with a 1 per cent. solution of ethyl hydrocuprein for one-half minute every hour. This was done for six hours on the first day, and twelve hours on the next. Just previous to using the drops the sac was expressed, and the conjunctiva thoroughly cleansed with boric acid. On the morning of the second day the hypopyon had vanished, and the cornea, with the exception of a minute spot on the surface of the ulcer, was transparent. The edges of the ulcer were clean, and no progression noticeable in the parenchyma. On the third day, with the exception of a slight depression and faint macula in the region of the ulcer, the cornea was practically normal in appearance. The bulbar and palpebral conjunctiva still showed some injection, and a mucopurulent secretion could still be expressed from the sac. This secretion, however, was different in nature from that found early in the disease. There was now more mucus than pus. A culture still showed the pneumococcus. On the seventh day the sac was removed. The eye is now practically well and the culture is sterile.

I have only this one case to report, but its threatening and treacherous outlook was so evident, its response to the treatment after eighteen hours so astonishing that I felt the result should be recorded. It is for this reason that I report it as well as with the hope that others will make use of this chemical preparation, and place their results upon record, so that we may come to some definite conclusions in regard to its value.

**Massive Coagulations of the Cerebrospinal Fluid.**—R. Debré and J. Paraf allude to the rarity of this condition, twenty instances of which have been reported. They report the case of a girl aged 14 years suffering from tuberculous meningitis. The cerebrospinal fluid removed by lumbar puncture completely clotted in a few minutes. The authors point out that in the majority of cases in which the cerebrospinal fluid behaves in this manner, the patients present the symptoms of meningomyelitis or of spinal compression with paraplegia.—*La Presse Médicale.*

**Splenic Enlargement, Hemorrhage, Anemia, with Oral Sepsis.**—W. Essex Wynter reports the case of a man aged 50 who had severe epistaxis in May, 1913. He went to the hospital and the teeth were attended to after the bleeding had been stoppd. On August 10 there was sudden pain below the left ribs; the spleen was found enlarged, and when the patient was admitted to the hospital on August 20 it extended to within 1½ inches of Poupart's ligament, and 2 inches beyond the umbilicus in the middle line. It was firm and not then tender. The heart and lungs were normal. On September 10 sudden and severe pain occurred over the spleen, with subnormal temperature, vomiting, and collapse. Friction could be heard over the organ, which was apparently the seat of an infarct. A similar attack occurred two days later, but less severe, and no friction could be detected. On September 18 severe and persistent epistaxis occurred, which was only arrested by plugging the nostril. On September 25 this recurred with less severity, both attacks being preceded by severe headache. No lesion of the mucous membrane could be detected. Apart from the leucocyte count the picture was that of splenic leukemia. The urine contained 0.3 per cent. of albumin, but was otherwise normal; specific gravity 1020; it was acid and clear; albumoses were not found. The teeth were much decayed, have been entirely neglected, and there was extensive pyorrhea.—*Proceedings of the Royal Society of Medicine.*

**Actinomycosis of the Cheek Treated by Parenchymatous Injections of Formalin.**—G. H. Makins reports the case of a boy, aged 17, who was admitted into St. Thomas' Hospital in January, 1913. Two months previously an alveolar abscess had developed in connection with some carious teeth. The abscess was incised, and shortly afterward a hard, brawny swelling developed in the right cheek. On admission this swelling occupied an area of about the size of a half-crown piece. It was bluish red in color, very hard, and firmly fixed to the surface of the maxilla. Four discharging sinuses were present, and on examination of the pus exuding from these the streptothrix of actinomycosis was discovered. During the month of February iodide of potassium, beginning with 5 grain doses, rapidly increased to 20 grains, was administered internally three times daily. On February 21 two hypodermic syringefuls of 4 per cent. formalin solution were injected around the periphery of the indurated area and into the margins of the area itself. The injection was followed by considerable swelling of the cheek and lower eyelid. A second injection was made on April 4, after which all the sinuses closed. Meanwhile considerable diminution occurred in the extent of the induration. Further injections were made on April 22, May 30 and July 16. Each injection was followed by considerable local edema which rapidly subsided, after which the indurated tissue became less in extent and freely movable upon the maxilla. The injections were necessarily made around the circumference, since the fluid could not be freely forced into the indurated area. At the present time the cheek is nearly normal, the only fixed spot corresponding with the cicatrix of the largest of the sinuses present when the formalin treatment was commenced.—*Proceedings of the Royal Society of Medicine.*

## THE NATURE OF OLD AGE AND OF CANCER.

THE conception is not new which regards cancer as in some way allied to senile changes in the tissues. Yet probably no hypothesis has yet been advanced which so ingeniously coordinates the phenomena of both old age and cancer as does that put forward by Hastings Gilford in the *British Medical Journal*, December 27, 1913. He points out that one feature of cancer which suggests a developmental origin is the variability in its rate of growth. In this variability, however, there may frequently be perceived an acceleration and a retardation suggestive of the rhythmical or cyclical changes of normal development. That which points most conclusively to a developmental origin of cancer is the fact that this process originates in cells whose development has been arrested. The secret of cancer, according to Gilford, is to be sought in the proper conception of the declining period of life. The involution of the organism must be regarded as a necessary phase of development, which may be graphically represented by a curve that reaches its summit in middle age and then descends to terminate in death.

What is the essential nature of senility? This is not merely disorganization and decay, but is an orderly biological phenomenon that is shown in each of three ways, namely, in decay, in fibrosis, and in proliferation. In the process of decay the higher types of cells are stricken first, and each organ seems to have its own standard of longevity. The process of fibrosis is intimately associated with that of decay. The effete materials resulting from the senile deterioration of the cells are taken up by the fixed connective tissue cells, which undergo proliferation in order more effectually to perform this function. These connective tissue phagocytes when they have fulfilled their rôle, settle down as inert fibrous tissues. This conception of the fibrosis incident to old age is based upon Metchnikoff's observations. Gilford, however, emphasizes the fact that neither decay nor fibrosis is the essential factor in senility. Each of these changes is merely the expression of the fundamental phenomenon of old age, namely, regression.

Between the higher type of cells which exhibit most prominently the changes incident to senile decay and the lower type, such as the connective tissues cells which serve a mechanical purpose or act as phagocytes, there is a type of cells that display a combination of the properties of the above two groups. The last type consists of the epithelial cells whose growth does not cease with old age. There is a tendency for epithelial structures to undergo proliferation during old age. As examples may be mentioned the development of corns and callosities, the renewed activity of the mammary gland at the menopause and the overgrowth of the renal epithelium in old age.

Gilford applies the conception which regards senility as a condition whose dominant note is one of regression, in the interpretation of cancer. This he attributes to the same fundamental process. "Certain somatic cells become aged while the tissues around them are still in a state of comparative youth. They express their senility by returning to a more embryonic form, and as they do so they increase in number, the faculty of multiplication being one of the manifestations of regression." Cancer cells are derived from the lower type of cells whose senility is characterized not by decay but by proliferation. The cells that give rise to cancer are in a state of suspended development or infantilism, and just as human beings who are in a condition of infantilism are prone to premature senile decay, so also the infantile group of cells take on early the senile tendency, which in the case of these cells is one of lawless proliferation.

The question now arises, how can one account for the suspended development or infantile condition of the cells that give rise to cancer? The answer is that this suspended development is but an instance of the fluctuations to which all living things are subject. The latent or normal fluctuation of a certain group of cells may be intensified or exaggerated by some external irritation, such as the friction of a rough surface. As a result the cells which lag behind in their development and behave as embryonic residues, are stirred into a senile proliferative activity. In this capacity they become alien to their environment, giving rise to the reactive proliferation of the surrounding connective tissue elements and to other secondary changes.

The essence of Gilford's theory of cancer is the conception of premature local senescence or cell senilism.

## SUCCESSFUL REMOVAL OF AN EMBOLUS FROM THE ABDOMINAL AORTA.

THE lodgment of an embolus in the abdominal aorta is a rare occurrence; but the successful removal of such an embolus, as reported by Fritz Bauer (*Zentralblatt für Chirurgie*, Dec. 20, 1913) is so much more of a rarity that it deserves special mention. At the beginning of last September, a man, 39 years old, suffering for 16 years with articular rheumatism, entered the medical side of the General Hospital at Malmö, Sweden, the diagnosis on admission being insufficiency and stenosis of the mitral valve. Not long after admission the patient was suddenly seized with severe pains in both legs, especially the left, and found that he was unable to move them. At the same time he noticed that they were blue and cold. Dr. Brahme was summoned and after making a diagnosis of embolus in the aorta, no-

tified the surgical division and had the patient transferred there. Examination showed severe pains in both legs and upward to the abdomen, the skin on both legs and on the abdomen up as far as the navel was livid, marbled, cold, a little more on the left side and in the peripheral parts; no pulse was palpable in the lower extremities; there was complete loss of sensation in the feet and lower legs, not complete in the thighs or in the lower part of the abdomen; inability to move the legs; abdomen not distended; no edema; no ascites.

There was no doubt that an embolus caused these symptoms, and that most probably it was lodged firmly in the abdominal aorta just above its division, since there were no symptoms pointing to any acute disturbance of the abdominal organs or the kidneys. It was further clear that the threatening gangrene in both legs made necessary the removal of the embolus as soon as possible. About three hours after the beginning of the attack an incision some 20 cm. long was made in the linea alba, and another incision in the posterior peritoneum to the left of the root of the mesentery laid bare the aorta and iliac arteries to the extent of about 10 cm. The pulse could be felt in the aorta to about 3 cm. above the point of its division, but there was no pulsation below that. Just below the point of pulsation one felt a firm mass which extended a little way down both iliac arteries. Under digital compression of the aorta by an assistant, an incision about 2 cm. long was made lengthwise over the embolus which immediately came into view and was easily removed. The wound in the artery was closed by means of four No. 0 twisted silk sutures and between these, two Carrel sutures. The bleeding stopped after short, light compression over the sutures; both iliac arteries then pulsated. The extracted mass was 3 cm. long and shaped like a great tooth with two short roots; the crown in the aorta, the roots in the two iliacs. It had a nucleus about the size of a small hazelnut, yellow-gray, fairly firm, as the embolus proper; around this, a red mass of clotted blood. The patient made a perfect recovery.

Key successfully operated for thrombosis of the femoral (*Hygiea*, lxxv, 1913), and found three cases of operation for embolus of the peripheral arteries in the literature; one successful and two failures. Willy Meyer (Trans. Am. Surg. Asso., Vol. XXXI, 1913) states that in Trendelenburg's clinic twelve operations have been done for pulmonary embolism, and four in Sauerbruch's clinic, all the cases terminating fatally. These quotations refer to work in the other large vessels under somewhat different conditions and different degrees of difficulty; but, nevertheless, make Bauer's brilliant result appear all the more remarkable. We have found no other report of removal of an embolus from the aorta in current surgical literature.

## PUBLICITY.

Food is good for man unless it happens to disagree with him, in which case the resulting indigestion causes him a certain amount of discomfort and may do him actual harm. Publicity is likewise a good thing, but if the matter made public is beyond the ability of the readers to digest it, it can produce an almost incalculable amount of damage. One of the chief advocates among the daily press of publicity for medical reports, in discussing the recent and still active controversy about radium, divides the opponents of such publicity into three groups: (1) those who have been passed over by the reporters and are opposing because of envy; (2) those who have not had opportunities of working with the methods in question and are resentful of the publicity accruing to those with greater advantages; (3) those doctors who are annoyed when their patients are initiated into any of the preciously guarded medical "mysteries." Of course there is no doubt that these three classes of individuals exist and it may be that some of the noise in opposition to this publicity has arisen from among their ranks. The article in question, however, completely ignores the existence of a large class of thinking physicians who deplore the premature and incomplete presentation of a few experimental results to a heterogeneous mass of readers, the great majority of whom are wholly incapable of giving to them their true worth or of assimilating them without serious mental indigestion. One can easily call to mind the numerous cures of various kinds that have been heralded in the public press within the past few years. Eosin-selenium shows a pronounced effect upon certain mouse tumors and the public is told that cancer is no longer to be dreaded. The whole vogue of the Friedmann vaccine for tuberculosis was a product of newspaper publicity methods, and at the present time radium is being held up as the only sure hope of the cancerous. As a result of these immature outbursts of hysterical enthusiasm it has fallen to the lot of almost every physician to interview some patient suffering with incurable cancer or tuberculosis, to listen to the confident expression of a belief that here at last has been found a cure for his disease, and then as gently as possible to tell him that the confidence is founded on nothing more substantial than reportorial imagination. The patient is not justly to be blamed if he goes away cursing his doctor as a hide-bound conservative. We never love the man who destroys the bubbles of our fancy with the hot wire of fact. The responsibility for raising these false hopes rests directly upon the press which so eagerly disseminates this variety of partial information. After a veritable orgy of ill-considered enthusiasm, the cold facts concerning radium are beginning to filter into the public press and the public is at last being told that, while this wonderful element has its own place in the treatment of cancer, this place is distinctly limited and it cannot be relied upon to cure every case. How much wiser it would have been to have started the discussion with this premise.

In this same article this paper claims that it "can truthfully assert that it has promulgated no sensational or harmful statements." In another column of the same issue is an article entitled, "The Artificial Kidney," which is based on an article by Abel, Rowntree, and Turner (*Jour. Pharmacol. and Experiment. Therap.*, 1914, V, 275), in which they

report their experiments on the removal of substances by dialysis from the circulating blood of living animals. Nowhere in their report do these authors intimate that the apparatus in question offers a cure for nephritis or could be substituted for a diseased kidney. Yet this newspaper says "an 'artificial kidney' has been invented . . . . to do the work which the kidneys refuse to do, as also the work for which they may be incapacitated from doing." And later, "As a substitute for the work of the kidneys in an emergency and to tide over dangerous crises, this 'artificial kidney' should be available and useful in the hands of skilled surgeons." It is almost certain that as a result of this article many surgeons will be importuned to save the lives of patients in uremic coma by making an artificial kidney, and it will be difficult for them to convince the relatives that such a thing is impossible. Again hopes will be raised only to be crushed, and doubtless the newspaper will disclaim responsibility. It is, of course, not to be expected that a few hours' rest such as would be afforded by the use of this apparatus would enable a badly diseased kidney to resume functioning, but many readers who lack special knowledge will be unable to appreciate this fact. It is just this sort of ill-advised publicity to which the thinking members of the medical profession are strongly opposed and which has turned many physicians against what was at one time the newspaper of their preference.

### The Alleged Epidemic of Syphilis in Europe Following the Discovery of the Antilles.

Sudhoff, one of the few great medical historiographers of the school which look always into original sources and collateral sources, announces that after many years of research he is quite unable to verify the tradition regarding a general venereal pestilence in Europe after the discovery of America, and supposedly brought from that continent. Many years ago F. A. Simon reached the same conclusion, but under very different conditions. Simon took such data as came to him and analyzed them vigorously. Sudhoff and his congeners, on the contrary, are recreating the past with all the thoroughness of one who makes an ordnance map. Hence at times they may not be at work on a medical problem, but on something which will eventually throw light on the latter. There was no venereal plague in Charles VIII's army in the spring of 1495; nor did such a one break out later in Charles' army of occupation. The pest which did "annihilate" his army at this time was beyond doubt typhus. No venereal plague proceeded from Italy to Germany and elsewhere. Syphilis was known in Germany as early as in Italy—perhaps earlier. The author has studied hundreds of files of archives of European cities from which alone could we expect to find traces of a new pestilence. In these we find mention of vagabonds cared for, among them syphilitics, but none migrants. The amounts appropriated for these diseased outcasts were very small, far too small to control any pestilent disease. The author devoted much time to Augsburg, one of the large medieval cities of Europe. In November, 1494, the first evidence is seen in the purchase of a house which soon became known as the Blatterhaus-Syphilis House. Complete records exist of this hospital from 1497 to 1550, including cost per year of maintenance, which is plotted into a curve. The figures are very low but occasionally shoot up, indicating that during that year some severe pestilence, as typhus or plague, increased the appropriation, but the low figures prevalent from 1497 to 1520 show that no pestilence of any sort was present. The one exception, 1511-12, was a bubonic plague year. Thus Sudhoff (*Münchener medizinische Wochenschrift*, December 9) seems to have proved indirectly that no great venereal plague ever reached Augsburg, but instead only a certain small number of local paupers required asylum treatment for the malady.

### Left-Handedness.

At a recent society meeting in Germany, Bardeleben (*Münchener medizinische Wochenschrift*, December 2) discussed the anomaly of left-handedness from the viewpoint of its relationship to mental and bodily inferiority. That a few great men were left-handed, such as Leonardo da Vinci, does not neutralize the prevalent belief—in all ages—that left-handedness implies a substandard subject. The percentage of left-handed recruits is but 6.8; of school children somewhat higher. These figures are very deceptive, however, for of the left-handed who became right-handed, the percentage is some 26. This, added to the persistently left-handed, raises the original percentage of left-handed considerably. This left-handedness may be shown to be left-sidedness, the entire side of the body showing evidence of a greater development on that side. In the brutes the preponderance of one or the other half of the body may vary according to race. Thus the gibbon and orangoutang are as a rule right-handed; the gorilla and chimpanzee left-handed. In brief, there is no evidence at all that a left-handed or left-sided subject is physically or mentally inferior. Left-handedness appears to be familial or racial. It is the predominance of right-handedness that requires explanation.

## News of the Week.

**Infant Mortality in 1913.**—The Babies' Welfare Association in its annual report places the death rate among infants in New York City during 1913 at 102 per thousand births, which is probably the lowest of any large city in this country. The total number of deaths during the year of children under one year of age was 13,779, as against 14.259 in 1912. The decrease in the number of deaths took place in Manhattan, the Bronx, and Brooklyn, while in Queens and Richmond, where but little infant welfare work was carried on, there were slight increases. The birth rate during the year dropped also from 26.22 per thousand in 1912 to 25.15 in 1913, the actual number of births being 135,655 and 135,134 in the respective years.

**Typhus on Steamship.**—On January 7, for the first time in at least twenty years, a case of typhus fever was brought into the port of New York, coming on the steamship *Roma* from Marseilles. The disease developed in the steerage during the voyage and was first discovered when the *Roma* arrived at Providence, to which port almost all of her passengers were bound. After being held in quarantine at Providence for a short time the ship was sent on to New York, by ar-

rangement between Surgeon-General Blue and Health Officer O'Connell, because of the inadequate quarantine facilities at Providence. On its arrival here one passenger suffering with the disease was transferred to Swinburne Island and thirty suspects were sent to the new hospital on Hoffman Island for observation. One death occurred on the ship during the voyage, but the disease was not then recognized and the diagnosis of tuberculous meningitis was made.

**Beriberi in New Jersey.**—A report from Surgeon-General Blue of the Public Health Service shows that during the last three years there have occurred in the county jail at Elizabeth, N. J., twenty-two cases of beriberi. The investigation showed that at one time all of the inmates of the jail who were serving sentences of over sixty days had contracted the disease.

**Pasteur Treatment by the Department of Health.**—The administration of the Pasteur treatment for rabies, which until January 1, 1914, was carried on at the Research Laboratory of the Department of Health of New York and at the Brooklyn Borough Office, was on that date transferred to the Bureau of Infectious Diseases, and a daily clinic from 1 to 4 p. m. was established in Room 802 on the eighth floor of the Department Headquarters, 149 Centre street, New York. On Sundays and holidays, patients from Manhattan are referred to the Brooklyn Clinic, held at the Brooklyn Borough Office, Flatbush avenue and Willoughby street, between the hours of 10 and 12 A.M. A clinic will also be established in the near future at the Bronx Borough Office. For the present cases from the Borough of Queens are referred to the Brooklyn Clinic, and cases from the Borough of Richmond to the Manhattan Clinic for treatment.

**Investigation of Lourdes.**—The Medical Society of Upper Bavaria, Germany, at a meeting on January 8, adopted a resolution requesting the Bavarian Government to investigate the propaganda of the Lourdes pilgrimages and the "exaggerated and misleading reports of alleged cures there."

**City Death Rate.**—For the week ending January 6 the death rate in New York City was 14.43 per thousand of population, the total number of deaths being 1,544, as against a rate of 14.75 and a total of 1,519 deaths for the same week of 1913. The deaths from measles, scarlet fever, influenza, and lobar and bronchopneumonia were considerably decreased, while those from diphtheria and croup, Bright's disease, pulmonary tuberculosis, and nephritis were increased.

**Harvey Society.**—Prof. Victor C. Vaughan of the University of Michigan will lecture before the Harvey Society at the New York Academy of Medicine, on the evening of January 17, at 8.30. Prof. Vaughan will speak on the "Phenomena of the Infection." On the evening of January 24 Prof. Sven G. Hedin of the University of Upsala will lecture before the society on "Colloidal Reactions and Their Relations to Biology."

**Tuberculosis Hospital.**—The Camden County Hospital for the care and treatment of persons suffering from tuberculosis, which is situated at Ancora, N. J., has just been opened. The hospital, which has been erected at a cost of about $50,000, is a frame structure, 368 feet long, 25 feet wide, and three stories high. It consists of an administration building which is connected by corridors with two wings, each 92 feet long and surrounded on both floors by spacious porches for outdoor treatment. There are four public and four private wards.

**College and Hospital.**—Under an agreement between the trustees of Western Reserve University and the Department of Public Welfare of Cleveland, O., the university secures the right of appointment of the medical and surgical staffs of the Cleveland City Hospital, and the sole privilege of using the patients for purposes of instruction and medical research. This will give the School of Medicine of the university the control of a hospital of 1,300 beds and will be greatly to the advantage of both institutions. The appointments which will be made by the Department of Public Welfare on the nomination of the university trustees will go into effect on February 1, 1914.

**Gifts to Charities.**—By the will of the late Mrs. R. S. Blumenthal of New York the Montefiore Home for Chronic Invalids receives $3,000 and Mount Sinai Hospital $300.

By the will of the late Annie Grandon of Philadelphia the sum of $5,000 is bequeathed to St. Joseph's Hospital and the sum of $3,000 to St. Vincent's Home and Maternity Hospital.

The Jefferson Medical College, Philadelphia, has received from Mrs. Lucy Henderson of New Castle, Pa., a fund yielding an income of about $2,500 annually which is to be used for the investigation of the effect of radium upon cancer.

**Personals.**—Dr. W. W. Keen of Philadelphia was recently re-elected president of the American Philosophical Society.

Dr. Wallace R. Hunter of Erie, Pa., has been appointed by Governor Tener as a member of the commission to select a site for the State institution for inebriates.

Dr. Edward Osgood Otis of Boston has recently, after twenty-seven years of service, announced his retirement as senior physician of the Boston Dispensary. He will remain on the staff as a consulting physician.

**Medical Society Elections.**—SOUTHERN SURGICAL AND GYNECOLOGICAL ASSOCIATION: Twenty-sixth annual meeting at Atlanta, Ga., on December 16 to 18. Officers elected: *President,* Dr. John Wesley Long, Greensboro, N. C.; *Vice-Presidents,* Dr. Arthur Carroll Scott, Temple, Tex., and Dr. James F. Mithell, Washington; *Secretary,* Dr. W. D. Haggard, Nashville, Tenn.; *Treasurer,* Dr. Le Grand Guerry, Columbia, S. C. The next meeting will be held in Asheville, N. C.

ST. JOSEPH-BUCHANAN-ANDREW COUNTY (MO.) MEDICAL SOCIETY: Annual meeting at St. Joseph on December 3. Officers elected: *President,* Dr. J. J. Bansbach; *Vice-Presidents,* Dr. F. H. Spencer and Dr. F. H. Ladd; *Secretary,* Dr. W. F. Goetz; *Treasurer,* Dr. J. M. Bell.

SUMMIT COUNTY (O.) MEDICAL SOCIETY: Annual meeting at Akron on December 2. Officers elected: *President,* Dr. David H. Morgan, Akron; *Vice-President,* Dr. Thomas K. Moore, Akron; *Secretary,* Dr. A. S. McCormick, Akron; *Treasurer,* Dr. S. J. Metzger.

MIAMI COUNTY (O.) MEDICAL SOCIETY: Annual meeting at Piqua on December 4. Officers elected: *President,* Dr. J. E. Murray, Piqua; *Vice-President,* Dr. J. R. Eichelberger, Fletcher; *Secretary-Treasurer,* Dr. R. H. Spencer, Piqua.

GREENWOOD COUNTY (S. C.) MEDICAL ASSOCIA-

TION: Annual meeting at Greenwood on December 4. Officers elected: *President,* Dr. J. S. Fooshe, Ninety-Six; *Vice-President,* Dr. J. D. Harrison, Greenwood; *Secretary-Treasurer,* Dr. J. F. Simmons, Greenwood.

MAURY COUNTY (TENN.) MEDICAL SOCIETY: Annual meeting at Columbia on December 1. Officers elected: *President,* Dr. O. J. Porter; *Vice-presidents,* Dr. E. M. Ragsdale and Dr. P. H. Faucett; *Secretary-Treasurer,* Dr. P. D. Biddle.

JEFFERSON COUNTY (TEX.) MEDICAL SOCIETY: Annual meeting at Beaumont on December 1. Officers elected: *President,* Dr. Louis Goldstein, Beaumont; *Vice-president,* Dr. John H. Haizlip, Nederland; *Secretary-Treasurer,* Dr. Wilbur E. Thomson, Beaumont; *Censor,* Dr. James M. Gober, Beaumont.

MCLENNAN COUNTY (TEX.) MEDICAL SOCIETY: Annual meeting at Waco on December 2. Officers elected: *President,* Dr. J. M. Witt, Waco; *Vice-president,* Dr. C. C. Collum, Mart; *Secretary-Treasurer,* Dr. E. L. Eastland, Waco.

AMERICAN SOCIETY FOR THE STUDY OF ALCOHOL AND OTHER NARCOTICS: The forty-third annual meeting was held at Philadelphia on December 3 and 4, the following officers being elected for the ensuing year: *President,* Dr. John D. Kindred, New York; *Vice-presidents,* Dr. H. G. Kress, Chicago; Dr. T. A. MacNicholl, New York; Dr. Thomas A. Williams, Washington, and Dr. K. R. M. Maus, U. S. A., Governor's Island; *Secretary,* Dr. C. H. Denton, Miami, Fla.; *Assistant Secretary,* Dr. De L. Carter, New York; *Corresponding Secretary,* Dr. Thomas D. Crothers, Hartford, Conn.; *Treasurer,* Dr. Pitts E. Howes, Boston.

MACON COUNTY (GA.) MEDICAL SOCIETY: Annual meeting at Macon on December 3. Officers elected: *President,* Dr. Thomas H. Hall; *Vice-President,* Dr. Charles M. Richardson; *Secretary-Treasurer,* Dr. R. H. Stovall.

OLDHAM COUNTY (KY.) MEDICAL ASSOCIATION: Annual meeting at Lagrange on December 4. Officers elected: *President,* Dr. J. E. L. Harbold; *Vice-President,* Dr. R. B. Cassidy; *Secretary-Treasurer,* Dr. E. D. Burnett.

SANTA CRUZ COUNTY (CAL.) MEDICAL SOCIETY: Annual meeting at San José. Officers elected: *President,* Dr. F. H. Koepke, Watsonville; *Vice-Presidents,* Dr. W. H. Keck, Santa Cruz, and Dr. A. N. Nettler, Davenport; *Secretary-Treasurer,* Dr. G. P. Tohman, Watsonville.

LOS ANGELES COUNTY (CAL.) MEDICAL ASSOCIATION: Annual meeting at Los Angeles on December 18. Officers elected: *President,* Dr. Luther M. Powers; *Vice-President,* Dr. Charles Whitman; *Secretary-Treasurer,* Dr. George H. Kress.

COWLEY COUNTY (KAN.) MEDICAL SOCIETY: Annual meeting at Arkansas City on December 11. Officers elected: *President,* Dr. W. P. Guy, Winfield; *Secretary,* Dr. B. C. Geslin, Arkansas City; *Treasurer,* Dr. W. T. McKay, Arkansas City.

DAVIESS COUNTY (KY.) MEDICAL SOCIETY: Annual meeting at Owensboro on December 20. Officers elected: *President,* Dr. J. M. Stuart, Owensboro; *Vice-President,* Dr. Z. H. Shultz, Pleasant Ridge; *Secretary-Treasurer,* Dr. J. J. Rodman.

AMERICAN PHYSIOLOGICAL SOCIETY: At the annual meeting held at Philadelphia December 29 and 30 officers were elected for the ensuing year as follows: *President,* Dr. W. B. Cannon, Harvard; *Secretary,* Dr. A. J. Carlson, University of Chicago; *Treasurer,* Dr. J. Erlanger, Washington University, St. Louis. The next meeting is to be held at St. Louis.

AMERICAN SOCIETY FOR EXPERIMENTAL PATHOLOGY: At the annual meeting held at Philadelphia December 29 and 30 the following officers were elected for the ensuing year: *President,* Dr. R. M. Pearce, University of Pennsylvania, (re-election); *Vice-President,* Dr. John F. Anderson, Director of the U. S. Public Health Service, Washington; *Secretary-Treasurer,* Dr. George H. Whipple, Johns Hopkins; *Councilors,* Dr. Harvey Cushing of Harvard, and Dr. David Marine of Cleveland.

AMERICAN SOCIETY OF PHARMACOLOGY AND EXPERIMENTAL THERAPEUTICS: At the annual meeting held at Philadelphia on December 29-30 officers for the ensuing year were elected as follows: *President,* Dr. Torald Sollmann, of Western Reserve University; *Secretary,* Dr. J. Auer, of the Rockefeller Institute; *Treasurer,* Dr. W. deB. MacNimer of New York; *Membership Committee,* Dr. Reid Hunt of New York.

TIPTON COUNTY (TENN.) MEDICAL SOCIETY: Annual meeting at Covington on December 10. Officers elected: *President,* Dr. T. B. Gassaway, Tabernacle; *Vice-Presidents,* Dr. A. S. Witherington, Munford, and Dr. G. W. Crice, Covington; *Secretary-Treasurer,* Dr. L. J. Lindsey.

SALT LAKE COUNTY (UTAH) MEDICAL SOCIETY: Annual meeting at Salt Lake City on December 8. Officers elected: *President,* Dr. E. D. Hammond; *Vice-President,* Dr. Ernest Van Cott; *Secretary,* Dr. R. W. Ashley; *Treasurer,* Dr. E. F. Chamberlain.

TRI-STATE (ARKANSAS, LOUISIANA, AND TEXAS) MEDICAL SOCIETY: Annual meeting at Texarkana on December 9 and 10. Officers elected: *President,* Dr. Preston Hunt, Texarkana; *Vice-Presidents,* Dr. J. B. Runyan of Little Rock, Ark., Dr. J. E. Kingston of Shreveport, La., and Dr. T. J. Allison of Redwater, Tex.; *Secretary,* Dr. J. M. Bodenheimer of Shreveport, La.

**Chiropractors Refused Charter.**—Justice Potter of the Supreme Court of Pennsylvania recently handed down a decision affirming an order of the Common Pleas Court of Pittsburgh denying a charter to an organization known as the Chiropractors' Association of Pennsylvania. The refusal of the charter was based on the ground that the applicant had no legal status under the medical practice act.

**The Late Dr. S. Weir Mitchell.**—At a special meeting of the managers of the Philadelphia Orthopedic Hospital and Infirmary for Nervous Diseases, held on January 5, a special committee was appointed to draft resolutions appropriate to the death of Dr. Mitchell, and to present them at a meeting of the Contributors of the Hospital, shortly to be held. The Orthopedic Hospital was founded in 1869 and the Infirmary for Nervous Diseases in 1875 by Dr. Mitchell. Subsequently the two institutions were merged and Dr. Mitchell was for many years an active member of the staff of the consolidated hospital and later a member of the Board of Managers.

At a special meeting of the Philadelphia Neurological Society, held on January 5, remarks on the death of Dr. Mitchell were made by the president, Dr. George E. Price, and by Dr. Charles K. Mills, Dr. Francis X. Dercum, and Dr. James Hendrie Lloyd, the only remaining original members. Dr. Mitchell was the first president of the society. A resolution of sorrow was adopted.

At a special meeting of the College of Physicians

of Philadelphia, held on January 6, appreciative remarks were made by the president, Dr. James C. Wilson, and by Dr. W. W. Keen, Dr. James Tyson, Dr. Frederick P. Henry, and Dr. George de Schweinitz. Dr. Mitchell was president of the college on two separate occasions and was one of its most eminent benefactors in gifts of time, energy, enthusaism, rare books, and money.

The annual dinner of the Franklin Inn Club, of which Dr. Mitchell was the first and only president, was to have been held on Franklin's birthday, the day of Dr. Mitchell's funeral, but was postponed indefinitely.

At a meeting held January 8 the Library Company of Philadelphia, founded by Benjamin Franklin in 1731, adopted sympathetic resolutions on the death of Dr. Mitchell, who for many years was presiding director of the library.

At a meeting held January 9 the executive committee of the Committee of One Hundred of Philadelphia adopted a minute of regret on the death of Dr. Mitchell. In a sealed communication opened after his death, Dr. Mitchell, the first custodian, in accordance with the conditions imposed by the donor, Dr. Robert Abbe of New York, designated Dr. Simon Flexner of New York, to succeed him as custodian of the watch formerly belonging to Dr. Benjamin Rush and now deposited with the College of Physicians of Philadelphia.

It is reported that just before his death Dr. Mitchell finished an epic poem of five thousand lines, entitled "Barabas," which is believed to be one of the most remarkable of his literary productions.

**Obituary Notes.**—Dr. ANDREW FLINT SHELDON of Lyons, N. Y., a graduate of the New York University Medical College in 1852, a surgeon in the United States Army during the Civil War and inventor of a field hospital tent which is adopted throughout the service, and a former member of the New York State and Wayne County Medical Societies, died at his home on January 4, aged 83 years.

Dr. ARTHUR BERNARD BROWN of New Orleans, La., president of the National Federation of State Medical Associations, a graduate of the Medical Department of the Tulane University of Louisiana in 1901, secretary of the Louisiana State Medical Board, and a member of the American Medical Association and the Louisiana State and Orleans County Medical Societies, died at his home, after a long illness, on December 19, aged 34 years.

Dr. HENRY STIER POLE of Hot Springs, Va., a graduate of the College of Physicians and Surgeons, Baltimore, in 1880, a member of the American Medical Association and the Medical Society of Virginia, and for over forty years a resident and leading physician of Hot Springs, died at the home of his daughter in Lewisburg, W. Va., after a short illness, on December 28, aged 66 years.

Dr. JAMES H. CURTS of Paterson, N. J., a graduate of Trinity Medical College, Toronto, Canada, in 1899, a member of the Medical Society of New Jersey and the Passaic County Medical Society, and of the staff of the Paterson General Hospital, died at his home after a long illness, on December 30, aged 36 years.

Dr. JAMES PARKER STEDMAN of Brockton, Mass., a graduate of the Boston University School of Medicine, Boston, in 1882, one of the organizers of the Brockton Hospital, and at the time of his death a member of the consulting staff, died at his home, after a long illness, on December 24, aged 56 years.

Dr. HENRY T. DUFFIELD of Pittsfield, Ill., a graduate of Washington University, Medical Department, St. Louis, in 1882, and a member of the American Medical Association and the Illinois State and Pike County Medical Societies, having served as secretary, treasurer, and president of the last, died in a hospital in St. Louis, on December 14, aged 60 years.

Dr. FRANZ REDER of New Athens, Ill., a graduate of the University of Munich, Germany, in 1852, a resident of the United States for fifty-three years, and for most of that time a practicing physician of St. Louis, Mo., died in the Deaconess Hospital, St. Louis, from chronic interstitial nephritis, on December 28, aged 84 years.

Dr. JOHN T. KELLEY of Bridgewater, Mass., a graduate of the College of Physicians and Surgeons, Boston, in 1900, died at his home, after a few days' illness, on December 29, aged 35 years.

Dr. DANIEL P. DEMING of Cass City, Mich., a graduate of the Long Island College Hospital, Brooklyn, N. Y., in 1883, and a member of the Michigan State and Tuscola County Medical Societies, died at his home, from blood poisoning following a slight injury to his hand during an operation, on December 26, aged 70 years.

Dr. JOSEPH FRANCIS DESILVER of Atlantic City, N. J., a graduate of the University of Pennsylvania, Medical Department, Philadelphia, in 1900, and a member of the American Urological Association, died at his home on January 1, aged 38 years.

## Obituary.

### EDWARD CHARLES SPITZKA, M.D.

NEW YORK.

Dr. E. C. Spitzka died at his home in this city on Tuesday of this week, at the age of 61 years. The immediate cause of death was apoplexy, though he had been in ill health for some time. He was born in New York, November 10, 1852, and was graduated from the University Medical College in 1873. After a period of study in Vienna and other European clinics he began practice in this city, paying special attention to diseases of the mind and nervous system. From 1881-1884 he was editor of the *American Journal of Neurology*, and from 1885-1887 professor of neurology and medical jurisprudence at the Post-Graduate Medical School. He was a member of the American Neurological Association, of which he was president in 1890, of the New York Neurological Society, and of the Association of American Anatomists. He was the author of a "Treatise on Insanity," published in 1883.

Dr. Spitzka was especially interested in the anatomy of the central nervous system and made many important discoveries in this field; he was one of the founders in 1891 of the American Anthropometric Society, the members of which pledge themselves to bequeath their brains to the society for measurement and examination. He was also a worker in criminal psychology, and his opinion was often sought in medicolegal cases. At the trial of Guiteau for the assassination of President Garfield he insisted that the man was insane and adhered to this opinion although the weight of medical testimony was on the other side. He also made the autopsy on Czolgosz the murderer of President McKinley. He was a man of decided opinions on sociological subjects and had the courage of his convictions, never hesitating to express his views and maintain them, if necessary, in the face of popular and professional opposition.

## OUR LONDON LETTER.

(From our Regular Correspondent.)

ENUMERATIVE METHODS OF STUDYING INFECTIONS—R. S. M. AND ITS SECTIONS—PROCEEDINGS IN SURGICAL, ORTHOPEDIC, ANESTHETIC, OBSTETRICAL, LARYNGOLOGICAL, OPHTHALMOLOGICAL SECTIONS—ANNUAL MEETING OF HOSPITAL SUNDAY FUND—MEDICAL GUILD—MEDICAL MISSIONS—OBITUARY.

LONDON, December 27, 1913.

Sir Ronald Ross, F.R.S., K.C.B., read a communication at the Harveian Society on the "Study of Infections by Enumerative Methods." He dwelt on the advantages of investigators working together in groups or teams, and went so far as to hint that the time has now arrived when advances in tropical medicine can only be made by the organized efforts of such groups. He illustrated his view by describing the investigations carried out by a small team under his own direction in Liverpool. They had worked steadily together for two years on a sum of £900 granted to him by the government. There was an enormous amount of work could be done in this way, but before it could be done further funds were needed. His own team scattered when the money came to an end. Their observations dealt chiefly with the intimate characters and phases of sleeping sickness, of which they had actually discovered a new variety. They also dealt with the effects of drugs in this disease, both in men and animals. Further, some observations were made on blackwater fever, its real nature, and its experimental production in animals. The paper was illustrated by lantern slides and microphotos, many being produced in natural colors. Sir Ronald was cordially thanked for his interesting communication.

The Royal Society of Medicine, since absorbing several other societies, and dividing into so many sections, seems always to be demanding attention. There is perhaps much to be said in favor of this division on the part of specialists who care only to consult with one another, but many fellows desire to take wider views, and for them the journeys to and fro are necessarily increased. I know one gentleman who no longer goes to any meetings, and says the only way to keep an eye on all that is passing is to look through all the journals, for not one of them reports all the meetings, so he spends his spare time in examining one after another such reports as appear. He admits that he thus gives up much of the interest of hearing the discussions, but he gains in physical repose, and obtains a condensed sketch of the proceedings which most interest him, and which he can fill out from former experiences. But to some of the sectional doings during the last two or three weeks: In the surgical Mr. Kempe related a case of brachial arteriovenous aneurism in a man of fifty-six who came for an injured wrist. On applying *x*-rays six shots were seen in the hand, and when told this he said he had been shot twenty-five years previously, and his wife added that in his other arm "they rattle about like a bird singing." A large pulsating swelling was situated below the anterior axillary fold of the brachial. It was traceable into the axilla, and another pulsating swelling was found under the clavicle. No sign of intrathoracic aneurism. It was decided to sever the communication and restore the ordinary circulation. Dissection showed indirect communication through a small but distinct bulb. Mr. Kempe detailed the operation by which he accomplished his aim, and although signs of cardiac dilation were observed, the man considered himself well a fortnight later and reported himself again after another fortnight.

Mr. V. Z. Cope read a paper on the "Early Diagnosis of Ruptured Intestine," and Mr. Raymond Johnson recounted statistics as to forty-four cases he had collected from the records of twelve London hospitals.

Mr. Betham Robinson related a case of endothelioma in the right breast of a single woman of twenty-seven. It was freely removed and the axilla cleared. Five years had passed without recurrence.

In the Gynecological Section an exhibition of specimens has been shown, among them carcinoma of Bertholin's gland, occluded vagina after total hysterectomy, sloughing fibroid and inversion of the uterus, epidiascopic demonstration of Altman's granules in tissues at point of invasion by carcinoma, *fetus amorphus acardiacus*.

Cases and exhibitions have also largely occupied the sections of pediatrics, psychiatry, laryngology, and orthopedics. The last, by the bye, is called a "subsection of surgery," though it is difficult to say why, for it cannot be said to be of less importance than several of the full sections. However, it has been so officially denominated, and the president is Mr. Muirhead Little, senior surgeon to the Orthopedic Hospital. At the meeting on the 11th there were interesting exhibits of apparatus and reports of cases.

In the section on anesthetics Mr. Flemming read an account of the fatalities reported in the newspapers from 1910 to 1912, many of which were meager and of practically no use for the purpose of the section. Sir F. Hewitt took occasion to enforce his views as to the need of reforms in administration and of inquests, and thought the section might follow the example of the General Medical Council and the Association for the Advancement of Science in appointing a committee on that subject.

In the section of ophthalmology experimental glasses, prepared synthetically by Sir William Crookes, P.M.S., were shown. He had made a glass which would intercept about 96 per cent. of the thermic rays—of great importance in reference to glass workers' cataract. Dr. Legge of the Home Office was present and contributed some valuable remarks as to the result of his study of this subject in factories, which showed the disease to be much more frequent among glass workers than had been supposed by the late Mr. S. Snell.

Mr. Bishop Harman then showed photos of an operation he had done to improve the effect of an artificial eye. By narrowing the fissure of the lids it took away the fixed stare which attracts the look of the beholder, who thus will concentrate his look on the natural eye.

At the forty-first annual meeting of the Hospital Sunday Fund, held last week, the council had to present a rather unsatisfactory report. The total sum collected was nearly £3,000 less than in the previous year, and this chiefly relates to collections in places of worship. Legacies and donations are not affected to the same extent, and the council expresses a fear that the falling off may be due to a diminution of people attending church. Sir Savile Crossley stated that notwithstanding the

decrease in the finances, more money had been distributed than in previous years. It was reported that more grants for surgical appliances and convalescent homes had also been made. One reverend gentleman urged his brethren not to accept the situation quietly, but to speak faithfully on the habit of neglecting church—often for motor excursions—and thus neglecting the hospitals through absence at collections. A proposal to make no grant to any hospital permitting vivisection in the laboratory of its medical school was rejected by a large majority.

The National Medical Guild met on Friday to talk about trade unionism for the profession. Dr. Ch. Button presided. About seventy persons were present and a resolution to support the guild was passed by a considerable majority, and the intention was expressed of asking the British Medical Association to recognize the guild as an auxiliary body. One speaker said the British Medical Association should be a purely academic body, and the guild look after material matters. The guild was registered as a trade union, and it was urged that this was the only way in which a fighting fund could be safely maintained for the defence fund of the British Medical Association had practically collapsed. It was remarked that only two institutions were above the law of this country, viz., the king and a trade union. For proof the audience was reminded that recently the law had been strained to help trade unions.

A medical missionary is sometimes welcomed by tribes which jealously exclude everyone else. The Rev. C. Len Wilson, who penetrated the hinterland of the Soudan, west of the White Nile, and into Bahr-el-Ghazal, says it was mainly through the work of the medical members and the mission that the confidence of the curious people of those regions was secured. He regards a mission that goes out without doctor and nurses as only half equipped. A teacher who cannot help the native in the time of illness will be of little use.

Sir J. J. Trevor Lawrence, Bart., died on the 23d inst., within a week of completing his eighty-second year, for he was born on December 30, 1831. He was the second baronet, having succeeded his father, Sir William Lawrence, president of the Royal College of Surgeons, surgeon extraordinary to Queen Victoria, and many years a leader in the profession. Sir Trevor qualified in 1853, and entered the E. T. Company's medical service and served in London for some ten years, including the mutiny period. In 1867 his father died. Some years later he was elected to the House of Commons, and continued a member until 1892, when he retired. He was a devoted member of the Royal Horticultural Society, elected its president in 1885, and continued to serve it in that position until the present year. It was mainly due to his energy and influence that the society's centenary was celebrated by the erection of the present hall. He was specially famed for his knowledge and cultivation of orchids, but was a noted collector of many other rare plants. In 1902 he received the K. C. V. O.

**The Hot Air Douche in the Treatment of Suppurating Wounds.**—M. H. Roziès reports that he has obtained excellent results with this method of treatment in traumatic and operative infected wounds. The hot air is bactericidal and favors cicatrization.—*La Presse Médicale.*

## OUR VIENNA LETTER.

(From Our Regular Correspondent.)

SUGGESTIVE THERAPEUTICS IN PERTUSSIS—HEMATURIA AND RENAL ARTERIOSCLEROSIS—SYPHILIS OF THE PELVIS OF THE KIDNEY—TUBERCULOSIS OF THE STOMACH.

VIENNA, December 15, 1913.

At a meeting of the Vienna Medical Society Hamburger reported a case of whooping cough, which he treated effectively by means of the psychical or suggestive method inaugurated by Czerny of Heidelberg. The case was that of a child three and one-half years old who had suffered for more than five weeks from whooping cough and who was cured with the aid of faradization within two days. Hamburger believes that pertussis, if of more than five weeks' duration, is often but a neurosis and easily influenced by energetic suggestive therapy. For this purpose Hamburger thinks that faradization is very well adapted.

Arteriosclerosis of the kidneys as the cause of hematuria is a very rare occurrence. Broiss reported a severe case of this kind, resisting every therapy, in which nephrectomy revealed a pronounced arteriosclerosis of the kidneys. In another case a cystic kidney was the cause of the hematuria.

Schwarzwaid has observed three cases in which renal arteriosclerosis was the cause of profuse hemorrhages. He calls the hitherto unknown complex of symptoms, consisting of hematuria and intermittent colic, in analogy with other diseases having an arteriosclerotic basis, the so-called "claudication intermittente par oblitération artérielle" (Charcot), "dysprasia renis intermittens angiosclerotica." The indication for operation is an imperative one. The proper surgical procedure is to perform a nephrectomy or, where possible, a conservative operation on the kidneys; decapsulation or nephrotomy, is still better.

Syphilis of the pelvis of kidney as the only manifestation of florid syphilis is a very rare occurrence. Dr. Gottlieb demonstrated a case of this condition in which there existed a mere catarrh of the bladder and a pyelitis ascertained through catheterization of the ureters, but there was otherwise nothing to indicate syphilis except a positive Wassermann reaction. The pyelitis and cystitis fully subsided after six injections of salicylate of mercury.

Tuberculosis of the stomach or of the pylorus is a rare condition. Four different forms have been recognized: the ulcerating, the hypertrophic, the inflammatory, and the sclerotic forms, and a variety in which the pylorus is compressed by bunches of tuberculous glands. An example of a fifth variety was demonstrated by Schlesinger at the last meeting of the Vienna Medical Society. At autopsy there was discovered a submucous abscess surrounding the pylorus. This abscess communicated with the stomach through small openings. In the neighborhood of the pylorus there were small tubercles in the serosa. During life there had existed signs of stenosis. The sudden appearance of these symptoms gave rise to the suspicion that a most unusual condition was present; coexistence of pulmonary phthisis indicated the probable tuberculous character of the disease. Death occurred early. Schlesinger says that the diagnosis in these cases unfortunately can very seldom be made during the life of the patient.

5. The Passing of Paranoia. J. B. MacDonald.
6. Report of a Case of Brachial Neuritis Due to Periostitis of Rib. R. W. French.

**1. Carbon Monoxide Poisoning.**—W. H. Robey states that Edsall has pointed out that carbon monoxide poisoning in addition to the acute illness and possible fatality which it may cause is also responsible for the production of certain subacute and chronic disorders. Sedgwick regards the chronic effects as more important than the acute ones. The intoxication from illuminating gas is usually more severe than that from simple carbon monoxide, but the latter is the chief agent in illuminating gas poisoning. In comparing the relative toxicity of coal gas and water gas, the author states that the increased amount of carbon monoxide in water gas makes a small volume of gas fatal in a much shorter time. Coal gas by its very strong odor made its presence known sooner to other inmates of the house, and while the victim might be unconscious when found, he had not as a rule inhaled sufficient carbon monoxide to make treatment useless.

**2. Flatfoot.**—H. W. Marshall points out that normal conditions in feet depend always upon a combination of elements, and never upon any one of them independently. These underlying factors are grouped into three divisions: first, the amount of weight borne and the lengths of times it is endured; secondly, the degree of healthy vitality existing at the particular time in ligaments and muscles supporting the arches that is represented by their strength; and thirdly, favorable and unfavorable qualities of blood circulating through the feet at the given time. This is the only working formula that is applicable universally to all cases, and it should come to mind as the most practical way of viewing each patient, instead of by special features alone in each one, such as shapes of feet, height of arches, occupations, body weights, physical conditions, etc.

**3. Hair Cast of the Stomach.**—G. A. Moore presents a review of fifty-four cases of this condition, fifty-three of which have been reported in the literature. The condition is rarely found in men. Forty-eight or over 89 per cent. of the cases were girls or young women, the average age of whom was nineteen and one-half years. Confession of the habit before or after operation was obtained in less than half of the cases. Therefore, a denial of having eaten hair as in my case is of very little importance. The prevalent idea that foreign bodies in the gastrointestinal canal are found only in the insane is erroneous. But 6 or 11 per cent. of the entire number were mentally deficient or insane. Nausea or vomiting, though mentioned in but twenty-eight of the cases, probably occurs more frequently, as gastric symptoms are less pronounced when the patients are kept at rest. Hematemesis, which is considered an important symptom by English writers, is of rare occurrence. In thirty-nine of the cases a tumor was reported to have been found which was situated in the epigastrium in eighteen patients, in other regions of the abdomen in eleven cases, and the location is not mentioned in ten. These masses are sausage-shaped, very firm, smooth and freely movable. Of the diagnoses suggested, the spleen seems to be the most frequent offender, being reported in eight cases, malignant tumor in five cases, floating kidney in four cases. Omental tumor, tuberculous infiltration, twin pregnancy, hydatid, gumma and cyst of the pancreas are the rarer diagnoses. Statistics, especially of the earlier cases, prove conclusively the futility of expectant methods. Of the twenty-two cases treated without operation, nineteen died, a mortality of 86 per cent. Three vomited masses of hair or passed hair in the stools and recovered.

8. Prevention of Insanity. R. A. Goodner.
9. Mixed Chancre. S. Steiner.
10. Röntgen Rays in Eczema of the Hands. F. Wise.

**1. Prevalence of Nasal Catarrh.**—W. Freudenthal states that in order to lessen the great prevalence of catarrh prevailing systems of heating should be changed so as to allow much more moisture to evaporate in each living room. This is especially important in schools or meeting halls of every kind. A pail of water in front of the heater is ineffective. One should employ other means in order to overcome the deficient humidity indoors. In order to prevent colds excessive clothing should not be worn. Young people should be hardened to exposure to draughts, rain, snow, and other inclemencies of the weather.

**3. The Sella Turcica in Some Epileptics.**—L. Pierce Clark and E. W. Caldwell note that pronounced variations of the bony formation of the sella turcica in epileptics were first pointed out by Johnston of Pittsburgh, who has not yet published his full study of the subject. Three types of the pathologically deformed and enlarged sella have been distinguished and classified by Cushing. The one which is frequently found in epileptics is associated with a thickening of the clinoid processes and dorsum sellæ. Here the enlargement is accompanied by thickening of the walls, but, inasmuch as Cushing states that this type is confined to the acromegalics and gigantics, he believes the bony thickenings are merely a feature of the osseous tendency to overgrowth which, obviously, throws no light on the condition which is present in some epileptics.

**5. Traumatic Rupture of Urethra.**—C. G. Cumston concludes that in all cases of traumatic urethral rupture perineal incision should at once be resorted to without any attempt at urethral catheterism. External urethrotomy with the introduction of the temporary catheter is the only rational treatment in complete rupture with infection and contusion of the soft parts. In incomplete rupture, when there is not much contusion of the tissues, and infection is absent, immediate suture of the urethra and soft parts of the perineum is to be attempted, with the formation of an outlet for the urine by suprapubic cystostomy or urethrostomy in the membranous urethra.

**4. Pellagra.**—J. F. Siler, P. E. Garrison, and W. J. MacNeal conclude from their investigations that the supposition that the ingestion of good or spoiled maize is the essential cause of pellagra is not supported. Pellagra is in all probability a specific infectious disease communicable from person to person by means at present unknown. The authors have discovered no evidence incriminating flies of the genus *Simulium* in the causation of pellagra, except that these flies are universally distributed throughout the area studied. If pellagra is distributed by a blood-sucking insect, *Stomoxys calcitrans* would appear to be the most probable carrier. The authors are inclined to regard intimate association in the household and the contamination of food with the excretions of pellagrins as possible modes of distribution of the disease. No specific cause of pellagra has been recognized.

**10. The Diet in Gastric Ulcer and Hyperchlorhydria.**—J. B. Nichols is of the opinion that much of the current dietetic practice in gastric ulcer is based on erroneous grounds. There is one peculiar factor of this condition that he holds is of the utmost importance, namely, the corrosive action of the gastric juice. Wherever the other determining conditions may be, this is a potent factor in producing or maintaining peptic ulcers, and a fundamental and peculiar object in the treatment is the reduction to a minimum of this factor. Pawlow has shown that the flow of gastric juice takes place in two stages and under two influences when food is ingested. First, there is an immediate flow under psychic influence, and again, fifteen to forty-five minutes later, a chemical stimulation by certain of the foodstuffs. Theoretically, it would be of use to prevent the first factor by using unappetizing foods. The substances active in stimulating the secondary flow have been found to be water, impure peptones, meat extractives, and caffeine. Some ingredients of the diet, such as carbohydrates, have no special chemical action on the gastric juices, and organic acids (acetic, citric, lactic, butyric) are also included by Foster and Lambert under this head. Among substances that inhibit gastric secretion the author mentions sodium bicarbonate and fats, and the fatty diet for gastric ulcer is based on these facts. While it has not been extensively used, the author claims that its efficiency has been demonstrated and that it is capable of giving satisfactory results in many cases. Vegetable oils and milk-fat have been mostly used. The high caloric value of cream makes it of special value in gastric ulcer. One quart a day yields sufficient calories for a small person leading a quiet life and the additional calories required in others can be furnished by eggs, bread, etc., in moderate quantities.

**14. Cough Dilatation Time as a Measure of Heart Function.**—J. B. Guthrie calls attention to a symptom which he considers of importance in determining the condition of the heart muscle. He has found by the use of the light percussion method for outlining the heart borders that the act of coughing dilates the heart, as shown by the Roentgen ray and by percussion. At first he thought this only occurred in cases of extreme cardiac weakness, but with later experience he no longer holds this opinion. The healthy heart dilates on coughing to a degree perceptible by roentgenoscopy, but not by percussion. The graver the condition the longer the dilatation lasts. The test consists in measuring the horizontal distance between the resting position and the heart borders after coughing or after forcing the breath, as in horn blowing, together with the time necessary for the heart to return to resting position after cough dilatation—that is, reaction time. It is not possible to obtain correct heart outlines, except through the use of the lightest percussion blow with the minimal force necessary to produce sound waves over resonant structures. One who uses heavy percussion must fall back on the orthodiagraph or fluoroscope in studying the cough dilatation. The author has not seen any bad effects from the use of the test; the three coughs given at the word of command hardly call for more effort than the patient often makes voluntarily. From a surgical point of view it would seem from our present knowledge that it would be hazardous to operate under anesthesia on a patient who has a cough dilatation time of over five minutes. The danger line will probably be shown to be considerably below this. The use of this test in preoperative examination should reduce the number of dangerous "unknown" cardiac conditions. From a therapeutic point of view the work shows wherein lies one of the graver dangers to cardiac patients. Cough is a strain that they cannot always avoid and that calls for treatment in weak patients.

## The Lancet.

*December* 27, 1913.

1. Some Points in the Diagnosis and Treatment of Granular Kidney. Samuel West.
2. Concussion Cataract: Its Medicolegal Aspect; with Notes of an Unusual Case. P. Dunn.
3. The Relation of the Thyroid to Antitoxin. R. Farrant.

**1. The Diagnosis and Treatment of Granular Kidney.**—Samuel West states that granular kidney is a form of chronic interstitial nephritis, yet all forms of chronic interstitial nephritis, even if bilateral, are not granular kidney. For instance, the gouty kidney, so-called, is a mixture of interstitial fibrosis with cell degeneration, yet gout has nothing essentially to do with granular kidney, for even in long-standing gout the kidneys need not be granular, nor is gout more than an accidental—*i.e.* not a necessary—accompaniment of granular kidney. Both gout and lead are frequently given as causes of granular kidney. They are not infrequently associated with it, yet the true relation is probably the contrary to that suggested, the patients being especially liable to these affections, because their kidneys are granular and elimination defective, so that

they are not causes of granular kidney, but its consequences. The characteristic symptoms of granular kidney are: (1) the arterial thickening; (2) the increased arterial tension; (3) the character of the urine; (4) the hypertrophy of the heart, and (5) the retinal changes. The arterial thickening in the early stage of granular kidney is largely muscular, as can be shown by the effect of nitrite of amyl which relaxes the muscular tissue, but has no action on fibrous tissue. The arterial tension in granular kidney varies. It ought to be above normal. With a low tension the patient is not so well. The amount of albumin in the urine is small, sometimes merely a trace. The most important fact about it is that it may be absent at some time of the day or even be absent altogether for days or weeks. As a rule, however, it is persistent, and does not vary much in amount from day to day or at different times of the day. As long as albuminuria occurs as the only symptom in the young it is probably of no significance, but if it be associated with other signs, and especially with arterial thickening, even in slight degree, more caution must be taken in pronouncing it to be of no gravity. For it may be the early state of granular kidney, for this is a disease which commences in early life and is not really rare in the quite young. Even when albuminuria is the single sign, its gravity increases with every year of age after 25, because of the increasing probability of its being due to granular kidney. In the treatment of granular kidney in its early stages there are two things to be avoided: first, a drastic dietetic treatment which will injure the general health, and second, the risk of converting the patient into a renal hypochondriac. When symptoms arise they must be treated on general principles. For sleeplessness and nervous restlessness at night no sedative is better than cannabis indica. If uremia is imminent it may be staved off by free purgation, active diaphoresis, and oxygen inhalation. Pilocarpine is a great standby in granular kidney. On the basis of an experience extended over a number of years the author advocates the use of renal extract, freshly prepared from the kidney of the pig. This substance must be patiently and continuously administered for a long time in order that favorable results may be obtained.

3. **The Relation of the Thyroid to Diphtheria Antitoxin.**—R. Farrant points out that certain diseases, and especially certain toxemias, cause hyperplasia of the thyroid gland in man and animals. Among these diphtheria toxin, particularly, has been examined, and it is found that a small dose is sufficient to elicit hyperplasia in a susceptible animal, but that as immunity is acquired the thyroid no longer undergoes hyperplasia under the toxin. The hyperplasia thus decreases as the antitoxic value of the serum increases. The thyroid gland, in other words, is protected from the action of the toxin by the presence of antitoxin in the serum. There is no reason to suppose that any special relation exists between antitoxin formation and the thyroid gland—for example, the latter is not antitoxic itself. In some cases commercial antidiphtheritic serum fed to rabbits caused death with the same symptoms as thyroid feeding; this may be due to the serum of partially immunized horses containing an unusual amount of thyroid secretion from the hyperplasia. But this could not be controlled, as the amount of iodine in pure serum was too small for accurate estimation. The pure antitoxic serum does not appear to contain any estimable increase of iodine.

1. **The Nature of Old Age and of Cancer.**—By Hastings Gilford. (See page 115.)

2. **Intratracheal Insufflation of Ether.**—F. E. Shipway points out the following advantages of this method of anesthesia: A free airway is obtained. There is an even and constant administration of a weak warm vapor. The anesthetist is out of the way of the surgeon. The recurrent air stream prevents the aspiration of blood, mucus, etc. Operations on the abdomen are facilitated by the slight character of the respiratory movements. Operations which may involve the accidental opening of the pleura can be done without risk or anxiety. Shock is diminished. The objections to this method are three in number: (1) The apparatus is costly. (2) The apparatus is somewhat cumbersome and the outfit elaborate. (3) The introduction of the catheter is the stumbling-block which at present stands most in the way. There has been such a considerable amount of evidence collected, the method has been so thoroughly tested, and the comments by onlookers on the type of anesthesia, its advantages, and the freedom from postoperative distress have been so uniformly favorable that intratracheal insufflation may be said completely to have made good its claims and definitely to have established its value.

## Berliner klinische Wochenschrift.

*December* 22, 1913.

**Physical Therapy of Surgical Tuberculosis.**—Wachsner, reviewing the various methods, old and new, in their application to surgical tuberculosis, states that we have now resumed an active therapy, after a period of passive treatment as characterized by plaster-of-paris and let alone. At present we are depending on sunlight, artificial light, chemical rays, electricity, hot air, *x*-rays, etc. Dressings, instead of being fixed, are removable. Recumbent periods may alternate with efforts at functional betterment. Modern physical therapy provides for cosmetic effects and attempts to make of the patient a social unit. It is hardly possible to carry out all these measures in an ordinary orthopedic clinic.

**Operative Cure of Multiple Metastatic Liver Abscesses.**—Heinemann gives the statistics of this sequence. In 155 cases thus treated there were two operative recoveries, and a single case without operation. This leaves the mortality about 98 per cent. The author reports an operative cure of his own and has looked over the very recent literature with negative results. The author's patient, a young man, had had an osteomyelitis of the right tibia for five years which had been operated on several times. There had been no evidence of fistula formation or sequestration —nothing beyond periosteal abscesses. At a certain date and without manifest connection with the bone, an obscure type of fever set in and in time assumed the clinical picture of typhoid. Incidentally the liver was found much enlarged and the diagnosis of typhoid seems to have been abandoned, as no blood tests seem to have been made. The contour of the liver suggested an abscess and a puncture brought away much pus, which was then removed through an incision. The fever vanished at once, but there soon became apparent evidences of another abscess. The long needle pierced the liver six times before pus was again struck. The small quantity evacuated suggested that there might be a number of small abscesses. The author was in doubt as to further surgical procedures. In the meantime the needle tract was drained by a specially

devised apparatus and healed well. In the same manner nine other small abscesses were successfully located and treated. These appeared one by one, each heralded by a chill. In four weeks 100 trial punctures had been made and no apparent harm resulted. All the smaller abscesses lay deep in the enlarged right lobe and directly in front of the vertebral column. Recovery was complete, patient having resumed his occupation.

**Simulation of Typhoid Fever by Marked Hodgkin's Disease.**—Rosenthal has discovered a new condition which can closely simulate typhoid, although the case reported is very likely unique. It was one of lymphogranulomatosis of the spleen and retroperitoneal glands of the sort seen in a fully developed Hodgkin's disease. Had the subject survived the lesions might have diffused themselves. Such conditions have been found post mortem, and K. Ziegler named them the typhoid form of Hodgkin's disease. Cases have been seen a few times in which a fully developed Hodgkin's showed a typhoid fever curve. The author's patient, aged 38, robust, was suddenly stricken with fever lasting six weeks, from which he is said to have recovered, but soon after developed a relapse or recurrence when he was seen by the author for the first time. His mind was confused and he had had one epileptic convulsion. The physical symptoms consisted chiefly of an enlarged spleen. No Widal reaction or roseola. Diagnosis continued fever of unknown origin. A recurrent type of fever later replaced the continuous type. Aside from two roseola spots nothing had been seen at any time to suggest typhoid. The hemoglobin had steadily sunk, and a stuporous state attended the latest relapse. Death occurred from severest cachexia, patient having been ill four months. Diagnosis post-partum.

### Deutsche medizinische Wochenschrift.

*December* 11, 1913.

**Tuberculosis.**—The entire number, which is a Koch memorial issue, is devoted with one or two exceptions to articles on tuberculosis by Koch's pupils, and others. The anniversary commended is his birthday. Had he lived he would have been 70 years of age. Loeffler lays great stress on antituberculous dispensaries, an idea of Wilkinson, formerly of Sydney but now of London, which is being carried out in Germany. He regards this as a very great step ahead in the conquest of the disease. As Wilkinson was one of the earliest practitioners to use tuberculin, he thus becomes one of the forces in the warfare against tuberculosis. Ehrlich gives Koch the entire credit for solving the problem of specificity. Through the scope and success of his discoveries he becomes one of the few really great scientists of all time. Kossel states that Koch made scientific sanitation possible, as shown in the intelligent campaigns against cholera, typhoid, etc. In this way the subject of "disease carriers" became known. The soil could also be shown to act as a carrier, while drinking water could be shown to be infected. Under the head of "hosts" as transmitters of possible disease, Koch's work was entirely new. This problem led him to Africa, where he may be said to have laid the foundation of modern tropical medicine. His brilliant results on "sleeping sickness" were rendered abortive by the deferred toxicity of alcohol. Uhlenhuth and Hügel have recently sought to substitute a synthetic containing antimony, having the type corresponding to atoxyl in the treatment of spirochætei and trypanosome diseases. They have studied a number of these combinations. The latter seem to be a step in the right direction. Lockemann, writing on the biology of the tubercle bacilli says that much stress is now laid upon the determination of the weight of the cultures, since this indicates in a measure the rapidity of growth of the culture. In a few weeks the cultures attain a maximum of weight, and then slowly decline, as a result of autolysis. The different composition of culture media has apparently no influence on the growth of the human bacillus. Möllers has studied the fluid portion of cultures with reference to the presence of an antigen, and finds that the maximum antigen content against the bacillus occurs at about six weeks. The actual specific substance is a product of the metabolism of the bacillus. The course of the weight curve of a liquid culture of the latter shows a great similarity to the antigen curve. Stiner and Abelin describe attempts to increase the local resistance against tuberculous infection. Skin was treated (guinea pigs) beforehand with an ointment prepared from Old Tuberculin, but without protective results. Another ointment was made with borini tuberculin, and this appeared to delay infection and limit it to regional lymph nodes. Further study will be necessary in this province. Ruppel treats at great length of tuberculin, of the progress in our knowledge since Koch's death (nearly four years ago), with especial bearing on therapeutic preparation. Koch's ideas seem to hold good against the arguments of others. We know now that the bacillus contains at least three toxins which give to it its specific quality, to wit, a nucleinic acid, a nuclein, and a nucleoalbumin. These substances all disintegrate very easily, and it is very evident that each one contains certain toxic building stones in common, which possess a marked degree of resistance. However, clinically the toxic effect comes from all constituents jointly. More recent writers who have discovered the presence of glycerides in the bacilli attach great biologic importance to them. As a matter of fact the lipoids of the bacilli have always been the great obstacle to manipulation of the latter. A beautiful monument to Koch has recently been erected in Japan in May of this year. The dedication services were of the Shinto rite.

---

**Congenital Insufficiency of Ocular and Facial Movements.**—L. Guthrie reports the case of a boy, aged 4 years, who was born at full time and after an easy labor. Imperfect closure of his eyes was noticed at birth, and his face was devoid of expression. Present condition: Intelligence normal, speech somewhat defective, general nutrition and development fair. The whole of the face is motionless as far as the mouth; the skin of the face is smooth and not tightly stretched. The visage resembles in some respects the "myopathic facies." The eyes cannot be fully closed, the eyeballs are in mid-position, and the only ocular movements which can be performed are elevation and convergence, downward and inward. The pupils are equal, active to light, less so on accommodation. When crying, tears are shed, but no facial contortions are visible; laughter is only represented by guttural grunts. The upper lip projects slightly and is flabby; the lower lip is not everted as in myopathy. The orbicularis oris is not paralyzed, for he can purse his lips and also blow out his cheeks, though feebly. The escape of the orbicularis oris is probably due to association of its action with that of the tongue, the movements of which are normal. Movements of the palate and masticatory muscles are also normal. Electrical reactions cannot be obtained in any of the facial muscles except the orbicularis oris. The condition is regarded as an unusual form of myopathy affecting the muscles supplied by the third and seventh nerves.—*Proceedings of the Royal Society of Medicine.*

# Insurance Medicine.

## SUGGESTIONS TO MEDICAL EXAMINERS.

BY THE INSURANCE EDITOR.

### THE VALUE OF MODERN METHODS FOR THE DETECTION OF SYPHILIS TO LIFE INSURANCE COMPANIES.

THE mortality among insured lives with a history of syphilis is excessive, going over 100 per cent. higher than the normal rate in some classes of cases. The selection was based on the time elapsed from the date of the last treatment and manifestation of the disease and whether or not there were any indications of the previous disorder at the time of the examination. Whenever there was a history of tertiary lesions, the applicants were rejected. This method, though crude, has been the only one available, and it is not difficult to understand how applicants with dormant disease or obscure lesions, impossible to discover in an ordinary examination, passed inspection.

The Wassermann and Noguchi tests have not been required in life insurance examinations until the technique and application of the tests have fairly passed the experimental stage, so that the results would afford a reasonable amount of assurance when carried out by experienced hands. The medical officers of the companies have utilized the tests in isolated cases, but there is a tendency towards a general recognition of these important procedures in routine work. It should not be assumed, however, that an infallible means of diagnosis has been provided in these measures and that there will be no uncertainties in the results. The first burst of enthusiasm has passed and the true value and status of the tests are becoming more evident as experience with them widens. Some confusion is created at the present time by reports that the Wassermann gives a positive reaction more or less frequently in the presence of plasmodia. If these reports prove to be well founded, the test will lose much of its practical value in malarious districts. With our incomplete knowledge of the subject, we are not certain as to the exact circumstances under which a positive test occurs in other conditions than syphilis. It has been explained that it is due to faulty technique or in drawing the line too fine instead of adhering to a certain standard. After all is said, however, the Wassermann and Noguchi tests may be employed with advantage, but only when great care and discrimination are observed.

The mortality rates for which lesions of the nerve centers and of the cardiovascular system are especially responsible are constantly increasing. It has been found through the aid of the Wassermann test that vestiges of old and supposedly cured syphilis are still present in a surprisingly large percentage of these cases. In many of them no history of specific disease was obtainable. It naturally follows that a scientific and more definite diagnosis of syphilis is of considerable value to life insurance companies in the disposal of these risks. Unfortunately, much difficulty will be experienced by the companies in determining whether syphilis of the nerve centers exists on account of the necessity of examining the spinal fluid before a satisfactory diagnosis is possible.

The preferable and most reliable plan for conducting the tests is as follows:

After the cessation of all treatment and symptoms the Wassermann should be applied every three months during the period of a year. A combined Wassermann and Noguchi would be still more valuable, as it is occasionally found by laboratory men that these two tests do not agree with each other, and it must be inferred that syphilis continues to exist if either of them is positive. After a year has elapsed without symptoms or treatment all reactions during the interval having been negative, a provocative injection of salvarsan or neosalvarsan should be administered and followed by a Wassermann or a combined Wassermann and Noguchi in from twenty-four to forty-eight hours after, and again in about ten days. The subject should abstain from alcohol for forty-eight hours previous to each of the final tests.

Some observers believe, however, that even when no tests have been made during the year following the disappearance of all symptoms and the cessation of treatment, a single provocative dose of salvarsan, followed by a negative Wassermann, is sufficient to signify that the syphilis has probably been eradicated. The companies, by force of circumstances, will likely find it expedient to exact the more simple procedure, as it will usually be impossible in practice to have the stringent precautions carried out. They should not be satisfied, however, with less than a Wassermann some time during the year after the cessation of treatment, about four or five months, and a final provocative Wassermann at the end of the year. If more than one year, in fact, if many years have gone by since the cessation of treatment, a provocative injection, followed by a Wassermann, should be required, as syphilis can never be regarded as cured unless there is some evidence.

The tests for syphilis are not complete for insurance purposes unless accompanied by the taking of the blood pressure, as cardiovascular changes may have taken place before the cure of the disease.

If the final tests are satisfactory, the applicant may be considered for an endowment contract or a rated-up policy. Applicants who have had syphilis are not eligible for life insurance on any policy which does not terminate at or about the age of fifty-five.

Owing to the peculiar circumstances under which the business of life insurance must be conducted it is not expedient or good practice to have a physician, as a medical representative of a company, take any part in the carrying out of these tests. The reasons for this objection may be summed up as follows:

First. A company is liable to be plunged into a legal controversy in the event of a real, imaginary, or simulated disturbance which may be attributed to some part of the procedure.

Second. Some applicants who have syphilis, but have considered themselves cured, might claim that the disease had been started up afresh by the provocative treatment, and it would be difficult for the legal representative of a corporation to convince the average jury that the company was blameless in the matter.

The only practicable plan is to have the tests conducted under the supervision of the applicant's attending physician. The specimens obtained by the attending physician should be sent to the laboratory of some analyst who is recognized as unquestionably competent and expert in this line of work. On receipt of a certificate furnished by the applicant on the termination of the tests the company will be in a position to decide on the merits of the case.

# Book Reviews.

KRANKENPFLEGE LEHRBUCH. Herausgegeben von der Medizinalabteilung des Königlich Preussischen Ministeriums des Innern. Dritte neu durchgesehene und ergänzte Auflage. Mit 5 Tafeln und zahlreichen Abbildungen im Text. 361 pages. Price 2.50 marks. Berlin: Verlag von August Hirschwald, 1913.

THE commission that revised this book decided that the original plan of the book, which is an excellent one, remain unchanged, and only the most recent advances in medical science and practice as they affect nursing be added. The book is for the use of male and female nurses who must possess, for its proper appreciation, the minimal education required by nurses registered in the empire. The book contains short concise aphorisms and numerous illustrations. There are 14 main divisions which deal respectively with the structure of the body, diseases and their manifestations, furnishings of the sick room, care and diet, report to the physician, aid during the physician's examination, first aid in various accidents, care of the transported sick, care of the dying, duties of nurses, their deportment toward the sick and toward the family doctor, priests, etc., cardinal principles of the care in the puerperium and of the infant, care of insane, etc. Changes or additions have been made regarding the furnishing of the sick room, the use of disinfectants, artificial respiration, detection of early cancer, etc.

THE PRACTICAL MEDICINE SERIES. Comprising ten volumes on the Year's Progress in Medicine and Surgery. Under the general editorial charge of GUSTAVUS P. HEAD, M.D., Professor of Laryngology and Rhinology, Chicago Post-Graduate Medical School. CHARLES L. MIX, A.M., M.D., Professor of Physical Diagnosis in the Northwestern University Medical School. Volumes I. and VI. GENERAL MEDICINE. Edited by FRANK BILLINGS, M.S., M.D., head of the Medical Department and Dean of the Faculty of Rush Medical College, Chicago, and J. H. SALISBURY, A.M., M.D., Professor of Medicine, Chicago Clinical School. Series 1913. Price $1.50. Chicago: The Year Book Publishers.

IN the Practical Medicine Series the field of general medicine is covered in two volumes, Volume I. and Volume VI. The first of these treats of diseases of the circulatory organs, the blood vessels, the blood, the blood making organs, the ductless glands, the kidneys, and diseases of metabolism and certain infectious diseases. The authors cite many interesting cases and call attention to the newer methods of diagnosis and treatment. The second volume, devoted to general medicine, covers the year's work in diseases of the stomach, intestines, liver, pancreas and spleen, and infectious diseases not included in Volume I. There is a short chapter on dietics. The book is valuable as it affords a rapid yet comprehensive review of the year's progress in the subjects treated.

THE MEDICAL EPITOME SERIES. PATHOLOGY GENERAL AND SPECIAL. A Manual for Students and Practitioners. By JOHN STENHOUSE, M.A., B.Sc. (Edin.), M.B. (Tor.), formerly Demonstrator of Pathology, University of Toronto, Toronto, Canada. Second Edition, Revised and Enlarged, Including a Selected List of State Board Examination Questions. Illustrated with twenty-nine engravings and a colored plate. Price, $1.00. Philadelphia and New York: Lea & Febiger, 1913.

THIS little book is intended to serve as a guide to the medical student at the very beginning of his studies, and to render more intelligible the larger and more important volumes which he is expected to read. The work seems to be well done, and we note that Dr. Stenhouse is now responsible for the whole volume.

DIET IN HEALTH AND DISEASE. By JULIUS FRIEDENWALD, M.D., Professor of Gastroenterology in the College of Physicians and Surgeons of Baltimore, and JOHN RUHRÄH, M.D., Professor of Diseases of Children in the College of Physicians and Surgeons of Baltimore. The Fourth Edition thoroughly Revised and Enlarged. Philadelphia and London: J. B. Saunders & Co., 1913.

THE many changes of opinion held by authorities on diet and the many new facts that have been added to our knowledge of foods and metabolism have led the authors to make rather extensive alterations in this edition. A section on the mechanism of digestion has been added, and the chapters on metabolism and the prescribing of diets have been rewritten. The portion of the work on salt metabolism has been rewritten and tables showing the latest additions to the knowledge of this subject have been added. Diet in its relation to several diseases has been rewritten, and a number of entirely new subjects have been considered, as duodenal alimentation and the use of the soy bean. The chapter on infant feeding has been revised in accordance with the modern trend of thought on this subject.

The object of the authors is to furnish a practical reference book on dietetics for the busy practitioner and they state that they have no dietetic fads which they wish to exploit, but that they have aimed to present the subject of dietetics as they understand it in the light of modern scientific research. While the scientific work which has formed the basis of the diets prescribed is reviewed briefly, the work as a whole is eminently concise and practical. The diet lists for various diseases and for use after surgical operations cannot fail to be both instructive and suggestive to the practitioner. The volume includes lists for army rations, diet lists for prisons and hospitals, and a carefully prepared table of the chemical composition of American foods, all of which will be found valuable to those catering to institutions or large numbers of people.

A TREATISE ON THE DISEASES OF WOMEN. For Students and Practitioners. By PALMER FINDLEY, B.S., M.D., Professor of Gynecology, College of Medicine, State University of Nebraska; Gynecologist to the Clarkson Memorial Hospital and Douglas County Hospital; Fellow of the American Gynecological Society; Fellow of the American Association of Obstetricians and Gynecologists; Fellow of the Chicago Gynecological Society. Illustrated with 632 engravings in the text and 38 plates in colors and monochrome. Price, $6.00. Philadelphia and New York: Lea & Febiger, 1913.

THIS book, being the outgrowth of the author's "Gynecological Diagnosis," naturally contains much that was in that volume, but there has been a slight change in the classification of the subject, and details of etiology and treatment have been added. The author has produced a serviceable volume, and one which, in spite of its size, will compare favorably with the best text books on the subject. Several of the chapters are of more than ordinary interest; such are those on non-operative methods of treatment, hygiene and dress, preparation of patient for operation, post-operative treatment, complications following operations, gonorrhea in women, and tuberculosis of the genital organs. The author is careful to include topics which are on the borderline between gynecology and obstetrics; too frequently these subjects are not discussed by writers on either of these branches of medicine. The classification adopted by the author is open to criticism. Hemorrhages from the genital tract are considered in the same chapter with clinical history and case records. Menstruation is considered with hemorrhages, but the disorders of menstruation are discussed in another chapter, with backache, diastasis recti, and enteroptosis. Tuberculosis of the cervix is discussed in the chapter on inflammation of the uterus and also in the chapter on tuberculosis of the genital organs. Bacteriology of the normal genital tract is considered in Chapter IV. and also in Chapter XVII. The volume is well printed and abundantly illustrated; indeed some of the illustrations might have been omitted with no loss to the reader and with the advantage of reducing the size of the book.

DIE UNTERSUCHUNG DER LUFTWEGE. Ein Vortrag zur Einführung in die Moderne Rhino-Laryngologie fur Aerzte Und Studierende. Von Dr. P. H. GERBER, A.O., Professor und Direktor der Königlichen Universitäts Poliklinik für Hals- und Nasenkranke zu Königsberg. I. Pr., mit 49 Textabbildungen und 12 Abbildungen auf 4 Tafeln. Preis, 2 M. Wurzburg: Curt Kabitzsch, 1913.

THIS is a reprint of Professor Gerber's lecture on modern rhino laryngology, which was delivered on January 13, 1913, at Königsberg, Prussia. All the latest operations are described with ample illustrations in the text and with 12 radiographs as an appendix. Professor Gerber regrets that rhinolaryngology is so frequently combined with other branches at the medical schools.

A Practical Treatise on Medical Diagnosis. For Students and Physicians. By John H. Musser, M.D., LL.D., Late Professor of Clinical Medicine at the University of Pennsylvania, Physician to the Philadelphia and Presbyterian Hospitals, President of the American Medical Association, etc. Sixth Edition. Revised by John H. Musser, Jr., M.S., M.D., Instructor in Medicine in the University of Pennsylvania; Assistant Physician to the Philadelphia Hospital, Assistant Physician and Physician to the Medical Dispensary of the Presbyterian Hospital, Physician to the Medical Dispensary of the Hospital of the University of Pennsylvania. Illustrated with 196 engravings and 27 colored plates. Price $5. Philadelphia and New York: Lea & Febiger, 1913.

This, the sixth edition of this well-known standard work, has been revised and prepared for publication by the son of the original writer of the treatise. Dr. Musser in the preface to the present edition says that he has endeavored to carry out the expressed purpose of his father to make the work an exponent of objective medicine and to point out the way to acquire precision in diagnosis. While carefully keeping this end in view the author, owing to the great advances made in medical science during the past eight years, has been compelled to practically rewrite the treatise in order to keep it abreast of the times. A good deal of new matter has been incorporated in the section on infectious diseases and new sections have been added to that part dealing with the internal secretions, and indeed the book has been efficiently brought up to date. It is an excellent specimen of the printer's and publisher's art and as a reference book to students and practitioners may be highly recommended.

Surgical Experiences in South Africa, 1899-1900. By George Henry Makins, C.B., F.R.C.S., Senior Surgeon to St. Thomas' Hospital, London; Vice-President of the Royal College of Surgeons of England; late Joint Lecturer on Surgery in the Medical School of St. Thomas' Hospital; Member of the Court of Examiners of the Royal College of Surgeons of England, and one of the Consulting Surgeons to the South African Field Force. Second Edition. Price, $3.75. London: Henry Frowde, Hodder & Stoughton; New York: The Oxford Press, 1913.

This is one of the best books on military surgery that we have, in so far as the discussion of the effects of small caliber, high velocity bullets is concerned. The first edition appeared in 1901 and was at once recognized as the most authoritative work extant on that phase of the subject. Since that time it has been widely quoted, both here and abroad, and has readily held the eminent position originally accorded to it. After an introductory chapter, modern military rifles are discussed. Chapter III. deals with the general character of wounds produced by bullets of small caliber. Then follow eight chapters devoted to a consideration of injuries to special structures or regions, namely, injuries to blood vessels, bones of the limbs, the joints, head and neck, vertebral column and spinal cord, peripheral nerves, the chest, and the abdomen. In a short final chapter shells and shell wounds are discussed. As a valuable aid to a thorough understanding of the subject the clinical history of more than 200 cases of all types is given. The book is copiously illustrated, there being 28 full page plates besides 105 illustrations scattered throughout the text. The author has a very easy diction and the book holds the attention even of one not particularly interested in the military side of surgery. This quality, plus its unquestioned value from a technical point of view, has quite naturally rendered a second edition necessary.

Radium as Employed in the Treatment of Cancer, Angiomata, Keloids, Local Tuberculosis, and Other Affections. By Louis Wickham, M.V.O., Médecine de St. Lazare, ex-Chef de Clinique a l'Hôpital St. Louis, and Paul Degrais, ex-Chef de Laboratoire à l'Hôpital St. Louis, Chefs de Service au Laboratoire Biologique du Radium, Laureats de l'Academie de Médecine. Translated by A. and A. G. Bateman, M.B., C.M. With 53 illustrations. Price, $1.25 net. New York: Paul B. Hoeber, 1913.

The widespread interest in the use of radium as a therapeutic agent in the treatment of new growths of various types may be the excuse for the publication of this small pamphlet, though the larger volume published in collaboration by the same authors gives a much more satisfactory review of the subject. However, for those who wish to inform themselves in a somewhat superficial manner of the nature of radium and some of its activities, this translation forms a convenient aid. So much has been claimed for the therapeutic powers of radium without any scientific basis for such claim, that the time has come when the entire subject must be viewed with the utmost scientific scepticism, and only those cases considered, at least in evaluating the treatment of malignant disease, as have had microscopical examinations of the tissues both before and after treatment, and have been followed for a considerable period of years, certainly not less than five. Very few of the writers' cases fall into this class. The most extravagant language is employed throughout the book. It is fortunate, however, that the writers state categorically that, "Operable cancers should be operated upon immediately, without delay; this is an absolutely fixed rule." Such a reminder is much needed as many of those who have been using radium and the *x*-ray have not followed this direction, but have treated operable cases until they have become inoperable. The reviewer has, indeed, in a certain number of tumors seen apparent stimulation of the growth instead of amelioration. The entire question of the permanent therapeutic influence of a truly malignant tumor by radium is, in fact, still open to grave doubt. In many of the reported cures the tumors have never been examined microscopically or the cases have been followed for so short a time that no conclusion is justifiable. While, therefore, it is not impossible that the application of very large amounts of radium (and by large amounts is meant quantities in excess of 300 milligrams of the element, and not the weight of a more or less impure salt) may have some influence upon those forms of epithelioma and carcinoma which run a comparatively benign course, yet practically no evidence exists in print which would warrant the statement recently made that radium will replace the knife in the treatment of cancer. In the fight against cancer, books with an optimistic point of view, such as this, are not always helpful.

The Nervous and Chemical Regulators of Metabolism. Lectures. By D. Noel Paton, M.D., B.Sc., Professor of Physiology in the University of Glasgow. Price, $2 net. New York: The Macmillan Company, 1913.

The author in this volume gives a brief but comprehensive review of the present knowledge of the so-called "ductless glands," the endocrinous glands as he calls them. He objects, and rightly, to the customary consideration of these bodies according to their anatomical distribution in organs, and classifies them according to their seat of origin, as follows: 1. Chromaffin tissue and hypophysis from the nervous system. 2. Thyroid and pituitary from the buccal cavity. 3. Pancreas and intestinal mucosa from the intestine. 4. Parathyroids and thymus from the brachial arches. 5. Gonads and interrenal bodies from the mesothelium of the genital ridge. There is a short description of the origin and structure of the various glands, followed by a discussion of what is known of their secretory activity. The book closes with a consideration of the relation of these glands to each other and to the nervous system. It presents the subject in a concise, attractive, easily assimilable manner and can be highly recommended to the profession at large.

Diagnosis of Bacteria and Blood Parasites. By E. P. Minett, M.D., D.P.H., D.T.M.&H., M.R.C.S., L.R.C.P., Assistant Government Medical Officer of Health and Bacteriologist, British Guiana. Second Edition. Price, $1. New York: Paul B. Hoeber, 1913.

This small book was designed to furnish a working knowledge of bacteriology to students and members of the medical profession. It is not well planned for this purpose. For the man who knows nothing of the subject the descriptions are wholly inadequate, while the advanced worker should be familiar with its contents. The directions for doing the Gram stain and those for making a blood smear upon a glass slide are not those which will yield the best results. The direction to fix coverslip preparations of bacteria by passing them over a flame while holding them in the fingers needlessly exposes the worker to the danger of infection. The book is not apt to find an active demand in this country.

# Society Reports.

## NEW YORK ACADEMY OF MEDICINE.

*Stated Meeting, Held December* 18, 1913.

THE PRESIDENT, DR. WILLIAM M. POLK, IN THE CHAIR.

THIS meeting was held under the auspices of the Section of Pediatrics.

**Election of Officers.**—The following officers were elected to serve during the coming year: *Vice-President*, Dr. S. S. Goldwater; *Trustee*, Dr. William H. Thompson; *Member of Committee on Admission*, Dr. John Douglas; *Member of Committee on Library*, Dr. Robert J. Carlyle.

**Resolution Endorsing Vaccination against Typhoid Fever.**—A resolution was adopted to the effect that, since the prophylactic value of vaccination against typhoid fever had been amply demonstrated, and the Board of Health was prepared to perform this operation on request, that the Academy of Medicine approved of this measure, and advised those who were exposed to infection to submit to vaccination either by a private physician or the Department of Health.

**Medical Sociology in the Public Schools.**—Dr. MARY SUTTON MACY read this paper, in which she told what was being done for the physical welfare of the children that should be of interest to the medical profession. She stated that the public schools of New York City were of two kinds, the day elementary and high schools and the day and evening industrial schools maintained by the Children's Aid Society, with some cooperation from the Board of Education. In addition to these there were the parochial and other church schools. The Children's Aid Society also maintained the so-called Soup Schools, which provided lunches and other necessities for children whose parents were unable to care for them. The Board of Education also effected a great deal of social service bordering on philanthropy in the course of its routine work. Medical inspection in the public schools was under the Department of Health, Bureau of Child Hygiene. The corps of doctors and nurses attached to the Bureau made regular and routine inspection of the children, or of many of them as possible, and had succeeded in excluding almost entirely contagious diseases. They had in this city no serious school epidemics in these days, and the Bureau of Child Hygiene deserved full credit for this relief. Many other points were included in medical inspection, defective teeth, palate, vision, hearing, nasal breathing, hypertriphied tonsils, etc. When required, recommendations for proper treatment were made to the parent or guardian. The best results were secured where there was cooperation between inspector, school authorities, and the home, but results were not always so satisfactory where one of the trio slipped in the cooperation. The remaining fields of medical sociology were under the direction of the Board of Education, if they excepted the twenty-two elementary schools in which lunches were served as an experimental effort to demonstrate their value and effect. The Board of Education was organizing to enter on another field of work, which it was to be hoped would take effective notice of the sick teacher. Dr. Macy said she had before spoken of the demoralizing effect on a whole school of a sick teacher. The children should be guarded from sick teachers without doing injustice to the teachers. It was time that the physicians took a hand in the teacher's salary campaign for the sake of their own patients, both the pupils and the teachers. The Board of Education now maintained special classes for the blind, the deaf, the crippled, the enemic, the tubercular, and those suffering from trachoma, all of which deserved the attention and cooperation of the medical profession. They all presented medical problems in which every physician should be interested. The routine of admitting children to these classes should be known to every physician in private hospital, or dispensary practice, so that he should be able to put the parents or guardians of such children in touch with the educational people. The cooperation of the physician would be heartily welcomed, as would also his suggestions for care, treatment, nourishment, hygiene, etc. The vocational training of boys and girls deserved medical inquiry and cooperation. When a child of twelve was more mature than his fellows of the same age, he should not be compelled to stick to his books for from two to four years more before he could begin to learn a trade, and then begin without the protection and supervision that the school should give. The child not fond of his books usually formed bad habits of laggardism and truancy, and was less fitted to prepare for his life work than though he had been properly trained in some vocation from the age of twelve. The doctors should find an answer to this problem. Educators would act if the doctors would make them see. Dr. Macy said she wished to speak of her own hobby, the classes for training nervous, mentally defective and backward children, the so-called "Ungraded Classes." There were no classes for epileptics, imbeciles, or idiots, and none for the observation of nervous cases simulating amentia, neither were there any for mental defectives or morons, but all of these types of children were mixed together, and some had gotten the idea that every child in the ungraded classes was a moron or an imbecile. As a matter of fact the majority of these children were border-line cases, or high grade morons, and only time treatment and teaching would determine which was which. The time was coming when these children would be sorted out and differentiated, and the physician should enter this important field. Children applying for admission to the ungraded classes were examined, physically, not inspected, and recommendations were made that the child be taken to a specialist or a clinic as circumstances warranted. When the children were once admitted to the ungraded classes they were followed up by social workers attached to the department to see that the needed treatments were obtained. Convalescent homes were found in the country for cases in which this measure seemed to be indicated, and upon the return of these cases to the city they were followed up to see that the right education treatment followed physical upbuilding. More clinics and more physicians should be interested in actively cooperating with this department. Few physicians in clinics or out of them realized all the resources at the command of the poor of this city, and if there were more cooperation between the physician and the ungraded classes of the public schools the physicians would learn many things and the children would profit immeasurably. In closing her address, Dr. Macy made a strong plea for the cooperation of all clinics, eye, ear, dental, skin, every clinic, with the work of caring for this class of children.

**A Study of the Results of Tonsil Operations on Public School Children in New York City.**—Dr. GERHARD H. COCKS read this paper in which he summarized the results of an investigation in a series of school children whose tonsils were operated upon during the last year. This investigation was made at the request of the Visiting Committee of the State Charities Organization, and had for its object to obtain information which would warrant a request for more funds from the Board of Estimate for the care of adenoid and tonsil cases in the municipal hospitals, and also to ascertain whether any improvement could be made in the methods now employed in the schools for the disposition and treatment of these cases. Dr. Cocks stated that of 107 children examined, 17, or approximately 16 per cent., failed to have the operation performed. Of 90 cases operated upon, 9 or 10 per cent. received mutilations of the soft parts adjoining the tonsils. Of 14 cases operated upon without a general anesthetic, 13, or 92 per cent., were badly done. Of 33 cases operated upon under general anesthesia, 9, or 27 per cent., were poorly done. If the number of cases receiving mutilations were added to the number of cases badly done, both with and without anesthesia, it would be seen that 33 per cent. were poorly done. In addition there were 31 children who required further treatment for nasal conditions. It was therefore clear that the system now employed, notwithstanding its usefulness, could be materially improved. The writer concluded as follows: 1. A greater number of medical inspectors were needed. 2. School physicians and nurses should exercise more care in seeing that children referred for operation carried out their recommendations. 3. When children were referred for operation to hospital or clinics they should be sent to institutions which maintained nose and throat departments. This was to avoid attacking the tonsils when the anterior nares were at fault. 4. Hospital physicians would do well to remember that a child referred with a card from the school physician, was often sent simply for diagnosis and treatment. Such a card was not an indication that an adenoid and tonsil operation was imperative or even advisable. The hospital physician should carefully examine and decide each case on its

own merits. The mere presence of a pair of healthy tonsils in the child's throat did not necessitate operation. There should be some good indication, as mouth breathing, recurring attacks of ear-ache or tonsillitis, improper physical or mental development, etc. If operation was contraindicated, the doctor should always note this fact, together with a statement of the diagnosis and treatment, on the card provided for this purpose by the school authorities. 5. All adenoid and tonsil operations on children should be done under general anesthesia. 6. Hospitals where adenoid and tonsil operations were performed should be equipped to keep their patients in the wards for at least twenty-four hours after operation. 7. The writer begged to suggest the desirability of having a list compiled each year of the hospitals which employed general anesthesia for their adenoid operation, and carried out proper after treatment. This list of hospitals should be given to the school authorities for use in directing pupils unable to pay for private operations. A committee designated by the Academy of Medicine could be relied upon to draw up such a list on an impartial basis.

**The Child in the Tuberculous Milieu.**—Dr. MAURICE FISHBERG presented this paper which was based on the study of 217 families in which either the father, the mother, or both, were found to be tuberculous. Of 274 consumptives found among these people, only 112 slept in a separate room, and 136 in beds by themselves. Their economic condition could be summed up by saying that they were at the end of their resources, otherwise they would not have applied for relief. The children of these families offered excellent material for the study of the effects of the tuberculous milieu on children. Of the 1,129 persons comprised in this group of families, 792 were under 15 years of age. Nearly all of these children had been breast fed, only 5.5 per cent. having been fed artificially. The proportion reacting to tuberculin was not found to have any relation to the manner of feeding during infancy. The children suckled by tuberclous mothers seemed to thrive as well as others of their class; most of them, however, became infected with active tuberculosis. The weight of the infants was fairly normal, but that of the children over 4 years of age was deplorably below the normal for either children of their class. The form and shape of the chest was normal in 62.5 per cent. of the children, flat in 27.5 per cent., and rachitic in 10 per cent. The large proportion of flat chests was not necessarily indicative of tuberculous habit, as the flat chest was a common characteristic of the Jewish race. Enlarged superficial thoracic veins were found in 8 per cent. of the children, while in those in whom a diagnosis of tuberculosis was made 37.5 per cent. showed these enlarged veins, and three-fourths were unilateral. In 67.8 per cent. of the children the cervical glands were swollen, but swollen glands in the axilla, groin, etc., were exceedingly rare. Hyperplastic conditions of the nose, throat, pharynx were found in 58.6 per cent. of the children. Scrofula was rather infrequent. The external stigmata of tuberculosis, such as scrofuloderma, tuberculides, phlyctenula, glandular blepharitis, etc., were exceedingly rare among these children. Among the 692 children, 65 were found to be suffering from active tuberculosis. Of these 19 were suffering from pulmonary tuberculosis, 25 with tracheo-bronchial adenitis, and the remainder with tuberculosis of the bones, joints, etc. The mortality of children under 14 years of age in these families was rather high. While only 17, or 7.3 per cent., of all the deaths were said by the mothers to be due to pulmonary tuberculosis, in 79 instances the cause of death was unknown to the parents. Many of these were undoubtedly due to tuberculosis. The opinion of many that infants under one or two years when infected by tuberculosis did not survive the disease was not supported by their investigations. Massive infections such as were found among these children were the strongest factors in propagating the disease. Prophylactic measures against tuberculosis to be effective must be directed with a view to the protection of infants and children against massive infections such as were found among the families investigated.

Dr. T. PASSMORE BERENS said that the readers of the papers had done a valuable service in bringing this subject to the attention of the profession. The work done by the Department of Health for the benefit of the school children was work that was deserving of praise, encouragement and cooperation on the part of the profession at large. It was astonishing to learn from Dr. Cocks's statistics of the large percentage of children who had been operated upon without the use of an anesthetic. Dr. Berens considered that the practice of operating on children for the removal of tonsils and adenoids without the use of anesthetic was most reprehensible, and that it should be severely condemned at every opportunity. The practice was a horrible one; it was brutal and unsurgical, and the results usually were bad. The nervous shock to the child very frequently caused grave sequelæ; for instance, chorea, post-operative neurasthenia, and last, but by no means least, a dread of the doctor. It was astonishing to think that the children were operated upon for the removal of adenoids and tonsils with or without the use of a general anesthetic, and then within a few hours were allowed to return to their homes in the care of an untrained attendant. They should not be subjected to the dangers which this pernicious practice entailed.

Dr. S. JOSEPHINE BAKER said that she wished to endorse Dr. Cocks's conclusions in regard to tonsil and adenoid operations without an anesthetic. It had been their experience that children suffered extremely from the severe nervous shock, and that from the surgical viewpoint the operations performed without an anesthetic were not successful. Frequently children were referred for operation who had already been operated upon but who were not improved by the first operation. The hospitals were not equal to the demands made upon them. There were last year 30,000 children in the public schools who required tonsil or adenoid operations, and less than 20 per cent. were operated upon. The certificate of any physician in regard to the treatment of enlarged tonsils was accepted by the Department of Health. The Department conducted five hospitals where these operations were performed. These hospitals had been in operation for eighteen months, and about 4,000 children had been operated upon during this time. There had been one fatality. After operation the children were kept in the hospitals for at least twenty-four hours, and usually thirty-six hours from the time of entrance. Aside from the one fatality mentioned there had been no unfavorable results. It was the custom in some dispensaries to send the child home immediately after operation, and this resulted in severe secondary hemorrhage; in one instance coming under her notice the operation was followed by septic sore throat, and death. Dr. Baker expressed the hope that Dr. Cocks's paper would awaken his hearers to the fact that the dispensary was not the place for these operations, and that the hospital service could be extended so that patients unable to pay could be cared for.

Dr. ALFRED F. HESS said that Dr. Fishberg's investigation was of great interest to the community, concerning as it did perhaps 30,000 to 40,000 of its children. There were three main points raised by this paper: (1) that these children in a tuberculous environment were under weight; (2) that they did not gain weight normally; and, (3) that they reacted in large ratio to tuberculin. Dr. Hess asked what standard of weight was selected as normal. If these children were really under weight what was the cause of it? Was it due to their hereditary constitutional weakness, or to their latent tuberculous disease, or to their poor food and unhygienic surroundings? These points were important if one wished to strike at the root of the question, and to attempt a solution. It might be that these children were below par because they did not have an average amount of the proper kind of food, and did not live in quarters of average healthfulness; for it was known that the tuberculous earned less than the average wage, and therefore lived under the poorest general conditions of any of the poor in New York City. As to the tuberculin test, Dr. Fishberg had shown that the majority of these children reacted to tuberculin. They saw from the chart that 67 per cent. reacted in the second year of life. This in itself must lead to the inference that this reaction did not denote tuberculous disease, and that one could not infer from it that the children would die of tuberculosis. Indeed, the question could be asked whether this reaction did not confer immunity in later life. Dr. Hess said that it had been his experience that a small proportion of these children reacting developed tuberculous meningitis. As to the failure of these children to gain in weight: At the Tuberculosis Preventorium in the course of the past five years 1,000 children had been harbored for a period of about three months, and there had been no difficulty in making these children gain in weight, although they were nearly all the children of tuberculous parents.

There was no greater difficulty in making these children gain in weight than in effecting a gain in the ordinary child, so that in this respect he could not agree with Dr. Fishberg.

Dr. GODFREY R. PISEK said that while Dr. Fishberg had done a large and commendable work, it had been among a special class—that of dependents, of one race, and living in the tenements. These factors should be taken into consideration in studying the statistics. It was to be regretted that such work had not been done in other localities, for they were in need of just such statistics. He wished that Dr. Fishberg had told them more of his ideas regarding the mode of infection. Was the infection enterogenous or aerogenous? In studying these families it should be remembered that when the father became tuberculous the mother became the bread winner, and the children were left in the father's care at home, and close to the source of infection. In this respect the children differed from the general type of child. In Germany the percentage of infections was given as 80 per cent. of those exposed; he had always been under the impression that this percentage was higher than ours, and was glad to learn the statistics. Dr. Fishberg had not told them much about the physical signs; it would be interesting to know what type of physical signs these children presented mainly. He hoped that such physical examinations would be made, and a report presented. The theory had been confirmed that adult tuberculosis was latent tuberculosis in the child, and while they did not see the signs in the prenatal state, and during infancy, they saw them in what might be called the paratuberculous conditions of later life. A lowered resistance predisposed to these paratuberculous conditions, and was certainly the result of living in a tuberculous environment.

Dr. R. OTTOLENGUI said that he was a dentist, practising more particularly orthodontia, and had been asked to discuss Dr. Cocks' paper. He presumed that he had been asked to come here to tell them that the claims of the orthodontist were exaggerated. If it was true that the Department of Health was finding that the results of tonsil and adenoid operations were not always satisfactory it was equally true that the dentist was finding the same conditions. The time was when the dentist asked the parents, "Has this child been examined for adenoids?" Now they ask, "Has this child been operated upon for adenoids?" The answer frequently was heard "Yes, two or three times." Dr. Cocks had mentioned mouth breathing and the high vault as though they were stigmata. What did high vault mean? Did it mean high from the floor of the mouth or narrow in proportion to the width of the arch?

The statement had been made by dentists that they lowered the vault by pulling the vomer down. There was not a scintilla of truth in this statement; those who made it had good intentions, but they were mistaken. There was nothing in the apparatus employed that could lower the vault. Another claim sometimes made was that more breathing space could be given by opening the median suture and this was equally an error. Radiography had shown them their mistake in this respect.

Dr. JOHN E. MCKENTY said that in his work he met with many cases in which operations on the tonsils had not been successful, but he did not suppose conditions were as bad as had been stated. Children should be sent to hospitals properly equipped to make examinations for nasal obstructions as well as to care for abnormal conditions of the tonsils. In children who had suffered from enlarged tonsils and adenoids for a considerable length of time there was usually hypertrophy of the inferior turbinates. This condition had been recognized in the clinics abroad, and they now made it a routine practice when operating on the tonsils to remove a small portion of the inferior turbinates. One cause of mouth breathing and of bad results in these operations was faulty occlusion, and he was thoroughly in accord with the work that the orthodontists were doing in their endeavor to correct this defect. Again, it often happened that a child after operation continued to be a mouth breather simply because he did not know how to breathe properly. The proper method of breathing was now being taught in some of the clinics, and this had been brought about through the influence of the orthodontists. The speaker said that he saw some instances in which only a part of the tonsil was removed and the cut surface became cicatrized and obstructed drainage, and thus the condition after operation became worse than before. The modern operation was a major operation, and should be in the hands of an expert.

As to the care of these children, it should be remembered that there were only forty or fifty beds for such cases in the city hospitals, and who was to pay for the work? If they were cared for by the city hospitals the city would lose about two dollars on every case.

Dr. JOHN WINTERS BRANNAN said that he had been interested in all the papers, but especially in what Dr. Cocks had said in regard to anesthesia in tonsil and adenoid operations. Six or seven years ago he had been impressed by the cruelty of these operations at Bellevue, and had been instrumental in having a ruling passed forbidding the performance of these operations without an anesthetic. This operation was now a major operation, and should be conducted as such. Only last week he had heard of two places where the operation had been performed without an anesthetic. In one of their hospitals a surgeon was said to have performed a tonsil operation three times without using an anesthetic. He had boasted that he could do the operation in sixteen seconds; all he seemed to think of was the speed. When the question arose as to whether this offender should be disciplined he stated that he had only removed the adenoids. This affair brought out the statement that there had recently been a change of opinion as to the necessity of an anesthetic in these operations, and that there were authorities who believed that some of these operations could be performed without the administration of a general anesthetic. He was glad to have heard what had been said this evening, and hoped it would have its influence on the trustees who were dealing with this affair. It should be insisted upon that these operations should not be performed in dispensaries and out-door clinics, but only in such institutions as had hospital facilities for caring for these patients.

Dr. FISHBERG, in closing the discussion, said that Dr. Hess had asked a very proper question. In making comparisons of this kind the race factor must always be considered. In his study he had compared the children in the tuberculous milieu with those of the same race and stock measured in the public schools in the same neighborhood. As to whether the children who made an active response to the tuberculin test were in danger of their lives, he wished to say that the infection might be massive or mild. The child with mild infection might become immune to the disease, and not only not succumb to it, but might be proof against reinfection. Those who received a massive infection during the first or second year had probably succumbed, and those who survived might carry a latent lesion which might flare up at puberty.

Dr. L. E. LA FÉTRA asked if he might reopen the discussion in order to ask a question. He said that he wished to ask Dr. Cocks if, when he spoke of operations on adenoids and tonsils without a general anesthetic, he meant that in all cases where it was necessary to remove adenoids, even if no tonsil operation was required, a general anesthetic should be administered.

Dr. COCKS replied that he considered it necessary to employ a general anesthetic for the removal of adenoids if one expected to do a complete operation.

**Election of Officers for Section on Pediatrics.**—The Section on Pediatrics elected the following officers for the year 1914: *Chairman*, Dr. William P. Northrup; *Secretary*, Dr. Royal Storrs Haynes.

---

SECTION ON OBSTETRICS AND GYNECOLOGY.

*Stated Meeting, Held November* 28, 1913.

DR. WILLIAM M. POLK, IN THE CHAIR.

**Radiotherapy of Uterine Fibroids.**—PROFESSOR KROENIG of Freiburg, Germany, made this address. He declared that as yet one could not speak conclusively on the results of radiotherapy as the whole subject was still in its infancy. A discussion of these new methods was, however, of the greatest advantage; the universal discussion that took place on this subject at the International Congress at London had been of the greatest advantage in extending their knowledge. He had learned much from the Americans, especially from Dr. Abbe, who had contributed so much to the elucidation of the problems of radiotherapy. Naturally the discussion of the Roentgen ray treatment of benign and malignant growths would have to be separate, as the two kinds of growths responded in such different ways to radiotherapy that it was quite impossible to discuss

them together. Their experience with benign growths had been sufficiently extensive to enable them to draw rather concise conclusions. The Roentgen rays were well adapted to the treatment of fibromyomata and one could undertake their treatment with certainty as to the result if a combination of the Roentgen rays and mesothorium and radium were adopted. The speaker particularly emphasized the point that they differed from others in the use of radiotherapy in that they had been giving the largest possible doses. This high dosage was not necessary, however, in every case. Large doses had not in any case produced harmful results. In cases where small doses were employed, if the condition proved refractory to such treatment, much valuable time was lost which could have been saved by immediate recourse to the larger doses. In women over fifty years of age there were few cases which did not respond to small doses. The small dose sometimes had the disadvantage of increasing the hemorrhage and causing it to last longer until a condition of acute anemia threatened the life of the patient. They began to use the large doses something over three years ago and had found no case which did not respond to this treatment so far as the production of amenorrhea was concerned. Their series of cases numbered 350, and many of these had been watched for several years, so that they could speak with certainty as to the permanence of the results. The first effect of the treatment noted was a diminution of the hemorrhage and a decrease in the size of the tumor. In cases in which the growth was large they seldom attained their object and recurrences were frequent. Where enucleation of the tumor was possible this measure was preferable, as it preserved the function of menstruation and the possibility of conception, to radiotherapy or extirpation of the uterus; but radiotherapy was better than extirpation of the uterus and they had abandoned operative treatment in all cases except those rare instances where enucleation was indicated. Radiotherapy did not threaten life as did operative procedures. Again cases for operation had to be selected, the bad operative risks being rejected. There was no such restriction for radiotherapy. With radiotherapy the after effects were much less distressing than after myectomy or hysterectomy. It could not be denied, however, that radiotherapy had its disadvantages. First, the duration of treatment, five to eight sittings at intervals of eighteen days being required, lengthened the duration of treatment to three or four months. It should be remembered, however, that the patient could work during the entire time of treatment. The duration of treatment might be shorten d by the addition of the mesothorium and radium treatment. It was very important that the patient should have two or more treatments after the amenorrhea had been established. The skin lesions which were formerly so frequent in Roentgen ray work were, with the modern technique, no longer encountered. A filter was used which eliminated the *alpha* and *beta* rays, which were less penetrating and responsible for the surface lesions. The highly penetrating rays of mesothorium and radium might be applied in three ways; either the application might be made to the abdomen, or a filtered capsule might be introduced into the vagina, or a capsule might be introduced into the uterus. When the latter method was employed smaller doses would be required, but with this method there might be a rise in the temperature. Though no serious consequences had been noted by this method, there had been edema of the cervix in two cases. The speaker said that his preference was for the treatment *per vagina*, as this method had the advantage of rapidly producing amenorrhea. The treatment was much more successful with small than with large growths. This treatment had been employed in prostatic growths in three instances, in one of which the growth rapidly separated from its capsule and the hypertrophy decreased so that the change was easily perceived by the sense of touch, the second case was only partially improved, and the third was still under treatment. Goiters had also shown a recession under this treatment. In many benign tumors it would take the place of operation, but such a statement could not be so conclusively made of malignant growths. The treatment of carcinomas by the Roentgen rays presented many difficulties. The growths were apt to be too deep seated and too far from the anticathode, so that there was a great loss of rays; radium and mesothorium could be brought near the carcinomatous tissue. While permanent results had been secured in many conditions, this could not be claimed for the deep-seated carcinomas in a sufficient number of cases to warrant the expression of any great claims in this class of cases. The speaker said that they had treated in all 254 cases, 150 of which were treated therapeutically, while the remainder were treated for the prevention of recurrence. Of the 150 cases treated therapeutically, 140 were treated with mesothorium and radium, while in the other ten cases the Roentgen rays alone were used. Of these 140 cases in which the combined treatment by the Roentgen rays and mesothorium and radium were employed there were three groups: 1. Those in which the carcinoma had not spread from the primary focus. 2. Those in which there was a new growth beyond the primary focus but in which operation was still possible. 3. Those cases in which metastases had formed. In the latter group they had not succeeded in effecting a single cure, though the disease had been checked in some instances. In most of the second group it had been impossible to effect a permanent cure, but there were a certain number of cases which responded well, there being retrogression not only in the tissues but in the glands. The cases in which the carcinoma had not spread beyond the primary focus were particularly suited to radiotherapy and mesothorium treatment. In a number of these cases they had been able, after a course of treatment, to demonstrate that cancer cells were no longer present. Of 64 cases treated for the prevention of recurrence, 45 were treated with unfiltered rays and 19 with partly filtered rays; of the 45 treated with unfiltered rays, 23 died of carcinoma, while the 19 treated with filtered rays were still alive and without recurrence. Sufficient time had not yet elapsed to state that some of these cases were permanently cured. Of those treated by partly filtered and partly unfiltered rays, 60 per cent. were without recurrence at the end of one year. Dr. Kroenig said that from these results it could be seen that they could not expect too much from this method, but when one considered the high mortality in cancer of the cervix one realized that if even a small part of these were saved it would be worth while. The most striking results from the Roentgen rays and radium and mesothorium were obtained in fibromyomata, small benign growths and primary carcinoma. Professor Kroenig gave a lantern slide demonstration showing specimens before and after the application of radiotherapy.

**The Technique of Radiotherapy.**—Professor Gauss of Freiburg, Germany, presented this phase of the subject. He stated that the use of the Roentgen rays had long been confined to pathological conditions on the surface of the body as attempts to use the more penetrating rays had resulted in surface burns from the less penetrating rays. Now they had learned that by the use of metal filters they could prevent the passage of the softer rays. In their experiments on tadpoles they had learned that the filtered rays checked the growth and killed the tadpoles. They obtained a deeper action with the filtered than with the unfiltered rays provided they could get enough of them. Results were dependent upon the concentration of the dose into a short time. If the same dose that was concentrated into a short period was given over a long period of time it might even cause the growth to increase in size. The usual dose was five, seven, or ten milliamperes. By giving large doses in a short period of time almost all the patients to whom the treatment was applicable were cured. The average case of fibromyomata required from three to four months in order to effect a cure. The average total dosage in these cases was one to two thousand milliamperes. In some instances they had been able apparently to influence hopeless cases to such an extent that cancer cells no longer existed where before they had been growing most profusely. With the Roentgen rays alone they did not get results at any depth, but with the radium and mesothorium they were able to reach the deeper tissues. The *gamma* rays of radium and mesothorium could be applied successively to different sections of the diseased area. The dose contained in each capsule was about 200 milligrams, and this was enclosed in a metal filter. Where space was a consideration gold had been used in place of lead, as, for instance, in the uterus. In confined spaces the secondary rays were sometimes kept off by gauze or rubber. Treatments were repeated every three weeks until there was no trace of cancer. Then prophylactic treatments were given occasionally at intervals of perhaps three months. In general surface work the Roentgen rays were substituted for mesothorium as they had the

advantage of covering a larger surface and were cheaper. Mesothorium was employed for the malignant growths. Myoma of all sizes and occurring at any time of life could be dealt with by the Roentgen rays, and if results were delayed the vaginal mesothorium treatment was added and seemed to hasten the cure considerably. In applying the Roentgen rays the abdomen was divided into twenty or thirty sections of about four square centimeters each, and other parts were protected. Each section was exposed in turn to the Roentgen ray tube which was enclosed in its metal casing. The tube was lowered until the anticathode was from twelve to twenty centimeters from the surface of the exposed area. The tube was excited with from five to ten milliamperes and should always be of the same degree of hardness, and for the penetrating rays only a very hard tube was used. The dose consisted in five to ten milliamperes interrupted from fifty to seventy times per minute. Intervals of eighteen days elapsed between the treatments and amenorrhea was produced in from four to eight sittings. The point could not be too strongly emphasized that the treatments should not be too few. Kroenig had also used a platinum capsule.

Professor GAUSS exhibited capsules designed for introduction into the vagina, rectum, larynx, and esophagus, and for external application. He said that the application of these capsules seemed very simple, but that such was not the case; no one should attempt to use such treatment without much instruction and experience.

Dr. GEORGE P. PFAHLER of Philadelphia said that no doubt they all felt as he did that a debt of gratitude was due Dr. Kroenig and Dr. Gauss for having shown such excellent results and the method by which they were produced. There were a few points which he wished to emphasize. Dr. Kroenig and Dr. Gauss had treated ten times as many patients as he had, but his experience had extended over a longer time. They had all used the cross-firing method, but they had not used the large doses suggested this evening. In his work he had been accustomed to divide the area to be treated into four instead of twenty or thirty parts, and consequently he had given but one-fifth or one-tenth the dose, but his results had been more than one-fifth or one-tenth as good. He believed that they should take advantage of as much power as they could. They, too, had developed a filter method. Seven years ago he had demonstrated that the backs of rabbits could be protected by leather, and since that time they had been using filters. Dr. Pfahler said he had understood that the subject to be discussed was malignancy and he had prepared a lantern slide demonstration showing his results in some forms of malignant disease extending over ten years or more. These slides illustrated the results obtained by the use of the Roentgen rays on round-celled sarcoma involving the upper portion of the fibula, on an osteosarcoma with fracture on the side of the ileum, on osteosarcoma of the giant-celled variety, and on orbital sarcoma. The fact that these patients had been without recurrence for a number of years gave proof of the permanence of the cures. In one instance of sarcoma of the face there was a marked dermatitis of the opposite side, which was a very graphic illustration of the penetrating power of the rays.

Dr. L. G. COLE, after expressing his gratitude to the speakers, of the evening, said that he could not speak from a gynecological standpoint, but the cross-firing, which, although used before Dr. Kroenig and Dr. Gauss had employed it had been so emphasized by these men that they were deeply indebted to them for the development of this method. It was necessary in deep therapy to use a high vacuum tube and to keep the tube at that vacuum. These points should be recognized and emphasized. The work of Dr. Pfahler was very remarkable and every time he saw it it seemed more graphic. The case that he related which grew worse under inefficient treatment and which so quickly responded to correct treatment emphasized the importance of having as thoroughly competent men to do röentgenological therapeutic work as of having competent men to do *x*-ray diagnostic work. When this kind of work was done with the skill shown this evening he prophesied great success for röentgenological therapeutics in the next five years.

Dr. ROBERT ABBE declared that he had been almost startled by the brilliancy of the expositions of the evening. They certainly were indebted to the speakers for their enthusiasm and their moderation, and it should be left to them to continue their investigation and to tell what could be done by their methods. Dr. Pfahler's demonstration of what he had accomplished in the treatment of sarcoma by the Roentgen rays well filtered made it evident that here was a great field for work and that they had only scratched the surface. In regard to the uterine work, Dr. Abbe said he thought this was a very difficult branch of radiotherapy; he had not pursued it elaborately, but had practised the uses of radiotherapy in the heretofore uncontrolled diseases of this type. There was here and there a case where lasting benefit was obtained, but this occurred usually in the less malignant conditions. The pathology of cancer was unknown, but they knew that there were many grades of malignancy, and what would effect a cure in one grade would not do so in another. Cancer as a growth of the weak cells, the less resistant cells, and hence the cancer cell could be overcome by forces that would not destroy the normal cells or the skin. The fact that papilloma of the vocal cords could be destroyed by radiotherapy while the vocal cords themselves were uninjured was a striking illustration of the susceptibility of the weak cells and the resistance of the normal tissue. The cancer cells were not only weak but they were of varying grades. Fibroids were amenable to radiotherapy in many instances, especially the mural types. The speaker cited two cases successfully treated by radiotherapy, one dating back to 1905, which he had recalled as Dr. Kroenig and Dr. Gauss were speaking of the large doses and of Roentgen rays and of their repetition. One of these cases received but one treatment, one-hundred milligrams of radium in a tube being placed in the body of the uterus. It was left in less than twenty-four hours. The hemorrhage stopped, and there was a gradual recession of the growth until at the end of five years but a small remnant remained. With many tumors it was best to give the correct dose and then let the patient alone; if one kept on irritating the growth it got worse, so it seemed that they had a vast deal to learn about dosage, and he would not be surprised if one massive dose and a long abstinence from treatment would not be equally efficient in *x*-ray work. This was not work for the general practitioner at the present time; he should let it alone and not make a fake of it. This field of work should not be entered upon unless there was a large amount of radium at one's disposal and a large number of cases available, under such conditions that they could be watched, and where there were opportunities to compare the results with those from a large number of surgical cases. The work should also be confined to those who could work without regard to financial reward, and if these precautions were carried out he felt confident that they could add much to their present store of knowledge.

Dr. SINCLAIR TOUSEY said it had been a great pleasure to listen to the distinguished guests of the evening who had been largely instrumental in spreading the knowledge of the curative effect of the *x*-ray in uterine fibromyomata. It was important, however, that no one should carry away the mistaken idea that their method robbed the *x*-ray of the danger of over-exposure or produced a radiance which might be safely applied by one unskilled in deep radiotherapy. His own experience corroborated the fact of the curative effect, but led him to feel that the technique described should not be undertaken lightly by anyone possessing an *x*-ray apparatus, but not especially experienced and skilled in the treatment of deepseated lesions. He agreed with the essayists regarding the advantage of filtration, but it would be a grievous error, and lead to most disastrous results, to interpret this fact as indicating that the rays which penetrated to and profoundly affected deep tissues were without effect in the superficial tissues which they first traversed. This effect was present, and was exceedingly destructive in overdoses. In his practice he carried the exclusion of the less penetrating rays one step further by using a generator of his own suggestion which sent a constant current of suitable voltage through the *x*-ray tube, and so produced approximately homogeneous *x*-rays of the desired penetration. He used filtration as an additional precaution. He personally disapproved of the short distance used by the essayists. The economy of time was unquestioned, but to produce an effect upon the tissues four inches below the surface with the anticathode five inches above the surface, the skin would receive about twice the dose to which it would be exposed if the anticathode were thirteen inches from the surface with an exposure long enough to produce an equal effect at a depth of four inches. Roentgen ray ulcers of the intestine had been

reported from Germany as a remote effect of the technique under consideration. No man should apply a radiance for treatment or examination unless he knew how to measure its dose and had calculated its dose for the distance at which it was proposed to place the tube. Anything else was like giving a man a hypodermic of strychnine without knowing the strength of the solution.

Dr. ARTHUR F. HOLDING said that this meeting had given him great pleasure not only because of the epoch making work shown by Professors Kroenig, Gauss, and Pfahler, but also because of the opportunity of witnessing men who were not primarily roentgenologists become enthusiastic over the results obtained by the *x*-rays. That the gynecologists, Professors Kroenig and Gauss, drawing their conclusions from such a large number of cases, and after such painstaking research, had become more enthusiastic about the *x*-rays, mesothorium, and radium than roentgenologists would dare to become in open meeting, was a rare tribute to the efficacy of these agents. The total number of cases treated by Professors Kroenig and Gauss, 350 at the present time, was greater than the combined total of all the cases treated by the men whose work antedated theirs. The reasons for this were the ability, character, and attainments of Professors Kroenig and Gauss, and the fact that while being surgeons they were progressive enough to recognize and make use of these new agents; because of their improvements on the technique of the application of these remedies and the convincing reports of their results, and, perhaps, because they had control of their cases. This was a clear indication of the brilliant results that might be expected in all specialties when new agents should be carefully adapted to the special problems of each specialty by men who were cognizant of these conditions. Publicity should be given to this work that it might be generally known what might be accomplished with large doses of Roentgen rays. This would result in a great increase in the number of cases treated and along with the successes there would come a new era of *x*-ray calamities, therefore it could not be insisted on too emphatically that all *x*-ray treatment was not good *x*-ray treatment just as all surgery was not necessarily good surgery. Roentgen therapy was entirely dependent upon technique.

## MEDICAL ASSOCIATION OF THE GREATER CITY OF NEW YORK.

*Stated Meeting, Held October 20.*

THE PRESIDENT, DR. REYNOLD WEBB WILCOX, IN THE CHAIR.

**Tuberculous Patients Treated by a Special Method and Plan of Control.**—Dr. C. AM ENDE explained his employment of the Moro reaction as a means of diagnosis and his treatment by the internal administration of creosote and pills of quinine and iodoform, as already described by the speaker in the MEDICAL RECORD, and said that the dispensing of the remedies by the physician himself assured the advantage of control over patients. He then gave reports of a number of cases and presented three of the patients. The first of these was a girl ten years old who was brought to him in November, 1912, on account of a hacking cough. She was pale and emaciated, but the physical signs did not show any positive evidence of tuberculosis. An application of the Moro salve, however, gave a strong reaction; producing an intense, florid, almost pustular eruption. She was placed upon his special treatment, and soon began to gain in weight and improve in every way. A second inunction in January was followed by a much finer reaction, and at the present time she was entirely well. The second patient was a little boy who had had chains of enlarged glands on both sides of the neck and in whom the Moro test had given a very distinct reaction. Under the treatment his general condition had greatly improved, and at present but a single enlarged gland remained. The third was an adult male patient who had first come under observation about a year ago, when he was in quite a critical condition and the prognosis seemed very bad. Aided by some rest at the seashore, the improvement in his case had now gone so far that he was enabled to resume his occupation, which was that of a paper hanger. In addition to the pills and creosote, he was now receiving injections of tuberculosis vaccine. This had previously failed, both in England and Germany, when used by itself, but it was possible that in combination with the internal medication it might prove of service. In concluding his remarks the speaker said that if people in general could be made to understand that a person might have pulmonary tuberculosis entirely unknown to or unappreciable by himself or his friends, and thus be induced to consult their physicians concerning anything unusual which they noticed in their state of health, considerable reduction in the mortality from this disease might result.

**The Theory and Treatment of Diabetes.**—Dr. WILLIAM E. FITCH said that about one year ago he began a clinical investigation on the further study of diabetes mellitus, more particularly its control by dietotherapy, and to a card requesting information from the profession as to the propriety of allowing a liberal starch allowance, which was inserted in more than a hundred medical journals, he received over a thousand replies. While 57½ per cent. agreed with von Noorden that "the best treatment for the diabetic is the food containing the greatest amount of starch which he can have without harm," the consensus of opinion from these correspondents was that the present methods of treatment were unsatisfactory to both patient and physician. Laboratory work upon diabetes during recent years and a more careful study of its metabolic disturbances had taught us many new facts, particularly from the dieto-therapeutic viewpoint, which had been thought to be the true one but in the light of later research had been materially modified; and von Noorden, one of the best known authorities on this subject, had stated that opinions which had prevailed for two decades concerning the theory of diabetes could to-day be no longer maintained. For the sake of convenience the speaker referred to three types of diabetes; cases due to lesions of the fourth ventricle, those due to metabolic disturbances of the liver and alimentary canal, and those due to pancreatic disturbance (atrophy of the islands of Langerhans). Cases of the first class, while rare, were often puzzling on account of the absence of accompanying brain symptoms. Those of the second class, the most common, were of two broad types: (a) The stout patient, very fond of food and usually termed a "high liver," who was inclined to a sedentary life; (b) a person of ordinary build whose urine was free from uric acid sediment, but who suffered from skin complications. Patients belonging to the third class suffered from great thirst, voracious appetite, and marked emaciation, and excreted large quantities of urine loaded with sugar. He did not wish it to be inferred, however, that he believed the diseased process to be confined to any one organ, for no organ worked for itself alone. It depended upon processes taking place in other organs, together with the products of its own activity which influenced the functions of other organs. These products might be ferments stimulating decomposition in the blood or hormones regulating activity of the cells. Recent researches had tended to confirm the importance of the part played by the internal secretion of the pancreas in carbohydrate metabolism, and it had been found that many organs such as the thyroids, parathyroids, adrenals and the glandular lobe of the hypophysis influenced not only the metabolism of protein and fat, but also exerted a special modifying effect on the behavior of carbohydrates in the organism. The influence of the nervous system on carbohydrate metabolism had been recognized since the days of Claude Bernard, and there could be no doubt that nervous influences entered into the pathology of many cases of diabetes. A number of toxic influences possibly acted in a similar manner. From what had now been said it would be noticed that at the present time there was a tendency to revert to the doctrine that over-production of sugar is the main cause of diabetes. This view was now held by a number of eminent observers, including von Noorden, who considered that the hyperglemia, and consequent glycosuria, is due to an excessive output of sugar by the liver, and that this may arise from excessive stimulation or impaired inhibition. The stimulus to the liver might come from an excess of carbohydrate food, as in alimentary glycosuria, from an increased call by the tissues, from overfunction of the adrenals, etc., or from the central nervous system through the medium of the chromaffin system. Impaired inhibition might arise from suppression or impairment of the functions of the pancreas or from interference with the controlling action on that organ of the thyroid or hypophysis. In some cases also there was probably a primary anomaly of the liver cells themselves. The views at present held with regard to the interaction of the ductless glands and their part in the production of diabetes were to some extent theoretical (especially so as regards the chromaffin system), but they correlated in much more satisfactory manner than had previously been possible the experimental data which had accumulated as to the effects of these

organs on carbohydrate metabolism, and brought into line the known facts in the etiology of diabetes. With a better understanding of the theory of the origin of the disease, and a more thorough study of the metabolism of the diabetic, there had come a reaction from the severe restriction regarding the use of starch foods, favoring a more normally balanced diet. Metabolism was the all-important factor in the maintenance of life and health, and in the process of digestion starches were first of all converted into alcohol before the work on the rehabilitation of the organism could begin. We knew that any food became an irritant when taken in excess above a legitimate demand; therefore carbohydrates containing starch (untreated), given in great amount to a diabetic, would cause an irritant effect upon the sugar-producing organs, and as a result the patient would suffer from glycosuria. To the question: Why does a diabetic excrete sugar in his urine? the answer was: Because of faulty carbohydrate metabolism; the patient is not able to convert the sugar into alcohol in his system. The reason for this was at present unknown. This much was certain, however: if carbohydrates were withdrawn from his dietary the patient would feed on himself until all the fat stored in his system had been consumed, and then he would die. We could not live and have our being without alcohol in our systems, because, as had been stated, all starches must be converted into alcohol before they could yield their energy to the system, and a certain amount of alcohol was necessary for the conversion of nitrogenous food into tissue-building material. We recognized that diabetes was primarily a disturbance of nutrition in which the function of utilizing carbohydrate foods was more or less completely impaired, but as it was a malady subject to varied complications, it presented a difficult problem in treatment. There was no disease with which he was conversant which necessitated such a careful balancing of all the details of each individual case. The metabolic powers, the functional capacity of the liver and pancreas, the condition of the alimentary tract, the state of the nervous system, and the environment of the patient must be severally and collectively considered in forming a conclusion as to the advice that should be given for his daily life in the future. Winnowing the chaff from the good grain on this subject, we found that diabetes in a person free from complications was amenable to satisfactory treatment; in fact, easily curable in proportion to the accuracy and persistency of the treatment, as well as the honest cooperation of the patient. The newer researches had taught us that the manner in which the carbohydrates were allowed was a matter of the greatest importance. It was therefore the duty of the physician to study his patient carefully in order to determine just the kind of carbohydrate he could tolerate and the method of preparation best suited to his condition, so that he might be allowed the greatest amount possible without increasing the output of sugar. For the general purposes of work, warmth and nutrition all three types of foodstuffs, proteins, fats and carbohydrates served well, though the muscular tissues were most specific in their requirements; having a predilection for sugar as their immediate source of energy. It was necessary, therefore, that sugar should always be available for the purpose, and the liver fulfilled this function. It was a well-known physiological fact that all the carbohydrates of food were converted into sugar in the intestines, and carried to the liver as such; but a special protection existed for the prevention of an excessive flow of sugar into the blood after a large meal of carbohydrates. The liver took up the sugar as it arrived and stored it in its cells, where it was instantly changed into an insoluble form known as glycogen, to be used as a reserve material. This storage of carbohydrates as glycogen, and the further change of glycogen into sugar, was not all the work performed by the liver. As human beings consumed various kinds of foodstuffs, it was compelled under certain conditions to make sugar from albumens, fats and proteins also. Various carbohydrate cures had been recommended, such as the "oatmeal cure," by von Noorden, the "rice cure," by von Duhring, and the "potato cure," by Mosse, but experience taught that none of them could be relied on. The best, perhaps, was the oatmeal cure, which, however, according to Blodgett of Boston, could be used only at stated periods, "carbohydrate days," when it was advisable that it should be cooked for about seven hours. After referring to the dangers of a starch-free diet, and quoting a number of authorities on this point, Dr. Fitch said that he had tried the rigid starch-free diet, only to be disappointed, and had prescribed the various carbohydrate cures in different types of the disease without satisfactory results. He had also used gluten foods and gluten flour, and had come to the conclusion that the only virtue in these products depended upon the large percentage of starch they contained. Unfortunately, pharmacology had not provided any drug which acted directly on the sugar-forming function of the liver. Therefore, properly selected diet was more efficient than any drug or combination of drugs in the treatment of diabetes, and offered the most rational promise of relief or cure. It was, indeed, the sheet anchor of our therapy. During the past two years he had treated a series of patients with a carbohydrate food manufactured from wheat and barley cereals, the grain being ground on the old-fashioned Buhr millstone, the finished flour containing all the natural starch and salts. After being ground the flour was subjected to a certain degree of heat for a specified time, and this produced changes in the envelope of the starch atoms which facilitated digestion and assimilation. He believed personally in allowing diabetics carbohydrate, together with nitrogenous food, sufficient to build up and maintain the animal economy; but starch and nitrogen *per se* meant nothing toward sustenance until the economy had converted these elements into tissue-building material. Among the many advantages of starch-treated foods was the fact that they indirectly facilitated the absorption of other foods, especially carbohydrates of every kind, on account of the apparent "inducement" they seemed to hold out to the enzymes of the intestinal tract to assume their full amylolytic function promptly and thoroughly. He had treated a large number of cases of diabetes of various types by prescribing these starch-treated foods, to the exclusion of all other starch foods, and had been much gratified to see the percentage of sugar in the urine gradually diminish and finally disappear.

**Diabète Azoturique of the French.**—Dr. Anthony Bassler first drew attention to the scarcity of literature on this subject, stating that such as was obtainable had been contributed by French and English authors; no article having appeared by any writer on the western hemisphere. The classification which he suggested, under the term azoturia, was: (1) physiological azoturia; (2) azoturia simplex; (3) azoturia gravis; thus eliminating the confusing term, diabetes, to which the condition in its medical form might be considered somewhat allied, and giving to us terms applicable to practical medicine. In physiological azoturia an increased oxidation took place for some reason in the body, and consequently an increased output of nitrogen-bearing substances in the urine occurred. Such augmented oxidation might be due to the effect of such conditions as cold, excessive exercise, powerful emotions, physical pain, prolonged digestion of protein foods, and repeated pregnancies. The term might also be applied to certain abnormal conditions of the body, such as continued fever and some of the acute lesions and functional disturbances of the nervous system, though these were only relative. In azoturia simplex what characterized the affection was the absence or mildness of constitutional symptoms, its more acute or limited course, the fact that polyuria was absent or of only slight degree, and an output of urea and the phosphates only moderately above normal. It was met with in both children and adults, but mostly the latter. Emotions, traumatism, suffering from painful affections, and excessive indulgence in food and alcohol were factors in its production. A case of this simple form might continue for a long time, and finally pass into the grave type. In the majority of instances, however, if the condition was recognized and was properly treated it subsided after some weeks. What might be considered a case of azoturia simplex should make one hesitant in regard to the prognosis, for while the diagnosis of such a degree of the condition could be based upon the severity of the symptoms and the course under treatment, a progression might nevertheless take place. Azoturia gravis was the most important form. It was met with principally in male adults between the ages of 40 and 45 and those suffering from lesions of the brain or spinal cord, syphilis, painful affections, chronic alcoholism, and over-indulgence in nitrogenous foods. It was debatable whether the condition is brought about by a disturbance of the nervous system, as suggested by Bouchard, or a metabolic disturbance of the body in general. Argument was presented to show that the symptoms are due to constitutional causes, the nervous disturbance being consequential. The speaker believed that it was of hepatic origin and that the pancreas also played an important etiological part; for we knew that the pancreas has to do with the transformation of the nitrogen bodies, as well as the carbohydrates. The symptoms were progressive emaciation, exaggerated appetite and thirst, various neuralgias, disturbances of the special senses, loss of muscular strength, hemorrhage of the retina and vitreous, abundant sweating, and cachectic edema. To-

ward the end phthisis and gangrene might be added. During the course of the affection the tongue was usually pale, pasty and foul, with red and irritable edges. An increased craving for food might alternate with complete anorexia. As the case progressed anorexia might alternate with polyphagia, and there was usually pain in one of the loins or legs. Boils, smaller than those seen in diabetes mellitus, might occur. The principal symptom upon which the diagnosis of this and the other forms was made was the azoturia; which required the examination of a 24-hour specimen. The amount of urine excreted was usually about five liters, but was sometimes as much as twenty liters. It might be light or dark in color. It was of a very pronounced acidity, and the specific gravity often exceeded 1040 or even 1050. It became quickly ammoniacal upon standing, because of the amount of nitrogen-bearing substances being broken down by bacteria. There was no albumin or glucose in the urine, although in the beginning an albuminuria might be noticed. There might be a low specific gravity; in which case the symptoms were generally in the central nervous system and only mildly constitutional. The main feature of the urine was the azoturia, by this being meant an excess of urea, uric acid, and nitrogenous extractive substances. In the course of 24 hours the urea output was between 40 and 150 grams (normal amount, 25 grams, or, according to the latest estimate, 16); the uric acid reached 9 grams (normal amount, 0.7 gram); and the nitrogenous extractives of creatinin and uroxanthin reached or exceeded 70 grams. The chlorides and phosphates were also in excess; the former usually ranging between 15 and 30 grams (normal amount 13 grams), and the latter, represented in phosphoric acid, being between 5 and 6 grams (normal amount, 3 grams). In the absence of facilities for making the nitrogen partition, urea might be taken as the diagnostic index of the condition. Of course, the accurate methods of analysis of Morner-Sjovist and of Folin were advisable, but when these were not practicable, the ordinary urinometer, with multiplying the quantity of nitrogen obtained from 1 c.c. by the number of cubic centimeters of urine voided, was sufficient for clinical purposes. The presence of a moderately increased amount of urea suggested the simple form, while the presence of a large amount, with the characteristic general symptoms, pointed to the grave form. The Ehrlich aldehyde reaction, which was invariably positive in azoturia, should also be noted. Dr. Bassler advised that in all cases of diabetes mellitus, phosphatic diabetes, and even diabetes insipidus urea estimations should be made, since the case under observation might be a mixed one, and when glycosuria was present with azoturia it was much more serious. It might be mentioned, he said, that while diabetes mellitus was common, phosphatic diabetes (or, better, phosphaturia) was less frequent, and azoturic diabetes (or, better, azoturia in the forms that he had classified it) the rarest of all. It was important to bear in mind that azoturia might coexist with diabetes mellitus; in which case the prognosis was much worse than when either occurred alone. The treatment suggested that more urea estimations in urine should be made in a general routine way, since by this means all cases of the simpler forms would be detected sufficiently early and could be treated successfully. The condition once established, the treatment consisted in a judicious management to prevent further mischief. Refraining from work was essential, and a sojourn in the country might be sufficient for the simpler forms without further treatment. The patient should arise late and go to bed early, in order to spare the nervous system from strain, and to limit the loss of urea the avoidance of movements and fatigue should be enjoined. The bowels should be kept free, and a tepid sea water bath or shower, followed by a good towelling, had been recommended by Ralfe. While care should be taken that the patient should not be exposed to too low a temperature, it was important that he should not become relaxed by too hot rooms or too heavy clothing. While, on the one hand, it seemed advisable to reduce the amount of nitrogen in foods, on the other hand this had not proved as serviceable as placing him upon a general diet. The main point in the dietetic treatment was not so much to control the nitrogenous element as to regulate all quantities of food so that the tissues should not be oversupplied, and the patient still be sufficiently nourished. This plan controlled the general as well as the urinary symptoms, though it fell somewhat short in the way of repairing loss of tissue; but if the patient recovered sufficiently, one was warranted in increasing the amounts of nitrogen, as well as of fats and carbohydrates—which meant more food. There was some difference of opinion as to the value of different drugs, although most authorities agreed that valerian answered the best purpose. Bouchard employed it with good results in the form of the extract, in gradually increasing doses; beginning with 8 grams during the day and increasing the amount to 20 or 30 grams in the 24 hours. Others recommended the use of arsenic, potassium bromide, belladonna and hyoscyamus. It was probable, however, that the best drugs were valerian, opium, and arsenic. The prognosis in the different forms mentioned varied according to the degree, the length of time the condition had lasted, and the presence of complications. When properly treated, all cases of the simple forms were cured, while most of the grave form were relieved of their symptoms, so that life was extended for a number of years. In the presence of complications, however, but little could be expected. This meant an extreme extent of breaking down of tissues and usually marked the threshold of the end.

Dr. Edward E. Cornwall said he would like to call attention to one point of extreme importance which he had not seen mentioned in the literature of diabetes, namely, that the diet should be so arranged as to make as easy as possible the processes involved in protein metabolism. The accepted dietetic treatments for the affection looked only to the restriction and selection of carbohydrates. They failed to take into consideration the nitrogenous metabolism, and, still worse, they imposed unnecessary burdens upon it, both by giving protein in excess and also by giving it chiefly in a form the metabolism of which was comparatively difficult, namely, animal tissues. Protein in that form put upon the liver, already incapable of performing its carbohydrate-metabolic duties, the work of breaking up purin bodies directly introduced with it and products of its putrefaction by the saprophytic bacteria in the intestines. In diabetes we would naturally expect the instability of the liver as regards its glycogenic function to be increased by such treatment, and it might be that this was partly responsible for the extreme limitation of carbohydrates which had so often been found necessary in order to clear the urine of sugar. The reasonableness of the argument now presented received emphasis from the fact that a large proportion of cases of diabetes were found in families in which gout, chronic arthritis, chronic nephritis, cardiovascular disease, and apoplexy were prevalent. It was, indeed, in treating persistent glycosuria in such patients, whose nitrogenous metabolism was obviously deficient, that his attention had been drawn to the therapeutic value of an "easy" nitrogenous diet in diabetes. By this was meant a diet which, though limited in quantity to the real wants of the body, contained the various food elements in their normal proportion, but in which the protein was furnished by articles which were purin free and comparatively insusceptible to putrefaction in the intestine. Such a diet was one consisting almost exclusively of milk and its products, cereals, fruits, and vegetables.

Dr. J. Wallace Beveridge said that one important fact had not been referred to, and yet it seemed to him that it presented one of the principal obstacles in the treatment, as well as one of the fundamental causes, of diabetes. In the observation of many cases of the affection he had found, from examination of the stomach contents, that in over 80 per cent. hyperacidity was constantly present. Radiographic examination had shown also that in over 75 per cent. of the cases there was present gastric dilatation with mechanical defects in the intestine. Baylis and Starling had demonstrated that a hormone, secretin, was manufactured in the pylorus and duodenum, as the result of acid stimulation. In normal digestion there was a sufficient amount of secretin produced to activate the normal internal secretions of the pancreas; but when we had an increased acidity of the stomach contents, an over-production of secretin necessarily ensued, and this excited the pancreas to an increased production of the internal secretions which in time, if permitted to continue, would cause a degenerative change in the pancreas and interfere not only with the breaking down of the carbohydrate group, but also cause inability to attack the protein molecule. Any changes in the pylorus or duodenum, such as ulcers or stenosis, interfering with the normal production of secretion might likewise be causative factors. The intestine played an important part in the digestion of the diabetic, and intestinal putrefaction should always be carefully guarded against.

Dr. Charles Herrman said that, according to his observation, diabetes was comparatively rare in children, and especially in infancy. It was only in small infants that there was any difficulty in getting a specimen of urine for examination. It seemed probable that syphilis was a more important factor in the etiology of diabetes than had generally been supposed. It was no doubt often latent, but

now that we had the Wassermann test to guide us, the detection of its presence presented less difficulty. Dr. Fischer had spoken of the association of diabetes with pertussis. It was a fact, however, that sometimes in pertussis the urine reacted to Fehling's test without true diabetes being present. It was also necessary to differentiate alimentary glycosuria from true diabetes, for while the one was of little significance, and easily cured, the other was extremely serious; the prognosis in this disease being worse in children than in adults.

Dr. Robert T. Morris said that Dr. Beveridge was correct in approaching the surgeon's point of view in relation to diabetes. Every one of these patients should be sent to a gastroenterologist in order to obtain a report upon the question of intestinal putrefaction. Toxins which were by-products of intestinal bacteria excited the secretion of morbid secretin; hormones, which dictated function to the pancreas, gave wrong messages. In addition to this, in cases of intestinal putrefaction the pancreas was frequently in a state of chronic congestion. Indeed, interstitial pancreatitis often occurred, and was unobserved by the clinician. In certain instances the islands of Langerhans were compressed, and they ceased to functionate properly. Diabetes mellitus was never a diagnostic entity, but always a symptom; and there were several causes for this symptom. We might have irritation of the floor of the fourth ventricle from toxic, mechanical or reflex causes, and in these cases it was a symptom quite as well as when pancreatitis squeezed the islands of Langerhans. If we did not first obtain a report from the gastroenterologist in all our cases of diabetes we were not going at the subject intelligently. Surgeons seemed to know more about the subject practically than the internists did. They saw many cases of diabetes fade away after removal of gallstones, separation of adhesions in the abdominal attic, correction of eyestrain, and the employment of proper methods for securing control of intestinal bacteria.

## Books Received.

*The* Medical Record *is pleased to receive all new publications which may be sent to it, and an acknowledgment will promptly be made of their receipt under this heading; but this is with the distinct understanding that it is under no obligation to notice or review any publication received by it which in the judgment of its editor will not be of interest to its readers.*

Spezielle Pathologie und Therapie Innerer Krankheiten. Herausgegeben von Friedrich Kraus and Theodor Brugsch in Berlin. Parts 1-4; paper; price per part 2 Mks.; illustrated; 238 pages. Urban and Schwarzenberg, Berlin and Wien.

## Miscellany.

**Medicine in the Italian Parliament.**—In the recent general elections held in Italy a remarkable number of physicians and surgeons, in consultant or in general practice, entered the field. Significant is the fact that it is precisely in those regions of the kingdom where the sick-rate and mortality are highest, and where physical degeneracy is most pronounced, that the medical candidatures in question were most numerous and most actively promoted. Southern Italy, notably the Neapolitan provinces and Calabria, are the regions indicated, no fewer than five medical candidates courting as many of their constituencies. Some of these gentlemen hold university chairs, besides being in consultant practice, and the question arises: How can they possibly find time to do justice to their pupils or their patients, on the one hand, and to their constitutents, on the other? The answer is that the Chamber of Deputies in Rome does not commence business till late in the afternoon, seldom before 3 P.M., and its business is invariably over between 6 and 7. As a matter of fact, there have been many physicians and surgeons in the Italian Chamber who have combined the two rôles, of practitioner and parliamentarian. Lanza, a Piedmontese consultant, honorably refused all official salary as Prime Minister on the ground that his professional honoraria sufficed for all his wants, while he found time not only to earn the said honoraria, but to lead up to the events which brought his illustrious client King Victor Emanuel in 1870 to Rome. Guido Baccelli is another of the consultants who hold a university chair and a seat in Parliament with conspicuous efficiency in both capacities. The eminent patriot and sanitary reformer, Agostino Bertani, surgeon-general in Garibaldi's revolutionary force, is yet another exemplar of the compatibility of the medical with the political career; while as to the senators who have been promoted from the Lower to the Upper House while keeping in touch as teachers and practitioners with medical science and practice their name is legion. Italy has everything to gain by the presence in her legislature of public-spirited consultants and practitioners, who, with no ambition for office, are yet prepared to give their thought and experience to the body politic, claiming as that body does, a serious and a systematic rehabilitation, in the sanitary sense, to which no Italian with any proper sense of citizenship can now remain indifferent.—*Lancet*, October 4, 1913.

**The Choice of an Automobile.**—A writer in the *Lancet*, commenting upon the recent motor car exhibition in London, states that the doctor in search of a car will feel confused unless he relies rigidly upon one factor in his choice—namely, the price which he will give. Generally speaking, there are two classes of physicians who need motors. There is the prosperous practitioner to whom price is of little importance. The other class comprises the general and the country practitioners, and the question of expense with the major part of them has to be considered. This class can probably be again divided into two, those who merely want a two-seater for their professional work and those who desire a car which they can also use for their families. If it is a matter of expense, it should be borne in mind that the light two-seater is much cheaper, not only to buy, but also to run and maintain.

### THE OCCUPATIONS OF AFEBRILE TUBERCULOUS PATIENTS.*

BY S. ADOLPHUS KNOPF, M.D.,

NEW YORK.

PROFESSOR OF MEDICINE, DEPARTMENT OF PHTHISIOTHERAPY, AT THE NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL.

IN discussing the occupations of afebrile tuberculous adults[1] before an association of sanatorium physicians, presumably I am expected to speak mainly on that class of patients who are under constant medical supervision, and not those discharged from a sanatorium as improved or arrested cases, who are, of course, afebrile, and constitute what is sometimes termed the economic cure; in other words, I shall not consider the patients who, though not completely cured, are discharged from the sanatorium sufficiently improved to resume their former or some other occupation whereby their earning capacity is restored.

The problem of what the patient discharged from a sanatorium should do or what to do with him has received careful consideration in a recent contribution by one of our own members, Dr. David R. Lyman of the Wallingford Sanatorium.[2] I think Dr. Lyman has clearly shown that it is wiser for the discharged tuberculous sanatorium patient to resume his former occupation under better hygienic conditions than to attempt to do work even in the open air, for which he has neither the training nor the necessary physical endurance.

Another interesting paper on the same subject is Dr. John H. Huddleston's recent publication under the title, "Is the Economic Problem of the Sanatorium Graduate Being Solved?"[3]

For lack of time I shall be compelled to omit a detailed consideration of what to do with the afebrile patients outside of institutions who are under the care of the private physician. All that can be said here is that the underlying medical principles which guide us in the management of the sanatorium patients must be the same in private practice. But when dealing with the latter class, we must remember that each case has its own non-medical problems, sometimes easy and sometimes exceedingly difficult to solve because of family, social or economic considerations.

To return, then, to the patients still under our supervision in the institution, we must first divide them into two great classes, the male and the female patients. The next distinction to make is whether the patient himself pays for his maintenance or whether he is an inmate of an institution maintained by the State, county, city, or private philanthropy. Of course, aside of these sociological considerations there are underlying medical principles which must guide us in the selection of occupations suitable for the various classes of patients enumerated. There are afebrile tuberculous patients who, although they have no rise of temperature at any time during the day or night, should do very little, if any, manual labor. I refer first to that large number of tuberculous individuals who are constantly dyspneic or who become so after the slightest physical exertion. Then come the cardiac cases with their various murmurs showing an evident lesion, or cases which merely give the manifestation of tachycardia. It goes without saying that cases inclined to frequent hemoptysis though afebrile should never perform any considerable manual labor. The same might be said of the patients who ordinarily cough little and have little expectoration, but whose cough becomes distressing and whose expectoration increases the moment they begin to do manual labor.

I also believe that the afebrile individual with a renal lesion should work but little. Then, there comes that group of patients whom you all have met with who have apparently a tuberculous lesion with very little activity, who are most of the time afebrile, but who simply go to pieces if they are put to work or perform any manual labor. Whether this condition can be ascribed to a peculiar degeneracy of the muscular system or to some other cause, I do not feel to be able to explain. This much is sure, we must individualize as far as possible in all cases, even in the sanatoria for the poor, where it is, of course, more difficult than in private practice.

I fully realize that in a State or municipal sanatorium, or one maintained by private philanthropy, where patients pay nothing or but little, by reason of the character of the inmates of such an institution, the physician in charge has to make another division of the patients able to do something, namely, those willing and those not willing to work. I know of no way to solve the difficult problem here involved except to divide the patients in some obvious way so as to make the lazy and indifferent ones ashamed of themselves, if such is possible. I would place them in a separate pavillion, and although I would give them the same food and medical care in case of need, it would seem to me perfectly justifiable to let the lazy class know that they do not awaken nearly as much interest and that the physician's attitude toward them could not be quite the same as toward the patients who are willing to cooperate for their own good and for the benefit of the institution by work and service.

In an institution like the one I am privileged to be connected with, located on an island from which escape is difficult, it is somewhat easier to induce

*Read before the American Sanatorium Association at the Ninth Midwinter Meeting at the Municipal Sanatorium, Otisville, N. Y., Dec. 6, 1913.

the unwilling worker to come to terms. One of my assistants, Dr. R. W. Grover, with the consent of the superintendent, Dr. Robert J. Wilson, instituted the practice of not allowing the patients unwilling to work to visit their friends in town. He who does not work will not receive a pass to cross the river on the department's steamers, and there are no other steamers plying between North Brother Island and the city.

As a rule, the afebrile patients who work under the supervision of the physician do well and even better than the afebrile patients who can work but do not wish to do so. To make known to the lazy class the beneficial results which are obtained for the workers of the sanatorium may be an incentive to at least some of them to change their attitude toward what is really a benevolent measure. It is a psychological fact which most sanatorium physicians have discovered that it is good policy when dealing with a large number of patients whom it is desirable to induce to work, not to make them feel that one is trying to get work out of them, but rather to show them the therapeutic value of the work for themselves. In some institutions, such as White Haven and Otisville, the patient is told on admission that when in the opinion of the physician in charge he is able to do some work, his refusal to do so will be followed by immediate dismissal.

Now, as to the character of the work the patients should do, let me state right at the beginning that I am not a partisan of the idea that every tuberculous patient, when on the road to recovery or when his disease is arrested, should do farmer's or gardener's work. The tailor, the weaver, the shoemaker, the dressmaker, or the woman or girl who has been occupied in the tenements with making artificial flowers for 50 cents a day, the bookkeeper, office or store clerk, the typewriter girl, stenographer, or shop girl, the waiter, or any other man or woman who was born and has lived in the city for years and pursued indoor occupations will as a rule make a poor farm hand. Some of these patients may be able to work a few hours on the farm, but they will rarely be satisfied, happy, or even contented, and I question whether their physique will ever be able, even when they have completely recovered, to stand the strain of a farmer's life.

What, then, is the ideal occupation for the afebrile tuberculous patient? I believe that, whenever it is possible, we must consider first the psychological, or in plainer words, the mental attitude of the patient. Whenever we can let us occupy him with something that will make him happy or at least contented, and the work must always be for a purpose. To have a patient carry a load from one end of the road to the other, or build a brick wall and tear it down again, merely for the sake of exercise, I believe is an absurd practice. If it could be done, I would even favor paying the patient, particularly if he is poor, for useful work accomplished by him; this does not lessen the value of occupation therapy, but enhances it.

Furthermore, when we consider that many patients need the money they may thus earn to support, or help to support, their families, we will perceive that besides the beneficial psychical influence, the peace of mind which is thus obtained for the patient invariably acts favorably on his physical condition.

To find an occupation for the tuberculous patient who has never had any fever is easier than for the one who has been rendered afebrile by prolonged rest in the open air. The latter is much more in danger of relapsing into his febrile condition than the former is to acquire a high temperature.

Let us consider for a moment the latter class—those who have been febrile and have been rendered afebrile. These individuals we can occupy in the open air, or indoors while there is plenty of fresh air, with an occupation that does not require much physical exertion. What we must see to is that the occupation does not demand a constant stooping attitude. The patients whom we wish to occupy by manual labor should, in order to avoid a recurrence to higher temperature, be prepared gradually for these tasks. All manual labor requiring physical exertion requires ipso facto increased respiratory function, and I do not know of any better way to prepare the patient for regular physical work than by a course of graded breathing exercises. The exercises I like best, which consist of a series of eight movements, bringing all the muscles of the body into play, I have described in my Hodgkins prize essay to be published in the early part of the new year, and reproduced recently by permission of the Smithsonian Institution's authorities in the MEDICAL RECORD of November 15.' When these exercises have been taken, say once or twice every hour for a few days, and the general condition has improved and no perceptible temperature rise is noted, I think the patient is ready for graded manual labor.

What shall the character of the manual labor be for those who have never been febrile and those formerly febrile who on trial of light work have stood the test so that they can be classified with those able to be occupied regularly?

In the sanatorium to which are attached a farm, a garden, woodland, or large grounds, workshops for tailors, bakers, shoemakers, carpenters, etc., the occupations in which a number of the patients can take part according to their former training, their physique and inclination are so multiple that I hardly need to enumerate them. Where there are woods and roads to be made, woodchopping, hut-building, and road-making offer additional opportunities. Some of the farming and gardening work can also be done by female patients. In inclement weather, sewing and embroidery or raffia work are interesting and healthful occupations for female patients, providing they do not acquire the habit of stooping and providing also that they interrupt their sedentary work by doing some deep breathing in the erect position every hour or so. I insist upon this practice in my hospital work.

In my service at the Riverside Hospital Miss Julia M. Off, formerly connected with the public schools of New York City, teaches the female patients the raffia and reed work, and as a rule they take to this occupation most enthusiastically, hardly ever tiring of it. Miss Off gives her services gratuitously, and I would like to embrace this opportunity to express our grateful appreciation of her kindness in this direction, also for her entertaining the patients occasionally with a piano selection. The Health Department very generously pays for the raffia and reed material. Very often the patients are able to dispose of their

products by sale, thus earning a little money, which increases their incentive to work. Rather amusing is the fact that because we have not sufficient occupations for the men at North Brother Island, not a few of them have taken up raffia and reed work and some have quite excelled their sisters in workmanship. I have wondered if the caning of chairs under careful supervision would not be a very suitable and in some instances very profitable occupation for the afebrile male patients.

The more the occupation of the patient in the sanatorium is like the kind of work he had done prior to entering the institution the more productive will the labor be and probably also the more contented the patient. I am reminded here of the brilliant idea which Lee K. Frankel, Ph.D., one of the vice-presidents of the Metropolitan Life Insurance Company, intends to put into practice in the sanatorium recently opened by that company at Mount McGregor for the cure of its tuberculous employees. In the work pavilion of the company, which is intended to be ideally constructed as far as sanitation, light, and ventilation are concerned, Dr. Frankel will give the afebrile patients employment very similar to that which they have been used to do in the home or branch office. The amount of work expected from the patients will, however, be prescribed by the house physician after careful examination and watching.

Of course, every patient in a public sanatorium who is able to wait on himself should do so, and making his bed, keeping the room or ward tidy, cleaning the floor and furniture with a moist mop or rag, and washing windows is not injurious to any tuberculous patient able to do the work. That class of patients who cough little and have learned to control their cough can, without any fear, be employed in the dining room and kitchen of the public sanatorium.

And now I come to a subject which perhaps may seem somewhat novel in relation to our discussion of today. I stated above that I like to prepare the afebrile patients for the more strenuous physical occupations by a series of breathing exercises, but I did not then mention that in my private practice I resort to an additional means of improving the muscular, respiratory, and cardiac conditions of my patients prior to allowing them to assume occupations demanding more or less physical exertions, walking or manual labor. This means of preparation is a carefully graded general massage.

The value of this therapeutic agent as a general stimulant and as of beneficial influence to the muscular, circulatory, and nervous systems is too well known to need more than a mention here; but that massage seems to be particularly beneficial in pulmonary tuberculosis because of its effect on the blood cells, I wish to emphasize, and quote as an authority Charles G. Taylor in Forchheimer's "Therapeusis of Internal Diseases," which recently appeared:

"The effect of massage upon the composition of the blood is a very definite one. The number of red blood corpuscles in the circulation will be found to undergo a substantial increase within half an hour after a general treatment, and to persist for an hour or more. The oxygen-carrying capacity of the blood is thereby increased, as is the elimination of carbon dioxid gas. Upon first thought, one would naturally conclude that this increase in the number of cells in the periphery is due to the stimulating effect of massage upon the circulation, and that the additional cells come from the inner recesses of the body, particularly the spleen, liver, and long bones, where we know they are constantly stored in large quantities. This conclusion is, of course, a logical and correct one, but there is also a definite influence produced upon the blood-making processes, as is clearly demonstrated by the permanent results obtained in certain anemic states when massage is given regularly. The percentage of hemoglobin in the red cells is also increased. This is notably the case in the treatment of chlorosis, where the deficiency in the coloring matter is the predominating feature of the pathological picture. Systematic massage, together with proper hydrotherapeutic methods, has proven of the greatest value in the treatment of this disease, and some authorities employ it to the exclusion of all iron preparations. In any depraved condition of the blood, general body massage given regularly every day will exert a markedly beneficial effect upon both the hemoglobin and the cell content.

"The leucocytes of the blood are also increased by massage, and to a more marked degree proportionately than the red cells. The importance of this fact is at once obvious. Since we have to depend to a great extent upon the phagocytic properties of the white cells to keep the body free from the attacks of the constantly invading organisms, and to remove the debris of exudates, etc., any agent that will favorably influence their production must be of real value."

The question has often arisen in my mind whether we cannot employ a number of afebrile fairly muscular patients to help us to apply this valuable therapeutic means to other afebrile patients less muscular and in less good condition?

It seems to me that this question can be answered in the affirmative, and I wonder if it would not be worth while for the gentlemen in charge of the larger public sanatoria to try the experiment. There is to my mind no need of great physical exertion on part of the masseur or masseuse if the massage is properly taught to them. The application of massage does not demand either great force or great skill. A relatively soft hand, a little good common sense, and a willingness to do it is all that is required. A few lessons suffice to teach simple massage which, as you all know, consists of four or five movements, that is to say friction, kneeding, tapping, and the vibration particularly indicated for the abdomen. The friction when done very gently is sometimes called stroking. Occasionally the pinching of the skin may also be indicated in individual cases of unusually sluggish circulation. All movements, friction, kneeding, tapping, are done in the direction of the venous circulation. The massage can be applied on the ordinary bed, and the masseur or masseuse can even remain seated during the greater part of the operation. The massage need not be longer than about half an hour for each patient. If there is constipation, the massuer should apply first friction in the direction of the movement of the hands on the watch dial around the umbilicus, gradually making a larger circle until he reaches the beginning of the ascending colon; he then moves upward to the transverse portion and follows the direction of this part of the large intestines to make a downward stroke in the direction

of the descending colon. An additional vibratory movement with fairly good pressure will usually prove to be a valuable means of overcoming a chronic constipation.

I have already stated that I believe in massage for the afebrile patient, but I hardly need to tell an audience of phthisiotherapeutists that massage of any kind is contraindicated in chronically febrile or hemoptic patients.

That I may not be misunderstood, I am willing to say that not everyone can become a masseur or a masseuse, but I believe many afebrile patients can do this work, help their fellow sufferers, and thus be usefully occupied. I for one would encourage a slight remuneration for such services. A patient should never be forced by the rules and regulations of the institution to do this kind of work.

In the above quotation from Forchheimer's "Therapeusis" you will have noticed the statement that systematic massage together with proper hydrotherapeutic methods has proved of great value in chlorosis. I do not think I need to emphasize how many times in pulmonary tuberculosis we find this type of anemia characterized by a marked reduction in hemoglobin out of proportion to the diminution in number of red blood cells.

Can we not also employ some of our afebrile patients in the application of hydrotherapeutic measures which, I am sure, many will admit are neglected at least in some of our public sanatoria because of lack of nurses or lack of hydrotherapeutic apparatus? I have taught and practised for years a method of hydrotherapeutic application which is so simple and safe and connected with so little expense that by training a few afebrile patients to do this work any number of sanatorium inmates would be benefited by the valuable therapeutic method which I will briefly describe:

The room should be comfortably warm, the windows closed in cold weather. An English bathtub containing about five inches of warm water is placed near the bed. Next to the tub a wash-basin filled with cold water is put on a table or stand. When beginning with these hydrotherapeutic applications in winter, the cold water should be tempered so as to accustom the patient gradually to the shock. If the douche is to be given during the day time, the patient goes to bed for twenty or thirty minutes. When thoroughly warm, he rises and steps nude into the warm water. The attendant then soaks the sponge in the cold water, which he squeezes out once over the back of the neck, once in front of the sternun, once over the left, and once over the right shoulder of the patient. The cold water will thus have reached every portion of the body except the head. The patient is dried rapidly, though not necessarily thoroughly, and then returns quickly to the bed, which should have been covered when he left it to retain the warmth. By this method reaction is assured.

The afebrile patient could also easily be trained to apply a wetpack or do partial sponging to reduce the temperature of his less fortunate febrile comrades. There are many other duties which the intelligent afebrile patient can perform as an attendant or an assistant to the nurse, such as taking temperature, applying dry-cups, giving the medicine according to prescription, etc., etc.

Before concluding the portion of my paper dealing with physical occupation and labor, may I state here what I tell every one of my private patients as the best guide to avoid excesses and the often disastrous results of overdoing? Never work, walk, or perform any physical exercise when you are tired and stop exercising when you feel that you are getting tired.

I realize of course that the sanatorium man when he has to deal with what I designated above as the lazy class will have difficulty in applying the rule, for this class of patients will probably always say that they are tired, and if this excuse would avail no work whatsoever could be gotten out of them. Leaving the lazy class aside, it would seem best that every afebrile patient should be put to work gradually, say beginning with two hours per day and slowly working up to six, interspacing the hours of work with hours of rest.

The great therapeutic value of the rest hour before and after each meal, or what is sometimes designated as the silent hour, is now, I believe, fully appreciated by all sanatorium men and phthisiotherapeutists in general. To my mind, we cannot attach too much importance to this helpful hour in the life of the tuberculous. To get complete relaxation and rest during the silent hour it is of course essential that the patient reposes either on his bed or on his comfortable reclining chair and no noise of any kind should be permitted to disturb his siesta. In institutions where the patients have to wait on tables and wash dishes afterwards, arrangements should be made by shifts to give the workers as frequently as feasible the opportunity for observing the silent hour.

I have not been asked to speak on what is known as typical occupation therapy in pulmonary tuberculosis, producing autoinoculation. Even had I been asked to do so, I have had too little experience with it to speak authoritatively on the subject. That it is indicated in some cases I do not question. Marcus Paterson to whom I believe belongs the credit of having first inaugurated this therapy, has given a complete survey of the method in his book.[4] In this country, our distinguished President, Dr. Bowditch, Dr. King of Loomis, and one of his former assistants, Dr. George W. Beach, now of the Minnesota State Sanatorium, and I believe a number of others in various American sanatoria, are trying Paterson's method. Those who are interested in this unique therapy, I advise to study Paterson's book and communicate with the gentlemen just named who are members of this association, concerning methods and the results obtained.

At the Eighth Annual Meeting of the National Association for the Study and Prevention of Tuberculosis, Myer Solis Cohen and Albert Strickler reported on the effect of graded work upon the leucocytes in pulmonary tuberculosis, which paper constitutes also an interesting contribution to the literature on the subject.[5]

Whether we should resort to occupation therapy *per se* with a view to producing higher temperature and subsequent auto-inoculation for a curative purpose, or whether it is wiser to prevent the recurrence of fever and merely employ the patients usefully and as a means of strengthening their enfeebled organism and making them become again breadwinners and useful members of society, is a question which needs further study. I am willing, however, to admit that for the time being I am inclined to favor the latter practice, for what we do know and what we see here right before our

own eyes in Otisville is the inestimable value of useful occupation of the afebrile patient under careful medical supervision. That this class of patients on their discharge from the sanatorium are physically, mentally, and morally better fitted to resume their former occupations there seems to be no doubt. It is probably this conviction, arrived at as a result of his studies of the economic problem of the sanatorium graduate, that made Dr. Huddleston, referred to above, plead ardently for the formation of farm and industrial colonies as annexes to existing sanatoria.

Our distinguished guest, Prof. Hermann M. Biggs, M. D., the General Medical Officer of the City of New York, to whom we are indebted for the inauguration of so many valuable methods and schemes to successfully combat tuberculosis as a disease of the masses, is as you know responsible for the recent passage of a bill in the New York legislature to favor the establishment of industrial colonies in connection with the tuberculosis sanatoria of the Empire State. This bill is such a model of conciseness that it may well serve other states and municipalities as an example for similar action, and I believe it well worth the while to reproduce it here:

135-a. *Workshops in Connection With Tuberculosis Hospitals.*—Any municipal corporation maintaining a hospital or a sanatorium for the treatment of tuberculosis may establish and maintain workshops in connection therewith for the production of articles of supplies required by such hospital or sanatorium, or by any other institution or department of such municipality. Except in a supervisory capacity no person shall be employed in such workshop or workshops unless he is or shall have been a patient suffering from tuberculosis in such hospital or sanatorium. The appropriate municipal authorities may appropriate or provide funds for the establishment and maintenance of the said work shops in the same manner as for the establishment and maintenance of such hospitals or sanatoria. Notwithstanding the provisions of the prison law in relation to the sale of articles manufactured in the State prisons, the products of such workshop may be used in such hospital or sanatorium or by any other institution or department of such municipality. Such workshops shall be under the direction and control of the hospital or sanatorium to which they may be attached.

2. This act shall take effect immediately.

I would not consider my paper complete were I not also to say a word on the mental occupation of the tuberculosis patient. I believe it is generally understood that most of the highly febrile patients should even refrain from any mental strain; on the other hand, I believe that reading pleasing and consoling literature to a febrile patient is not harmful and may be beneficial. Here, again, is a way in which some afebrile patients can be usefully occupied in helping their less fortunate fellow sufferers, ill with fever. Even the strains of pleasing music are, I believe, not out of place in or near the sickroom.

For the afebrile patients up and about, who are occupied for some hours with physical labor, there should be furnished some mental food along educational lines. What a wide range of subjects can be covered, particularly in the sanatorium for the people—I mean the masses who have not had the opportunity of a good education—is difficult even to describe. For every letter in the alphabet there seems to be a subject of interest to the masses—astronomy, biology, chemistry, cooking lessons for the female patients, popular dentistry, economic housekeeping, eugenics for the tuberculous, electricity, entomology, and other natural sciences down to the wonders of the *x*-rays. All these will appeal to a lay audience when rightly presented. Of course, the talks on hygiene, temperance, tuberculosis, and allied preventable diseases, the value of personal and social service as a means to increase the happiness of others and our own should not be neglected, but every one of these lectures must have a ring of optimism in it, and besides entertaining, it must tend to uplift, inspire, and encourage, but never depress.

Our main agents in the cure of tuberculosis are as yet, air, food, light, and the constant watching and guiding of our patients. Our personality, our cheerful attitude, our words of hope and encouragement or consolation, will also count for a good deal. Thus, besides praying for an abundance of physical sunshine for our poor patients, let us resolve always to carry with us as one of the indispensable factors in modern phthisiotherapeutics, an abundance of mental sunshine. The results with our patients will be all the greater and our own lives all the happier for it.

## HYGIENE OF THE FARMHOUSE AND FARM.

BY J. A. NYDEGGER, M.D.,

BALTIMORE, MD.

U. S. PUBLIC HEALTH SERVICE.

SANITARY laws in great numbers have been enacted and enforced for the betterment of the complex health conditions of our cities. Extensive public health educational campaigns have been carried on in all that pertains to health and hygiene; and in the onward movement which at the present time is being agitated more than in any former period, in behalf of better methods of living, physically, mentally, and morally, with the great advances made in hygiene, eugenics, and euthenics, the rural and urban districts, which now offer the most fruitful fields for the promotion of hygiene, in all the term implies, seem in a great measure to have been overlooked, and practically passed by, with but few exceptions, and, up to the present time, almost forgotten. This has been due in a measure to the engrossing attention paid to improving health conditions in the cities and larger towns, while the country areas have been sadly neglected. Other factors of importance in this connection are the remoteness of some of the sections from the more populous centers and environs, and partly through lack of knowledge and ignorance of the existing injurious environment, in so far that the rules for correct living and good health have been almost completely ignored.

In further explanation of the backwardness in the rural health movement, it might be said that the non-investigation into the true status of health con-

ditions in rural communities more thoroughly, has not been intentional on the part of the sanitary and health officials of any State, but partly follows as a result of the lack of interest and knowledge of the inhabitants themselves of the said areas.

If we but stop to consider for a moment, the facts are plainly brought home to us—and more especially to those of us who are somewhat familiar with rural life and rural conditions—that the main source, the fountain heads, so to speak, of a number of diseases have their origin chiefly in the country, and are there maintained by reason of the more favorable environment, that is, in being more unhygienic and more insanitary, for their propagation and spread. If we take the average farmhouse, of people in moderate circumstances, located some distance from a city, we are liable in the vast majority of instances, at least, to find that running water is not supplied in the building, that the all cleansing and health-giving bathtub is wanting, that the water closet is not placed in the house, but has a highly dangerous substitute in the way of a privy or outhouse, badly constructed, and frequently in still worse state of repair, unscreened and unprotected, located at some point in the yard, or elsewhere when no enclosure is thrown about the house. As we know, a privy or outhouse is designed primarily to prevent soil pollution, and hence to prevent the spread of disease through dissemination, but nearly always is an inferior substitute.

As a result of the neglect of attention to these simple but important, and now well-known precautions, flies, and other insects, after having access to the unprotected outhouse and excreta, readily gain access to the dwelling through the unscreened doors and windows, and convey the pathogenic organisms of disease on their legs and bodies to the food and drink of the occupants. It is now a well-established fact that typhoid fever, to which there is annually sacrificed in the United States alone the appalling number of from 35,000 to 40,000 lives, can be obviated to a very great extent by the observation of well-known and comparatively simple precautions. Typhoid fever is distinctly a disease of the country; that is, its prevalence is greater in the country than in the city; and it has been conclusively shown that the propagation of typhoid fever in the United States is from the country to the town; and based on a most moderate estimate, nearly one-half million of people are attacked annually with this disease in this country.

By inadequate, or more frequently by the absence of, screens on doors and windows, malarial infected mosquitos gain access to dwellings (I now refer more particularly to our Southern States), and infect the occupants with malaria, or *vice versa*, having fed on those suffering with the disease within, fly north after having sated their hunger, to subsequently bite and infect those who may be unprotected in the vicinity, whether within doors or without, thus resulting in much illness and suffering, loss of valuable time from work, so necessary as a means of livelihood, both for themselves and those dependent on them; a very grave condition of affairs indeed, as compared to the comparatively trivial outlay for providing the important means of protection. In such a farmhouse as I have described the source of the drinking water supply is usually a shallow well, or a spring, located frequently near the dwelling and also very often near the privy.

Colonel Waring, one of the most noted sanitary engineers this country ever had, has rightly said that a pure water supply is the most important factor in the reduction of death in a community, and the next most important after that is the proper disposal of sewage. With insanitary and unhygienic conditions existing about the farmhouse, in the manner as above stated, the result is that the soluble excrementitious matter from human beings and animals, sewage, waste water, and slops from the dwellings, whether deposited on the surface of the ground or in a privy, pit, or cesspool, assisted by the falling rains, eventually reach the ground water, and seeping through the shallow strata of earth, eventually finds its way into the well or spring, and pollutes it. In many instances, too, the ground water contains the specific pathogenic organisms of the water-borne diseases, such as typhoid fever, bacillary and amebic dysentery and diarrhea, and in addition to the pollution make the use of the water dangerous for domestic purposes and a risk to health; for in using such water the occupants of the house would be literally drinking their own excreta. Also in addition to the danger of conveyance of the pathogenic organisms to the system in the food and drink by flies and insects; where the privy is not properly closed, or is open at the back, animals, such as dogs and hogs, chickens and ducks have access to the excreta and further disseminate the pathogenic bacteria contained therein, by scattering the excreta about on the ground and further polluting the soil, and eventually the drinking water, as has just been described. It is by the above method chiefly that hookworm is disseminated in the South, by soil pollution from improper and unprotected and hence insanitary privies, and other equally as bad methods of disposal of human excreta, as practised in rural districts—the hookworm eggs being contained in the excrementitious matter.

These shallow wells, which are so extensively in use in the country districts and urban towns everywhere, are the poison of the farms and towns alike, and I cannot speak in terms too strongly in favor of their discontinuance. They easily and quickly become polluted by sewage and excrementitious matter from the nearby houses, and illness of a serious nature from the use of the water is frequently the result. We now know beyond longer doubt that the chief source of conveyance of typhoid fever is the use of impure water for drinking and other domestic purposes, while food and fingers play their part.

Having pointed out briefly some of the undesirable, insanitary and hence unhealthy conditions that exist in and about a farmhouse, what rules must be observed, say rather enforced, in the average country home, in order that the occupants may, as far as possible, be protected from disease, may enjoy more hygienic surroundings, and better health be promoted:

First, the location of the house is of great importance. If possible, it should be placed on high ground, such as an eminence. It should be properly oriented so as to receive the maximum amount of sunlight throughout the day. The foundation should be constructed in such a manner as to keep the ground moisture out of the building. Then the house should properly be provided with a modern water closet and bath, also supplied with an abundance of cold and hot water, complete water connections, and a water carriage system, and be provided with proper provisions for heating, ventilation, and lighting, both natural and artificial. The

sewage from the house, including all waste water and slops, should be disposed of in due manner, preferably by the septic tank or Waring system.

If running water can not be supplied to the house in a practical and economical manner, the next best and most accepted method of excreta disposal should be resorted to, and the privy or outhouse must be located on the ground at a safe distance from the rear of the building, and be properly constructed and screened to prevent the ingress of flies and insects, and be provided with pail or dry earth receptacles, which should be emptied at regular and stated intervals, and the contents disposed of under strict sanitary precautions, as by burning, or burying at a safe distance and away from any possible source of water supply. The water supply of such a farmhouse should be from a source of undoubted purity, a deep or artesian well, or, in case this is not practicable, the spring, if one, should be protected from inflow of surface water, and when from the latter source, the drinking water should as a rule be boiled before using, this precaution being especially carried out during the prevalence of an epidemic of typhoid fever or other water-borne disease in the vicinity. In case of the poor rural dwellers whose small houses or cabins are located in the distant valleys or in the fastnesses of the mountains, the risks to the health of the family, frequently ignorant and unlettered, are usually much greater, depending somewhat upon environmental and other conditions.

By reason of the often low pecuniary condition of the occupants (of such houses) the methods of promoting hygiene and safeguarding health in the farmhouses and homes will prove a most difficult problem in numerous instances to handle, and to successfully solve. The same sanitary rules and precautions, as heretofore stated, will apply equally as well to all, however, though they will perhaps meet with less success in many cases. The poor people of our mountainous countries as well as those of the lowlands, the former numbering some 2,500,000 to 3,000,000 souls, should not be forsaken and left to their fate, the former representing, as they do, the only pure American stock, but every effort should be made, as far as possible, to help them and provide for them the simple precautions and safeguards of health. In this class of farmhouses, too, the subject of lighting, both natural and artificial, plays an important part in the health role. To one unaccustomed to such sights, the fact of families living in houses without windows and shaded in gloom and darkness at midday is almost unbelievable at the present time, but one has to go no further away than the mountains of Kentucky, Tennessee, North Carolina, West Virginia and Virginia, and other States, to be convinced of the aforegoing statement. The methods of artificially lighting these homes of the poor are also frequently inadequate and unsatisfactory, leading to eyestrains, headaches, and other discomforts, and eventually impairing visual acuity. Poorly kept lamps, lanterns, and even tallow dips are the common methods of illuminating these homes.

The manner of cooking and serving the food plays a very important part in the health status of the poor rural dweller, as also often elsewhere. Badly cooked food deprives the person of much of the nourishment that would be contained in well-prepared food of the same quality. This results in lowered vitality and energy on the part of the consumers, and renders them more liable to contract disease. The substitution of the boiler and the pot for the "frying pan" in the preparation of food will prove of much benefit, and will rid many of the chronic sufferers of rural communities of the pangs of indigestion and kindred ailments. The excessive use of beverages, such as coffee and tea, to which many of the country dwellers and elsewhere, are addicted, has a detrimental effect on health, producing indigestion, insomnia, nervousness, and allied disturbances. The remedy for all of this is not so much good lamps, as well kept lamps, not so much good quality of food as the quality of food well cooked, and the use of the usual beverages in more moderation.

The sanitary privy as described by Stiles and others of all measures suggested to improve health conditions in rural and urban areas, when universally adopted and put into use, will, in my mind, prove the greatest boon, because of its efficiency, its simplicity and its low cost, thus placing it within reach of all. It is sincerely believed no other sanitary precaution or measure ever suggested will promote hygienic conditions and prevent the dissemination of disease-containing human excreta in rural or urban life more than the use of the privy above mentioned.

The farm, too, in the vast majority of instances is susceptible of many improvements in a hygienic way. Where lowlands, marshes, ponds, and bodies of stagnant water exist, which might harbor or furnish breeding places for disease disseminating mosquitos or other insects, ditching, draining, and filling in will greatly promote hygienic conditions. Damp, low ground has also an injurious effect on health in a general way, by lowering the vital resistance, and thus permitting the contraction of tuberculosis, diphtheria, rheumatism, tonsillitis, and perhaps diarrhea more easily; and dampness acting in conjunction with a decreased amount of sunlight makes the conditions still more favorable for the development of disease, and the harboring of insects which disseminate diseases. Hence the farmhouse should not be located in or near a thickly grown-up tract of woodland, but should stand out clear and free from such light-obstructing and insect-harboring sources, although a limited number of trees for shade and ornamental purposes, provided they do not overhang the house, are desirable.

All stables, barns, pigstys, hen houses and coops should be located at a distance sufficiently great from dwellings and source of water supply to prevent any possible contamination by flies, bugs, and other insects by direct contact with the houses, and also to prevent surface draining into the well or spring from such places. All outhouses and tenements of whatever nature occupied or used by help or employees should also be equipped and provided in the manner already stated. All cows furnishing milk for home consumption, or otherwise, should be maintained in good health, in modern sanitary stables. The milk should be taken from them in a cleanly and approved manner in clean receptacles and preserved in cool and clean containers, and at stated intervals the herd should be subjected to the tuberculosis test, to detect any case of incipient tuberculosis. The manure and refuse from all stables, animals, fowls, etc., should not be thrown out in the open and there left to serve as a breeding place for flies and other insects, but should be received in a dark fly-proof room and there remain until properly disposed of.

Many other subjects, some of a more or less es-

thetic nature, which have an important bearing on the promotion of hygiene of the farmhouse and farm, such as providing circulating libraries, moving pictures, music, societies, for diversion and amusement, and others, might well here be discussed, but time will not permit.

Having dwelt upon the insanitary and unhygienic conditions within farmhouses and on farms, naturally, the question is asked, what is the solution of this whole problem? The answer is, education in public health matters, and the adoption of a State-wide policy of improved health measures. The splendid health organizations in force in some States, cities, and larger towns, only need extension and increased scope of action to include rural districts in all of their beneficial operations, while others need to have health departments organized and put on a proper footing of efficiency.

Many of the public health problems of our country are difficult of solution, and will require the outlay of much time, talent, and money. The latter is not always forthcoming from the State Legislatures, but with it in hand the other two can be obtained. As has been said, what is most needed to improve and promote the hygiene of farmhouse and farm is the arousing of public interest in all matters pertaining to hygiene and health. This can be accomplished effectively in only one way, and that is by public education, by lecture campaigns, talks, traveling exhibits, by interested organizations and individuals; and it is to be hoped soon through the rural district nurse to advise, and under the supervision of State health and sanitary officers, to extend assistance and spread public information on these important matters, bearing so closely on the essentials of rural personal hygiene, which will penetrate the most remote settlements, away from city centers; and by this means, and by utilizing ministers, school teachers, churches, school houses, tents, stores, halls, or, possibly in instances, moving train exhibits, that all residents of such districts can be reached and interested and instructed, and brought to realize that life can be conserved and prolonged by observing certain and not difficult hygienic rules, thus insuring increase of health and happiness, and in the end greater prosperity in any rural community.

The greatest evil today in our rural States is undoubtedly the existing medieval sanitation. There are numerous sections in which sanitation in respect to soil pollution and care of milk is only one-tenth what it should be. The recent wonderful awakening on the part of the State Boards of Health and State Boards of Education in respect to these points in certain sections of our country can not be praised too highly. The initiative in solving these particular phases of rural needs is, therefore, taken, but time will be required for the development of public sentiment along these lines among these people, and for the passage and enforcement of State and local laws, that will decrease pollution of the soil and of the water, and milk supplies.

District nursing is another sad and crying need of our farm areas. The average country woman, white or black, has exceedingly rudimentary ideas on the subject of cleanliness, housekeeping, and care either of children or the sick. To meet the needs of this side of the problem the district nurse seems capable of playing a most valuable role. Highly advisable in this connection is the adoption by the States of a universal policy looking to the improvement of methods of care for the sick in rural and small urban communities. A survey of conditions in rural districts will show that in case of sickness in families, the patients will lack more or less of the care which their condition demands. The survey will show that a certain large percentage of those ill could not afford to pay for such care as is required. It will also show that hospital and institutional care will be found to be most noticeably lacking, and that of the large number who require hospital treatment, only a small percentage receive it, and still a smaller number of those who should have been admitted to other institutions were thus dealt with. Another crying need which is inadequately met in rural districts is that of housekeepers for families in which there is no wife or daughter to look after the running of the house, or in which she was the person incapacitated by illness.

While this particular mode of procedure is not in line directly with the promotion of public sanitation in rural areas, it has a most important bearing on this problem, and has for its object the bringing about the betterment of the treatment of the sick, and thereby indirectly promoting health in any community whatsoever.

## TUBERCULOSIS OF THE TESTICLE.

By A. L. GOODMAN, Ph.G., M.D.,
NEW YORK.
VISITING PHYSICIAN TO THE "A. JACOBI DEPARTMENT FOR CHILDREN" OF THE GERMAN HOSPITAL.

A. G., aged 2 years and 10 months, was admitted to the Children's Department of the German Hospital because of a swelling of the testicle. His mother stated that the swelling became apparent only a few months before, and had been growing steadily ever since. Upon admission, the testicle measured about 3 by 2 cm. There was no pain or tenderness on pressure. Palpation of the cord was normal; the inguinal rings were normal. There was nothing in the past history of the child that would have accounted for its present condition, in the way of injury, or other accident. The family history, as far as the mother knew, was negative. The general appearance of the child was good, and he looked well nourished and developed. No glandular enlargement could be felt in any part of the body. The lungs were perfectly normal; there were no heart murmurs; the pulse rate and rhythm were regular and of good quality. The abdomen was normal; no masses could be felt. The reflexes were normal. Von Pirquet reaction proved negative.

The child was operated upon a few days after admission to the hospital. One inch incision on the left side, parallel to Poupart's ligament; fascia divided, and the testicle expressed out of scrotum; gubernaculum cut away, the tunica vaginalis opened and removed from testicle; vessels of testicle ligated; epididymis ligated, and testicle cut away; skin sutures of light silk-worm gut. The wound healed by primary intention.

The pathological report is as follows: "Anatomical Diagnosis: Tuberculous epididymitis. Gross appearance:—Specimen consists of a testicle removed from a child of three years. It measures 3 by 2 by 1.5 cm. It has been cut in several directions. The outer surface is still covered by a portion of tunica, and attached to it is about 2.5 cm. of the vas deferens. On section, the normal architecture of the organ is almost completely obliterated. The parenchymal tissue is separated in small nodules and islands by wide, glistening, white bands of fibrous tissue. The distinction between the epididymis and the testicle proper is difficult to make out. The greater portion of the mass, however, appears to be composed of enlarged epididymis, the body of the testicle apparently being represented by a small nodule about 1 cm. in diameter. In some regions are found yellowish cheesy necrotic areas, resembling tubercles. The vas deferens is exceedingly small, but does not appear beaded. No distinct tumor can be made out.

"Microscopical examination. A section through enlarged epididymis shows the normal structure to be almost completely replaced by abundant typically

formed tuberculous granulation tissue. The tubules of the epididymis are represented by scattered ducts lined by columnar epithelium embedded in this granulation tissue. The tubercles are both discrete and conglomerate. In some regions, extensive areas of caseation are found, but these are comparatively slight. Langerhans' giant cells are very numerous and large. The vas deferens appears normal as does also the accompanying tissue of the spermatic cord. The small portion of glandular tissue in body of the testicle appearing in the section, also appears normal."

Under the heading of "Three Cases of Tuberculosis of the Testicle in Infants," reported by Vignard and Thévenot,[1] the authors state that: "Tuberculosis of the testicle is relatively rare in children. The frequency of the disease being four times less in children, as compared to adults. The admitted proportion of testicular tuberculosis is one case in two hundred cases of infantile tuberculosis. Many latent cases in general tuberculosis are apt to be overlooked unless the little patients are subjected to a routine examination. The reported cases show the predominance of this disease in very young children. Of these three patients one was 11 months old, another was 14 months old, and the third was 6 months of age. Cholmeley's patient was 6 months of age, Hochsinger's patient 13 months, and two cases of Swoboda concerned nursing infants. The four patients of Lannois were between 6 and 13 months of age. Among seventeen patients of Julien twelve were under 2 years of age; Dreschsfell emphasized that the tuberculosis may be noted at the time of birth. Vignard found no analogous cases in his review of the literature.

Testicular tuberculosis may appear either as a primary isolated manifestation or as a secondary complication in the course of a visceral tuberculosis. Primary tuberculosis is, at the same time, very restricted; unilateral, and not extending above the inguinal ring, it spares the better portion of the vas deferens, the seminal vesicles and the urinary organs. Hence, it is essentially curable. It does not especially involve the epididymis, as in adults, nor is it essentially testicular, but involves both the testicle and the epididymis, blending the organs into a pathological mass in which the primary infected organ can no longer be distinguished. Macroscopical examination shows that the mass, which is at first diffuse and indistinctly outlined, has a certain tendency to become encysted; the connective tissue which proliferates in the vicinity may even infiltrate the gland in its entire extent, and atrophy through testicular sclerosis is often the outcome of the infection. In other cases, the tuberculous nodule suppurates, as in adult cases, it is adherent to the skin, then a fistula opens at the exterior, at the level of the tail of the epididymis, as is the rule in tuberculous fistulæ. More rarely, other forms of tuberculosis are observed, such as tubercular granulations or nodules scattered in the thickness of the gland; granulations or nodules in the head or tail of the epididymis. The vas deferens is often involved, but although it becomes indurated, as in adults, it is attacked only in the lower segment which is still enclosed in the scrotum. The tunica vaginalis is often the seat of a more or less profuse exudation, in other cases, the two layers have become adherent through a plastic process, forming a shell, as it were, around the genital gland.

Secondary testicular tuberculosis is usually more extensive and no longer the manifestation of an infection through the blood. In certain patients the infection is propagated through the lymphatic group or by the vaginoperitoneal canal. An ascending infection through the vas deferens is rather doubtful; the lesions are sometimes bilateral in these cases and the seminal vesicles or the prostate are apt to be the seat of indurated nodules or even suppurative foci. Clinically, these changes begin with acute symptoms, or they may be chronic from the start. The chronic types are essentially indolent, and their existence is only revealed accidentally or by the appearance of abscess and fistula. According to all writers, the primary forms are relatively benign in character, whereas the remote results of the secondary group are extremely unfavorable and the invasion of the testicle is here interpreted as a sign of profound intoxication of the organism, indicative of a fatal outcome. The observations of Vignard and Thévenet do not confirm this general opinion, for their primary tuberculous cases ended in death, and the difference between the primary and the secondary forms of the disease does not seem to them as considerable as is generally assumed to be the case.

Case I.—Boy 12½ years old; lesion of left testicle of about six weeks' standing. Mother died of tuberculosis. A sister died in infancy of tuberculous meningitis. Patient himself was operated upon for right inguinal hernia at the age of 3 years. Coughed since early childhood. The testicle, at the time of his admission to the hospital was of nearly normal size; the epididymis was very large, hard, and somewhat irregular; the vas deferens was likewise indurated. General condition, satisfactory. Treatment consisted in epididymectomy and resection of the vas deferens to an extent of 10 cm. The patient was discharged about 7 weeks later with a small fistula.

Case II.—Boy 14 months of age was admitted for tuberculosis of the left testicle. Family history good. Trouble began one month ago with redness and swelling of left half of scrotum. Eight days ago a fistula opened from which escaped a serous yellowish pus. Local examination showed the existence of two swellings,—the upper, the size of an almond, corresponding to the testicle, which did not seem much changed, the lower one was more voluminous, and was formed by the epididymis surrounding the testicle. At its lower pole was the above mentioned fistulous tract. In its lower portion was found a tubular vas deferens which could be felt all along the inguinal tract. No other tuberculous lesion, visceral or elsewhere. The treatment consisted in partial castration, extirpation of the fistulous tract of the epididymis, and of the portion of the testicle adherent to the epididymis. The child was discharged from the hospital with a persistent painful induration at the level of the affected region. He died about six months after the onset of the disease.

Case III.—Boy 11 months of age was admitted, with symptoms of tuberculous epididymitis. Two months previously a swelling was noted in the left half of the scrotum. This improved at first under hot applications, but then remained stationary. At the time of admission, the right scrotum was nearly the size of a fist, and was covered with a red, inflamed looking skin. Palpation showed a hard mass in the upper portion which seemed to belong to the testicle. The epididymis could not be isolated. In the lower portion, a fluctuating mass was felt with incipient formation of a fistula. The vas deferens was easily recognized and was found to be changed especially in its lower portion. No signs of pulmonary tuberculosis; no temperature; general condition satisfactory. The patient was castrated, and the incision of the infected region showed that the epididymis had been destroyed by suppuration. Only a small portion of the testicle was left. On account of the existence of a suppurative focus, the wound was drained. The patient was taken from the hospital by his parents on account of grave meningeal symptoms. Locally there was a small persistent suppurating caseous focus. Death eight days after the operation, two months after the mother had noticed the testicular swelling.

Case IV.—Cholmeley[2] reports a case of tuberculous testicle in a child aged 6 months. A section of the testicle, after removal of the organ, showed numerous small caseating foci in the epididymis; the body of the testicle appeared to be perfect. In the course of

the month following operation, the child developed measles and broncho-pneumonia, and died. Post-mortem examination showed the presence of tubercle in some bronchial glands in the left pleura, in both lungs, especially in the left; in the mesenteric glands; and in the left kidney.

Broca[3] contributes three observations on tuberculosis of the testicle in children. In two of his patients the diagnosis was practically positive, and in the third case it was not only possible but probable. The first patient was a boy of 13 months, in whose case the affected organ could not be properly palpated on account of retention in the inguinal canal. The next patient was a boy of 10 years whose local condition was that of epididymis, with a large nodule, especially in the head of the organ. The last case concerned a boy of 15 years whose left testicle became painful and swollen after a bicycle ride. At the time of admission to the hospital, a fortnight later, the scrotum was reddened and edematous, deeply adherent, with a purulent collection at the upper and lower pole of the epididymis. After formation of a fistula, and cicatrization, the patient retained an indolent induration of the epididymis, with nodules, especially at the head and tail, having the characteristic features of chronic tuberculosis.

Hutinel[4] emphasizes the fact that tuberculosis of the testicle is found especially in very little children about 2 years of age. Among twenty observations of Julien, twelve were less than 2 years of age and six were under 1 year.

Giralvis and other writers have even noted a congenital tuberculosis of the testicle in newborn infants. The disease may strike any age, but it is not common in older children. Poissonnier[5] says that tuberculosis in children is a rare disease.

Among ninety-one cases of different authors, about one-half concern the first two years of life. Heredity plays the principal part in the etiology.

R. J. Howard[6] believes that if general hygiene and opsonic treatment do not rapidly improve a tuberculous testicle in a child, the organ should be removed. If both testes are attacked, or if one has already been removed, orchidectomy should only be done as a last resort. Howard studied nine cases of tuberculous epididymitis in children under 12 years of age, admitted to the London Hospital between the years 1896 and 1905. In contradistinction to tuberculosis in the adult epididymis, where the disease is usually secondary to diseases of the prostate and seminal vesicles—the inflammation spreading along from the vas to the testis—in children, the epididymitis is usually primary, the bacillus being brought by the blood stream of the lymphatics. In the nine cases only one is stated to have been associated with the disease of the vesicula, and this receptacle was found to be caseous at the autopsy. In these nine cases, the diseases were on the left side in four; on the right side in two; and in the other three, both testicles were diseased, with the left side always more affected than the right. The more frequent occurrence on the left side was attributed by Howard to some difference in the blood supply and venous return. In only two of the cases was there any marked history of tuberculosis in the family. The average age of the nine cases was three years and two months—the oldest being ten years and the youngest six and a half weeks.

Hochsinger[7] reports a case of tuberculosis of the testicle in a child 1 year of age upon whom castration was performed. The lower third of the affected organ was found to be transformed into a tuberculous cavity; the swelling of the testicle was first noticed when the patient was 4 months of age.

Swoboda[8] observed two cases of tuberculosis of the testicle in infants. The first patient was less than three weeks of age; the second case is noteworthy in so far that the parents refused operation, and a suppuration of the caseous testicle followed, with apparent recovery.

Venot[9] presented before the Bordeaux Pediatric Society a case of tuberculosis of both testicles of long standing, and which had apparently been cured.

L. Rocher[10] contributes a number of observations on cases of primary tuberculosis of the epididymis in boys between 1 and 9 years of age. In a general way he states that the primary disease is very rare in children, because the organs are undeveloped and functionally latent, with a low vascularization and a slight tendency toward congestion, so that they are not well adapted to infection by way of the blood current.

Moizard and Bacaloglu[11] contribute a review of genital tuberculosis in the infant, and agree in the main points with the authors already quoted.

In closing it is interesting to note the relationship between the fetal tuberculosis and that of the infant and adult type. Ballantyne[12] states that fetal tuberculosis differs from infantile and adult tubercle in its characters, but the differences are such as can be explained by the general laws of antenatal as distinguished from postnatal pathology. In other words, fetal tuberculosis has peculiarities, not because it is tuberculosis, but because it is fetal. In the first place, fetal tubercle is not pulmonary tubercle. In the cases in which definite tuberculous lesions are present, they are rarely found in the lungs, and even when they are met with in these organs they are quite discrete. Evidently this is just what was to be expected, for the lungs are not in the direct line of bacillary invasion of the fetal body, neither is the circulation in the lungs at all active. On the other hand, the liver is in direct communication with the umbilical avenue of approach, and therefore it is to be expected that in it and the neighboring glands there will be tuberculous lesions. As a matter of fact, the liver is frequently affected, but it has to be noted that there are not a few exceptions. Possibly this is to be explained by the fact that the invading germs may pass directly to the heart by the ductus venosus without traversing the liver. From a study of the reported cases it would appear that tubercle germs may reach the fetus in large numbers. When they do so the lesions are generally widespread; they may, on the other hand, be few in number, and then the lesions are commonly localized. In the second place, the fetal tissues, far from being unsuitable soil for the growth of tubercle bacilli, are peculiarly fitted for their reception and development. In the third place, it may turn out that in the fetal tuberculous lesions giant cells are wanting, but in the absence of a large number of observations it is not safe to make this generalization. In the fourth place, tubercle bacilli may be present in the fetal organs in large numbers without the development of the characteristic lesions of postnatal tubercle; this is the so-called "bacillosis" without lesions, and it may be due to the termination of antenatal life before the lesions had time to form. In the fifth place, fetal tubercle may take on characteristics not at first recognizable as in any way tuberculous.

In discussing Baumgarten's theory, Ballantyne[12] further states that Baumgarten was struck by the fact which "has engaged many other workers in this field of study, that, while tuberculosis is evident and very frequently transmitted from parents to children, it is commonly not until in late childhood or early adult life that distinct signs and symptoms begin to appear. In order to retain the idea that the tubercle of the ascendants was transmitted to their descendants, and to bring it into harmony with the long period of apparent immunity which intervenes between birth and the appearance of the disease, Baumgarten was led to formulate the theory of the latency of the germ. He believed that the germs are carried to the unborn infant either through the placenta or by the ovum or spermatozoon (at the time of conception); that these sometimes, possibly when very numerous, set up distinct tuberculous lesions in the fetus or lead to the development of the rare infantile form of tuberculosis; that most of these are few in number and remain in the fetal tissues and organs in a larval state till succeeded by one of semi-activity in which tubercular foci are formed; and that these foci may long remain latent, existing simply in the anatomical and not in the clinical sense, but may at some time or another give rise to active tuberculous manifestations. It was thought that the tuberculous foci were most often to be found if looked for in the bones and glandular system.

"Now modern research has revealed some facts which lend support and some which go to discredit this theory of latency of the germ as stated by Baumgarten. For instance, it is known that the tubercle may, in small numbers at any rate, gain access to the fetus through the placenta, and that at the time of birth they may have produced no recognizable tuberculous lesions. On the other hand, there is little or no evidence to support the conclusion to which Baumgarten was driven, that the tissues of a fetus, on account of their great vitality, restrain or altogether prevent the growth of the germ of tubercle. There are other difficulties in the way of an acceptance of Baumgarten's theory, and it must be fully conceded that the great number of cases of tuberculosis both in children and adults, are caused by the invasion of the organism by germs in postnatal and not in antenatal life. The cases of true congenital tubercle, with or without lesions, are rare; and there is no good reason to believe that germs enter the fetus and after a period of latency lead to autoinfection in adult life."

In conclusion, I would state that it is evident that because of the peculiarities of the fetal circulation it is possible for the fetus to be infected directly from the maternal blood. A. S. Warthin[13] of Ann Arbor describes a case of miliary tuberculosis of the placenta in a woman suffering from incipent tuberculosis. Although no mention is made of the physical condition of the infant, the possibilities of infection are patent. To decide whether tuberculosis occurring in early infancy is the result of antenatal or postnatal transmission is a question always open to academic discussion. In the case just reported, we have no definite data at hand. The family history being negative, the physical examination of the child showing no evidences of tuberculosis, the Von Pirquet test giving a negative result, the report of the pathological findings, the primary isolation of infection to the testicle, all this being taken into consideration, I believe that one is justified in considering this a case of antenatal transmission.

I wish to express my thanks and appreciation to Dr. Frederic Kammerer, from whose service this case was submitted for publication.

## THE SIGNIFICANCE OF IRREGULAR UTERINE BLEEDING.*

By LEROY BROUN, M.D.,

NEW YORK,

SURGEON TO THE WOMAN'S HOSPITAL.

A PATIENT with any abnormality of her monthly uterine flow will in almost every instance consult her family physician for an explanation and for its relief. It is for him to be thoroughly alive to the varied causes of this common occurrence and to be able to direct the questioner with certainty in its treatment. You are already familiar with each condition, and there is nothing new in what I am bringing before you to-night either as to condition or treatment. I have thought, however, that it might be of some interest and of some possible value to review the subject as a whole in its varied correlations.

Periodical monthly bleeding in normal amount from the uterine mucosa and the postpartum flow from the placental site are natural. All other loss of blood is abnormal and must be looked on as having for its cause a pathological condition. It will suit our purposes for this discussion to divide these into classes, benign and malignant. Among the former we will find mucous polyps arising from the lining membrane of the body of the uterus or of its cervical canal. They consist of circumscribed hypertrophies of the endometrium and may be single or multiple. Their origin is not well understood yet they are known to most frequently exist in connection with other pathological conditions of the pelvic organs. Such a condition, however, occurs when no other apparent pathological condition exists. The surfaces of such polyps are very vascular and give rise to intermenstrual bleeding especially when protruding from the cervix and subjected to abrasion by the vaginal wall, douche pipe, or otherwise. At times the endometrium of the body of the uterus takes on a polypoid thickening giving rise to multiple polypi, chiefly of a sessile character. This

*Read before the West End Medical Society, October 25, 1913.

condition is especially found at the beginning of puberty and at times at the climacteric. Such a condition is characterized frequently by profuse hemorrhages. The treatment consists in the removal of the polyps by the clamp or otherwise when visible and by the curette from the body of the uterus. All curettings should be preserved and submitted to a thorough pathological examination to avoid the possibility of overlooking (especially in middle life and beyond) what might be carcinoma of the body of the uterus.

Erosion of the cervix is another though not a very common cause for intermenstrual bleeding. This may exist in nulliparous as well as multiparous women and has behind the condition a pathological state of the cervical glands, giving rise to irritating discharges by which the epithelium covering the cervix is destroyed. In multiparous women this is usually added to by the eversion of the mucous membrane of the cervical canal as a result of an ununited cervical tear. The bleeding in such instances usually follows contact. While this condition is within itself not serious, yet in some instances it so closely resembles and in others is the commencement of carcinoma of the cervix, that I am convinced that we should not attempt local treatment in the way of silver nitrate, astringent applications, and such like. This treatment is at best in the mildest cases of little avail, since we do not reach the cervical glands, the discharges from which are the origin of the trouble. The only satisfactory method in my hands is to divulse and curette thoroughly the cervical canal, following this by an application of nitrate of silver solution or iodine to the curetted canal. After this has been done the eroded area is excised and the healthy mucous membrane coapted by sutures, leaving no raw surfaces exposed. This line of treatment accomplishes two purposes: first, it cures the patient; secondly, the excised portion enables the pathologist to recognize the earliest presence of cancer of the cervix if such should exist.

Gonorrheal endocervicitis (acute) is another cause. Here the discharges are mucopurulent and at times are tinged with blood. The microscopical examination of the smear from the cervical discharges will demonstrate the nature of the condition and the treatment with argyrol and ichthyol on thin strips of gauze inserted daily into the cervical canal will relieve the condition.

Threatened miscarriage is a familiar cause of such bleeding. With the history of the absence of one or more menstruations together with a bimanual examination the presence of pregnancy is usually positive and the treatment clear. In instances of a retroverted uterus (a frequent cause for miscarriage) little can be learned from the bimanual examination in the first month of pregnancy. In the absence of the history we must depend on the pelvic examination. The source of blood in these instances is from the surface exposed by the partial separation of the placenta from its uterine attachment. The treatment is absolute rest in bed together with allaying the irritation of the uterus by medication in order to prevent a further separation of the placenta. In some cases this is successful, in others it is not. The retention within the uterus of placental tissue after a miscarriage also gives rise to the well-known irregular and frequently recurring bleeding. The blood may come in this instance from partial separation of the pieces of placenta from their uterine attachments, or from the placental tissue itself or from the vascular decidual tissue lining the uterus. A curettage is all that is needed.

It will be well to bear in mind also the possibility of the pressure of a hydatidiform mole, though such a condition is rare, occurring only in one out of 2,400 cases according to Williamson as quoted by Williams. Such condition should be suspected if frequent bleeding occurs in pregnancy, and if the uterus is much larger than it should be for the duration of the pregnancy.

Uterine bleeding as the result of extrauterine pregnancy must be differentiated from the bleeding from a uterus with the remnants of a miscarriage. This is not always so simple as it would appear to be, and especially so when the patient comes under observation for the first time with the history of having passed what she describes as membranes. In extrauterine pregnancy the uterus is slightly enlarged and its endometrium becomes thickened and engorged, constituting a decidual membrane. With the attendant bleeding, parts of this membrane may be thrown off and at times the entire membrane is discharged.

With such an occurrence the statement of the patient that she has had a miscarriage is certain to be made, and the error may be confirmed by the physician in the absence of the membrane and its examination unless he bears the possibility of such an occurrence in mind. Many patients have been curetted for just such conditions. The history backed up by a careful bimanual examination will usually make the diagnosis clear.

If the first examination does not give the satisfactory evidence, rest in bed with careful observation and examinations at intervals will clear up the point in question, so far as the differentiation between these two conditions is concerned. There are times, however, when the differentiation between extrauterine pregnancy and pathological inflammatory conditions of the uterine adnexa is difficult or even impossible. In both we may have the irregularity in the menstruation and the subsequent slight loss of blood continued over quite a period. In both we may have the intrapelvic mass mapped out by bimanual examination. In such conditions errors of diagnosis may be made, but not to the detriment of the patient since the condition calls for an operation in each instance.

Uterine bleeding prolonged and profuse at the menstrual time and often intermenstrual in character frequently has for its cause fibroid tumors of the uterus. When these tumors are subserous they do not give rise to disturbed menstrual functions. When, however, they are interstitial their presence act as a foreign body in the uterus, compressing the thin walled veins and venous sinuses, causing an obstruction to the return flow and a resultant congested condition of the endometrium. They thus give rise to a profuse menstrual flow, which at times by the squeezing out of blood from the engorged endometrium by the contraction of the uterus may be intermenstrual.

If, however, the intermenstrual feature is decided, the possibility of an associated carcinoma of the endometrium should be borne in mind, since this is known to occur in a little over 1.5 per cent. and should be an occasion for hastening the complete removal of the tumor and uterus.

I have attempted in this hurried review to call attention to the common causes of irregular bleeding in benign pathological conditions of the uterus, with which we are all familiar. There remains to

be considered the malignant changes in the cervix and the body of the uterus as the cause of bleeding. The importance of this symptom cannot be overestimated in these conditions for it is on account of this that the patient will consult the physician, and the responsibility is his to give careful heed to what she may regard as trivial and of which she may have only spoken in an incidental manner for the purpose of obtaining a douche.

Cancer of the cervix takes on two morphological characteristics: the one in which a cauliflower or spongy mass springs from one or both lips of the cervix and consists of an outgrowth of cancer cells surrounding a vascular center with poorly developed blood-vessels. From such a mass bleeding readily takes place, and necrotic masses will separate on account of ready disturbance in the circulation. This form is known as the everting or papillary kind. In the inverting or nodular character the disease is more of an ingrowth from the outset. Sooner or later the circulation of the periphery of the diseased area is disturbed by the extension of the underlying process and necrosis and bleeding result. Fortunately this usually takes place early; at times, however, the bleeding, the first sign attracting the notice of the patient, does not occur until the disease has extended beyond any hope of cure. This nodular type is prone to recur after removal.

The occurrence that should attract the attention of the patient and cause her to consult her physician is the appearance of a persistent leucorrheal discharge which has not previously existed. This discharge is later tinged at times with blood, especially on exertion. At other times the leucorrhea may not be so prominent, but the first evidence may be a slight recurring show of blood or a bloody discharge between periods, which is accentuated by the touch of a douche pipe or otherwise. The flow may amount to a sudden profuse hemorrhage, but more often the character is scanty, ceasing after a short time to recur at intervals on exercise or bending over. When such conditions occur at or near the age of the change of life it is too often mistaken for some of the attendant vagaries of this period, a distorted knowledge having been gathered by the younger generation of women from those who have gone before. Having absorbed such erroneous ideas she fails to seek advice until the disease has advanced beyond the earlier stages.

During the earlier stages the danger flag of pain is as a rule absent. This is only present in the more advanced stages, when the extensive exudate is pressing on the nerve ends. The erroneous conception is frequently held by women that nothing can be radically wrong in the pelvis if they do not have a feeling of discomfort and pain in this region. With the absence of pain and discomfort they attach no importance to an irregular show of blood, especially if this should occur at or about the period of their lives when all women expect irregularities.

Cancer of the body of the uterus from the standpoint of the patient has all the early symptoms of cancer of the cervix. They are irregular bleeding, a watery discharge which is at times dark colored and the same absence of pain as in the former instance. The above symptoms having been given us by the patient on her first consultation, it is our imperative duty to the patient to insist on a thorough local examination. The results of such an examination will give a full view of the cervix, and will enable the physician to state whether cancer is present or whether it is absent.

There are times when the involved area is doubtful. This is especially true in the earliest commencement of cervical cancer. Under such circumstances there is only one course to follow, that of speaking frankly to the patient or her relatives and urging that the diseased part shall be removed and submitted to a competent microscopist for examination. In general I think it best that when such an examination is needed the part in question should be removed under general anesthesia, preferably gas and oxygen, and at once a frozen section should be made and examined by a competent pathologist. This method of procedure has many advantages over removing for examination such a section under cocaine in the office. Chief among these are that such an office procedure opens up lymph channels of absorption carrying further up into the uterus the cancerous juices if cancer should be present. And again it is not always easy to get a proper section of a questionable cervical area under local anesthesia in the office. If the examination proves that cancer is not present, the patient being still under anesthesia can be given the benefit of having a repair of the cervix made, of which she was evidently in need.

If the office examination shows that no disease of the neck of the uterus exists, the examination must be extended to the inside of the body of the uterus to prove or disprove the presence of cancer of this part. This examination should not be done in the office. It should be done under an anesthetic with all surgical care. Under the anesthetic the uterus may be found to be a little larger than normal. The scrapings from the inside of the uterus are saved and submitted to the pathologist for diagnosis. Many times the diagnosis of cancer is at once evident from the abundant brain-like material drawn away; at other times the decision of the pathologist must be awaited.

The importance of a thorough determination of the cause of all irregular uterine bleeding cannot but be impressed upon us when we know that between the ages of 45 and 64 one out of every eleven deaths among women is due to cancer of the uterus and the breast, of which deaths two-thirds are from cancer of the uterus. Knowing that all cancer in its earlier stages is a local disease, and as such can be cured, makes the responsibility doubly imperative that we recognize whenever possible the condition at a time when something of value can be done.

In a collection of all the cases of cancer of the uterus who have entered the Woman's Hospital during the last six years, comprising patients who have been sent there in the hope that something could be done, there were 86 patients with cancer of the cervix; 21, or less than one-fourth, were discharged as possibly cured, such an operation having been done as to insure every possibility of there being no return of the disease. The remainder could only be given palliative treatment. Of the 125 cases of cancer of the body of the uterus, 41, or about one-third, were discharged as cured. Among the remainder the disease had existed for such a length of time as to have extended beyond the uterus and to have involved other organs. This is a discouraging report, and especially so when we recognize that in cancer of the body of the uterus the disease is of such slow progress that even though it may have existed for some time it is still confined to the uterus and we expect to cure almost every patient.

The experience in all clinics in America is that

it is rare that more than one out of every four who apply with cancer of the uterus can be given any treatment other than something to ease their pain and make their short period of life more bearable. This same discouraging lack of self-care existed in Germany and elsewhere abroad prior to ten years ago. Winter keenly appreciated this fact and undertook a personal campaign of education on the subject of cancer in 1902 after moving to Konigsburg, Prussia. These educational efforts of Winter with the hearty support of other medical centers have brought about on the continent a marked change since 1890. The percentage of patients applying for relief in the early stages has been doubled. A similar percentage increase is seen in the patients sent to hospitals by midwives.

Such a system of education can only be productive of the greatest good and has been felt throughout all of the continental hospitals, where in nine of the largest 60 per cent. of the patients applying for relief have come sufficiently early to be given the opportunity of a permanent cure. This may be in part due to the extension of the field of operation. I believe, however, that the education of the people has had most to do with this change.

There has been lately formed an association known as the American Society for the Control of Cancer. This society has the endorsement of the national associations making up the American Congress of Physicians and Surgeons, and of the American Medical Association. It has upon its board of trustees prominent lay people, both men and women, together with physicians and surgeons throughout America. Its membership is open to all who may wish to help in educating men and women for their own protection. The objects of this society are many. Lay people will be informed through the daily press and through periodicals and by lectures of the necessity and of the importance of consulting their physicians on all matters in which there are departures from what is normal. The physician and busy general practitioner will have it frequently impressed upon him that all cancers have a small beginning, and as such their significance may be overlooked unless studied, and definitely proven not to be of such a nature. The scientific side of the problem will also be undertaken in collecting reliable data and determining as far as it is possible the comparative value of the old and the recurring new methods of treatment.

The Associated Gynecological Clinics of New York City at a recent meeting adopted the following short synopsis for the purpose of educating the poor upon the subject of cancer of the uterus. They recommended to the Board of Associated Out-Patient Clinics of New York City that this synopsis be printed on a card and be given to every woman patient of all the clinics of this city.

*"Cancer of the Womb.*—Cancer of the womb can be cured in the early stages. Prolonged or irregular monthly flow is frequently the first sign of this disease. Slight bleeding after a douche, or sexual intercourse, is one of the earliest signs. After the age of 30 any of the above occurrences should demand an immediate local examination of the internal organs by a competent physician. There is no pain with cancer in its beginning. Profuse bleeding and frequent spotting is not the sign of change of life. It may mean cancer."

I believe that such a course of systematic education will be the means of saving many lives.

148 West Seventy-seventh Street.

## VENOUS CIRCULATION.

By S. MILES ROBINSON, M.D.,

Orlando, Fla.

What are the physical forces involved in venous circulation, according to the accepted theory, and are they adequate to perform the work with which they are credited? At a glance it is evident that venous circulation is dependent for its maintenance upon forces very different from those that control arterial circulation. We find, as the initial force of arterial circulation, an engine of great power, perfectly adapted to its work, performing that work continuously with great mechanical precision. Its propelling power is transmitted throughout the whole arterial system, but gradually diminishes as the distance from the engine increases so that we have the highest blood pressure in the largest arteries nearest the heart and the lowest in the capillaries at the periphery. But when we come to the termination of the arterial system and the beginning of the venous system, and contemplate the factors which make for the return of the blood from the extremities to the heart, we find a very different state of affairs.

The blood which in the arteries is propelled for the most part in harmony with the laws of gravitation, in the veins travels for the most part in opposition to those laws. Instead of a propelling heart engine to drive the blood in pulsing waves through the vessels, we find but an indirect effect of heart action questionable as to its constancy and force. We find a lessening number of vessels of increasing caliber but decreasing capacity (although that capacity remains twice or thrice that of the arteries) instead of an increasing number of decreasing caliber and increasing capacity, as in the arterial system. The vessels also differ greatly in their construction although histologically similar. The walls of the veins instead of being elastic and resilient are comparatively weak and yielding, and the majority of them are furnished with delicate valves, which, opening toward the heart, permit the blood to flow in that direction only.

According to the generally accepted theory three principal factors maintain the return flow of blood. These are: First, a sort of residue of pressure transmitted from the arterioles through the arterial capillaries to the venous capillaries, which drives the blood upward toward the heart and the lower pressure of the larger veins. This is the factor above referred to as being of questionable constancy and force, and is known as the "vis a tergo," or force behind. Secondly, a pressure exerted by the muscles in action. The bellying of the muscle as it contracts must necessarily exert considerable pressure upon the veins in its immediate neighborhood, and this pressure, with the cooperation of the valves, tends to empty the veins heartward with each muscular contraction. Thirdly, the "vis a fronte," an effect of thoracic action, or, to quote Kirke, "the suction action of the heart and the aspiratory action of the thorax."

It is the purpose of this brief consideration of the subject to question the efficiency of these three factors, to call attention to their relative importance and to point out another factor which, mechanically, may be better adapted to the work; and inasmuch as many, if not most, circulatory disturbances are venous, to suggest the possibility of utilizing this factor for their relief.

Vis a tergo, as a factor in venous circulation is,

as already described, a transmission of the residue of arterial pressure to the blood in the venous capillaries. Is it indispensable to venous circulation? If so, its relative importance is high; but, as indicating that it is not indispensable, the following is to be cited: It is a well-known fact that the condition of circulation which prevails in gangrene is one of stasis—a stoppage of the movement of the blood in the capillaries of the part; and this may be due to either venous or arterial obstruction. When the obstruction is arterial the form of gangrene developed is known as "dry gangrene." The venous blood is carried away from the part while the arterial blood is prevented from reaching it and the tissues shrink and shrivel up. Here is a condition where vis a tergo has been entirely eliminated as a factor in venous circulation. The arterial obstruction has prevented the transmission of the heart's force to the venous capillaries and yet the venous blood leaves the part, to large extent, at least, and continues its journey to the heart. In the lesion known as moist gangrene the obstruction is venous and we have just the opposite condition. If, for the sake of the argument, we ignore for the time being the force behind, which we have just seen may be inoperative without a corresponding suspension of venous circulation, we have left two of the main factors in the maintenance of the venous flow, namely, muscular pressure and thoracic suction.

As already stated, the effect of muscular pressure to move the blood back to the heart depends upon the activity of the muscles. Then it follows that if the muscles are inactive they cease to be of importance. Nearly one-third of the life of man is spent in muscular inactivity, and yet, so far from this causing a condition of imperfect venous circulation during sleep it is, if anything, in the normal body, actually improved. It might be well to note in passing that the lymphatic circulation, which corresponds very closely to the venous, its vessels being supplied with many valves and its stream moving toward the heart under somewhat similar conditions, is largely dependent upon muscular activity for its maintenance and this does show imperfect function during the sleeping hours, the extremities being usually somewhat larger, that is to say, somewhat more swollen, after hours of sleep; and this has been found to be accompanied by engorgement of the lymph channels. The inference is fair that, were the venous circulation equally influenced by muscular action, there would be a similar condition of engorgement of the veins after a night's rest. If now, we may for the time being, consider muscular activity as a factor of venous circulation, to be in the same category with the "force behind," that is, relegated to the domain of the questionable, we have left to our consideration but one factor, the vis a fronte—"the suction action of the heart and the aspiratory action of the thorax." But does the aspiratory action of the thorax exert any notable effect upon the venous circulation? This question would seem to be partially answered by the statement that a cessation of thoracic movement, as in holding the breath, does not seem to produce any marked effect on the normal heart. If the venous blood were thereby retarded in its flow heartward, a very noticeable change in the heart action should result —the heart cannot pay out more than it receives— and if such suspension of breathing were only briefly maintained there should be a noticeable engorgement of the superficial veins. But this does not seem to occur in the normal body; at least the suspension cannot, apparently, be sufficiently long maintained to produce that effect, or, indeed, any other analagous thereto. Part of the vis a fronte, according to Kirke, is the sucking action of the heart itself. We can imagine a man lying perfectly motionless upon a bed, holding his breath for one minute. Two of the factors of venous circulation have, for the time being, suspended their action. Muscular pressure is nil, so is the aspiratory action of the thorax. Then the vis a tergo and the sucking action of the heart are the only forces left in operation. How much of the blood is pulled back to the heart by its own sucking action? The force exerted by the auricular walls upon the venous blood column, we are told by Kirke, is "assisted by the elastic contraction of the lungs. The lungs being in a closed cavity, the thorax, and being distended with air are in virtue of their elasticity always tending to recoil and squeeze the air out of their interior. In so doing they drag upon any other organ with which their surface is in contact; this elastic contraction will be greatest when the lungs are most distended, that is, during inspiration, and will be more felt by the thin-walled auricles than by the thick-walled ventricles of the heart." This makes part, at least, of the heart suction to depend on lung action. But we have already seen that a cessation of lung action is possible without noticeable effect upon the venous circulation; therefore the assistance rendered the auricles by the elastic lung tissue may momentarily be reduced to nothing, and whatever effect heart suction has depends, under the conditions we have imagined, upon the pulling power of the thin-walled auricles alone. This effect is limited to auricular diastole for, to quote Kirke again, "the reason why the blood does not pass backward into the veins with auricular systole but onward into the ventricles is again a question of pressure; the pressure in the relaxed ventricles * * * is less than in the veins. * * * Though there is no regurgitation of the blood backward into the veins, there is stagnation of the flow onward to the auricles." This being all that is left of the sucking action of the heart (still referring to the hypothetical condition) it would seem impossible that so weak a force as the suction of thin-walled auricles in diastole would be adequate to exert much effect upon the blood stream to draw it through its myriad tortuous channels back to its "pitcher at the fountain."

Briefly to epitomize our conclusions: (1) Vis a tergo is not indispensable to venous circulation because it may be nullified by arterial obstruction, as in dry gangrene where the blood is carried by the veins away from the part affected. (2) Muscular action is not indispensable because it may and does cease each day for a greater or less length of time without any bad effect upon the circulation. (3) Vis a fronte, consisting of lung suction and heart suction, while it may not be entirely eliminated, may be so reduced in its effect by cessation of respiration as that it dwindles to the mere pumping power of thin-walled auricles during diastole upon the venous blood column, the adequacy of which power being, at least, questionable. (4) A subject in the horizontal position, holding his breath for one minute, has eliminated all factors of venous circulation save two, vis a tergo and the suction of the auricular walls during diastole, and yet no appreciable disturbance of venous circulation is apparent at the end of that minute.

We will now proceed to the consideration of a factor possibly more potent than any of those thus far discussed. Most of the large arteries of the body are accompanied in their course by one or more veins lying close beside the artery and in contact with it by an intervening structure of connective tissue and encompassed by a common sheath. This sheath is a non-elastic fascial structure. It binds the artery and vein together, not tightly—at least not in the cadaver—but sufficiently closely to produce the mechanical effect now to be considered. When the pulse-wave originating in the heart-systole thrills through the blood vessels and the arteries dilate under its pressure the vessel sheath does not yield. Both artery and vein are full of blood. The dilatation of the artery, pressing laterally toward the vein, displaces the intervening connective tissue and presses in the side wall of the vein. The liquid contents of the vein, under this force, have but one thing to do. They must get out of the way. To do this they must move heartward for the simple reason that they cannot move in the opposite direction, being prevented from so doing by the venous valves. Each heart throb, then, not only propels the arterial blood directly toward the extremities, but, by a force, indirect, it is true, but almost as vigorous, it drives the venous blood through the attendant veins back toward itself.

It matters not that some of the veins have no valves; the frequent anastomoses of these vessels draws from the veins not supplied with valves into those which are. Neither does it matter that certain large superficial veins do not accompany arteries, as the long saphenous, cephalic, etc. (Here we must concede greater importance to muscular activity and external contact pressure, even though we may still question the cardinal value of vis a tergo and thoracic suction.) The dilatation of an artery under the force of the pulse wave exerts a pressive effect upon its accompanying vein, but its action is not limited to this effect. The space between the artery and vein in the sheath is filled with connective tissue binding them together side by side, while the sheath binds them together externally. When the artery recoils after its expansion, the walls of the vein must go with it, and the vein is thus dilated again by a force which is not that of its own weak walls, but of the stronger walls of the artery. Thus the artery performs a positive pumping action, not only pressing the blood out of that portion of the vein against which it expands, but drawing it in from below and filling the vein again with each recoil. This action by anastomosis affects the contents of all the contiguous veins and the superficial veins may thus be emptied of their blood by the suction pump action of the arterial walls. Furthermore, contact of vein and artery in a common sheath does not need to be for the entire length of the vessels. A few inches anywhere along their course would suffice to keep the blood moving, for any extent of the two ensheathed vessels between valves would act as a suction force pump in the course of the blood flow. In respect of the capillaries and the veins less than one line in diameter, which have no valves, the reduction of blood pressure on the venous side of the capillaries caused by the arterial suction emptying the veins heartward, is quite sufficient to cause a steady flow through these lesser channels, as manifest in the condition of dry gangrene above cited. It is only necessary, then, that a certain proportion of the medium sized veins should be supplied with valves and accompanied by expanding arteries in a non-elastic sheath, to provide for the venous circulation a positive and constant factor making for uninterruped movement, independent, in greater or less degree, of all other factors and conditions save the heart action itself.

Now let us glance at a few facts tending to substantiate this theory. We will first consider those which seem to invalidate the vis a tergo—muscular action—thoracic suction theory.

I. Arterial obstruction produces dry gangrene and destroys the force behind, but it has no effect upon the lateral action of the arteries upon the veins above the line of demarcation, therefore the venous blood leaves the part, although the arterial blood may not reach it.

II. Muscular quiescence, so far from diminishing the venous flow, as it should do, according to the theory which in part depends upon it, increases it by allowing more room for the expansion of those arteries ensheathed with veins, and this would account for the fact that the circulation is usually better during absolute rest. This argument does not lose sight of the fact that exercise quickens circulation; but this effect is not produced by the more rapid return of the blood to the heart by reason of greater or more frequent muscular contraction, but rather the increased heart action induced by accelerated catabolic metabolism resulting from the exercise.

III. Thoracic suction, as already shown, is not without some effect upon venous circulation, but that effect is limited to the recoil of the thin-walled auricles during diastole. This might, in fact, be sufficient to lift the blood for the last few inches of its journey through the inferior vena cava.

IV. The placental circulation furnishes some characteristic peculiarities which seem to bear upon the matter. Here we have a condition of circulation differing from all others. From the placenta the blood moves by way of the umbilical vein into the fetal body. For its movement what are the forces engaged? Surely "thoracic suction" on the part of the fetus must be almost nil, for the blood reaching the fetal body is, for the most part, emptied into the liver and distributed throughout its interlobular capillaries where the sucking action of the thin-walled right auricle in diastole would seem to be very slight. Vis a tergo in the placenta, while probably as potent a factor as it is in the systemic circulation, is at least no more so, inasmuch as the blood in these vessels is found to be under about the same pressure as the maternal blood in the intervillous spaces. Of course we have little or no muscular action to consider in this instance except the rhythmic contractions of the uterus which may affect the pressure in the placenta, but these are too infrequent throughout the greater part of the period of gestation to be considered an important influence. But we do have the umbilical vein tightly wrapped around again and again by two vigorously pulsating arteries and no outlet for the blood thus subjected to pressure but the direction of the fetal body. It is true that the umbilical vein itself is valveless, but retrogression of the flow would be against the pressure of the arteries transmitted through the placental capillaries (the vis a tergo), and this must be greater than the pressure in the portal system of the fetus inasmuch as it equals the capillary pressure of the maternal blood in the intervillous spaces, as above pointed out; and this

is as fifteen or twenty in the capillaries to ten in the portal vein.

V. It is accepted as a truism that a man is as old as his arteries. But why should this be true if the circulatory processes are dependent upon capillary pressure (vis a tergo) muscular activity and thoracic suction? Only one of these three factors need be materially affected by the passing years. Surely thoracic suction and muscular activity would not necessarily be much different at forty from what they were at twenty. The answer to the question lies in the fact that the pathological condition found in the arteries is that of hardening, which means loss of expansibility. The sclerosed arteries do not dilate and contract to the pressure wave in the man of fifty to the same extent as in the younger man, consequently the veins receive less lateral pressure with each heart beat. The heart action, as to its frequency and power, may be the same as in the younger years, or even greater, as witness the high blood pressure usually accompanying arteriosclerosis, but the force transmitted to the attendant vein is so reduced by the lessened excursion of the arterial walls that venous sluggishness, functional disturbances and trophic changes are inevitable.

VI. Another notable fact is worthy of consideration in this connection, viz., increase in the power of the heart's systole, a physiological effect of digitalis, is followed by decrease in venous pressure. It should increase it if the "force behind" is an important factor. Its real effect, however, is to augment the expansion of the arterial walls and thus accelerate the movement of the blood heartward and relieve the venous engorgement.

A few suggestions may be offered as to the possibility of utilizing the facts cited in support of this theory, if they be facts.

I. In cases of sluggish venous circulation in the extremities, evidenced by edema of the ankles (in the early stages of cardiac dropsy) might it not be possible to relieve this sluggishness of movement by exposing the femoral artery and its vein for the entire length of Scarpa's triangle and Hunter's canal and taking a reef in the enveloping sheath, thus bringing them into closer contact and securing a greater effect upon the vein from the pulse-wave expansion of the artery? The acceleration of venous movement thus achieved, although very slight, might be sufficient to relieve the engorgement lower down and postpone for some time the seriousness of that symptom.

II. The same operation might greatly relieve varicose veins in the lower extremities by reducing somewhat the pressure on the walls of the long saphenous, as a result of moving more blood through the femoral vein. It is usually the case that varicose veins make their appearance, where not due to mechanical obstruction, in those years when sclerosis of the arteries has become an important factor in circulatory disturbances.

III. Again, where general sluggishness of the venous circulation, with coldness and edema of the extremities and degenerative changes prevail as a result of arteriosclerosis, such a reefing of the femoral sheath might be duplicated in respect of the brachial and popliteal vessels with the result that the blood would flow back to the heart and lungs with greater freedom, oxygenation and metabolism be accelerated, dyspnea relieved, and bodily vigor thus conserved.

IV. The terminal condition in those heart lesions in which venous stagnation, due to broken compensation, is most marked, is one of highly augmented venous pressure, to the point where, as in the case of the umbilical vein under the effect of post-partum uterine contraction, arterial pressure is no greater, or is even less than, that in the veins and circulation ceases. Might not such an operation as that above suggested upon the vessel sheaths, where accessible, by accelerating the venous movement, relieve the stagnation and defer the termination? It is possible that in such a condition heart stoppage is not due to heart weakness, that organ being sometimes enormously hypertrophied, but to failure of the blood supply to its chambers.

---

## CLINICAL STUDY OF A CASE OF CHRONIC INTESTINAL TOXEMIA OF SEVERE TYPE.

By EDWARD E. CORNWALL, M.D.,

BROOKLYN, NEW YORK.

ATTENDING PHYSICIAN TO THE WILLIAMSBURGH AND NORWEGIAN HOSPITALS; CONSULTING PHYSICIAN TO THE BETHANY HOSPITAL

W. H. B. is a man 50 years old, of American birth and parentage. His father is still living and in good health at the age of 73. His mother died at the age of 51 from strangulated hernia, but for a number of years before her death she suffered from arthritis deformans with enlargement and crippling of the smaller joints of the extremities. His maternal grandmother, who died at 65, also suffered from arthritis deformans to such an extent that she was unable to walk for eight years before her death. Since the age of nineteen he has lived a largely sedentary life, as keeper of a retail store. He has never taken alcohol or tobacco, and has been moderate in his use of tea and coffee. His diet has been the conventional one. He had lobar pneumonia at the age of fifteen, but no other acute disease of consequence or any bearing on his present condition. As far back as he can remember he has been constipated. During the past twenty-five years or more he has suffered from what he calls "bilious headaches." These headaches occurred at intervals of a few weeks, usually about five or six, until the early part of the year 1910, when they became more frequent. They increased in frequency until, in October, 1910, they became continuous. And along with this severe headache he developed the following symptoms: weakness, dizziness, palpitation, bad taste in the mouth, pain in the back of the neck, and a constant and distressing dry cough. His weight, which was normally 155 pounds, fell to 135 pounds.

He first consulted me on October 10, 1910. Physical examination then showed him to be poorly nourished, with a sallow, muddy complexion, slightly jaundiced conjunctivæ, and a coated tongue. Examination of his lungs, heart, and abdomen was negative. Examination of his urine was negative. His systolic blood pressure was 120 mm. Hg. He was put on a non-putrefactive and laxative diet, arranged to supply daily about 70 grams of protein and fuel of the value of 2,300 calories; and he was also ordered a laxative tablet to be taken nightly until he no longer needed it. Details of this diet are given farther on. Two days after he began this diet the headache, dizziness, palpitation, pain in the neck and cough disappeared, and recovery of strength followed. The constipation greatly improved, being controlled, after two months, by a diet

alone and an occasional laxative. He gradually regained most of his lost weight, and at the end of one year weighed 146 pounds. His appearance improved and his muscular endurance became greater than it was formerly when he was eating the conventional diet, though he had less energy.

Although his continuous toxemic symptoms disappeared and he was in good general condition, he still suffered from periodical attacks which suggested a cyclic toxemia. Regarding these cyclic disturbances he made the following observations: (1) *The length of the cyclic periods.*—During the first two years, or until about January, 1913, the toxemic disturbances occurred every fifth or sixth day; but after January, 1913, the intervals between them lengthened, so that now they occur about every two weeks. (2) *Symptoms connected with the stools.*—Although the bowel movements during practically the entire period since first coming under treatment were normal in frequency, though less in quantity than when he was on the conventional diet, the cyclic disturbances during the first two years were preceded by a change in the color of the stools: the stools became lighter as the time for the disturbance approached and were a light yellow when the subjective symptoms developed. During the last six months these changes in color have not been noticed. The odor of the stools was not offensive between the cyclic paroxysms, nor at the time of their occurrence; but after taking a saline laxative, which is his regular treatment for the paroxysm, the resulting movement was extremely offensive. When the saline laxative failed promptly and completely to abate the toxemic symptoms, and these symptoms lingered over into the following day, disappearing then gradually, which happened about every fifth or sixth time, the natural movement on the second day following the saline was more foul smelling than the saline movement. Once in about every three months the regular periodical treatment with the saline failed to ablate the toxemic symptoms and then relief was secured by a large dose of a vegetable cathartic. Usually, however, vegetable cathartics proved much less effective than the saline for the purpose, and a large dose of the saline taken in the morning was less effective than a small dose taken at night. The saline which he employed regularly was one teaspoonful of magnesium sulphate in one-third of a glass of hot water on retiring. (3) *Subjective symptoms at the time of the cyclic paroxysms.*—The first symptoms noted were regularly dizziness and palpitation, to be soon followed by pain in the back of the neck, headache, dry cough, and a feeling of slight air hunger. During the past year he has noticed as a very early symptom of the impending paroxysm, a desire to drink water often in small quantities, followed in about twenty minutes by a desire to urinate. These subjective symptoms grew steadily worse until he cleared his bowels, which he never long neglected to do after the first intimation of the oncoming of the paroxysm; in fact, he has never put off doing so more than one day. He has found that he can excite similar symptoms by unusual physical exertion, especially by nodding his head or looking around quickly, as well as by getting excited or agitated, and once similar symptoms were brought on by exposure for about an hour to the fumes of many automobiles in a crowded course. Three times during the first year of treatment he precipitated a paroxysm by eating a piece of meat. During the last three months he had three attacks in the day time, characterized by a sudden peculiar sensation starting in the right side of his head, about one and a half inches above his right temple, which flashed backward about four inches in a zigzag manner. This sensation he describes as a "feeling as if a lump were forced through a tube in his brain." It lasted only an instant, and was followed by a feeling as if the whole right side of his head was burning, which soon passed away. On each of the occasions when these attacks occurred he had delayed to take his customary dose of salts for one day after the first intimation of the onset of a cyclic paroxysm. Twice he fainted during a paroxysm. An examination of his urine was made at the time of a cyclic paroxysm, in the middle of the first year of treatment, with a negative result.

For three years this patient has taken a nonputrefactive and laxative diet, which supplied him a daily average of about 67 grams of protein and 2,240 calories; and he now finds himself (October 10, 1913) in very fair general condition. He has no unpleasant symptoms outside of the paroxysmal attacks; he feels better than he has felt at any time during the past three years; he has a good appetite, and his sense of taste is much keener than it was formerly, and he can do his work as well as ever, though he cannot hurry.

A physical examination made on July 18, 1913, when he showed no symptom of the cyclic disturbance, resulted as follows: moderately well nourished; color fairly good; clear conjunctivæ; tongue slightly coated; heart and lungs negative; liver dullness, one-half inch below normal; pulse rate, 80; systolic blood pressure, 110 mm. Hg., and diastolic, 70 mm. Hg. An examination of his urine on the same date resulted as follows: 2,400 c.c.; acid, sp. gr., 1,020; no albumin or sugar found; indican test negative; total urea, 23 grams; microscopical sediment contains many amorphous urates, many phosphate crystals, many epithelial cells, and many bacteria. An examination of his urine on September 11, 1913, when he was in the midst of a cyclic attack, resulted as follows: 1,700 c.c.; slightly acid; no albumin or sugar found; indican test negative; total urea, 20 grams. An examination of his blood on July 18, 1913, when he showed no signs of the cyclic disturbance, resulted as follows: Hemoglobin, 98 per cent. erythrocytes, 5,200,000; leucocytes, 6,000; many blood platelets. Differential count: polymorphonuclears, 55 per cent.; lymphocytes, 40 per cent.; large mononuclears, 2 per cent.; eosinophiles, 1 per cent.; mast cells, 1 per cent.; transitionals, 1 per cent. An examination of his blood on September 11, 1913, when he was in the midst of a cyclic attack, resulted as follows: Leucocytes, 12,000; polymorphonuclears, 75.3 per cent.; lymphocytes, 20.8 per cent.; large mononuclears, 6 per cent.; eosinophiles, 1.3 per cent.; mast cells, 1.3 per cent.; transitionals, 7 per cent.

On September 11, 1913, when in the midst of a cyclic attack, his blood pressure was found to be: systolic, 170 mm. Hg.; diastolic, 110 mm. Hg. His pulse rate was then 60. The nitroglycerin test was tried on him by giving one one-hundredth of a grain of nitroglycerin under the tongue with the following result. His subjective symptoms (previously described) became very much worse, he became faint and nearly lost consciousness; his skin became cold and clammy; his pulse rate fell to 36, and his pulse itself became so soft as to be almost imperceptible to the finger. This exagger-

ated response to the nitroglycerin test passed away in less than half an hour after prompt administration of strychnine and aromatic spirits of ammonia.

The dietetic prescription which was given to him on October 10, 1910, to be taken until further orders, was as follows: *Breakfast:* Any fresh fruit that agrees except berries; also prunes; 2 ounces of dry cereal or 8 ounces of cooked cereal, with milk, cream or butter; 2 ounces of bread with butter; a cup of weak tea or coffee if desired; 8 ounces of milk. *Dinner:* Four ounces of bread with butter; 6 ounces of potato; green vegetables freely from the following list: spinach, lettuce, green peas, green corn, string beans, squash, carrot, and (sparingly) tomato; raw cabbage; 1 to 3 ounces of cream or pot cheese; 1 ounce of rice or macaroni, boiled, with milk or butter; ½ ounce of American cheese if desired; 1 ounce of bacon if desired; small portion of a simple pudding or of ice cream occasionally if desired. *Supper:* Three ounces of bread with butter; 1 to 2 ounces of cream or pot cheese if desired; raw cabbage. *Additions and Substitutions:* Extra milk may be taken in addition, or it may be substituted for part of the bread ration. *Prohibitions:* Everything not on the above list, or included in it by implication, is absolutely prohibited; cane sugar, vinegar, spices, animal flesh, except that which is present in the small portion of bacon allowed, broths made from animal flesh, vegetables difficult of digestion, and fruits difficult of digestion or containing oxalic acid, are specifically as well as generally prohibited.

He has taken this dietetic prescription, with slight modifications, for nearly three years. During one continuous year, from August 6, 1911, to August 5, 1912, he kept an accurate record of all the food which he actually ate. This record shows that he varied his rations from day to day and from month to month, the latter with the seasons, the general average, however, being close to the quantities originally prescribed. Below is given his daily averages for each month of the year of observation ending August 5, 1912:

| | Protein (grams | Calories |
|---|---|---|
| 1911 | | |
| August (6th to 31st) | 66.46 | 2079 |
| September | 66.32 | 2010 |
| October | 68.28 | 2140 |
| November | 69.92 | 2190 |
| December | 74.11 | 2319 |
| 1912 | | |
| January | 75.32 | 2404 |
| February | 71.48 | 2300 |
| March | 64.45 | 2152 |
| April | 67.36 | 2196 |
| May | 61.28 | 2096 |
| June | 57.01 | 2111 |
| July | 61.99 | 2190 |
| August (1st to 5th) | 66.24 | 2255 |

His daily protein ration for the entire year ending August 5, 1912, averaged 67 grams, and his average daily fuel ration had a value of 2,240 calories.

This case presents a number of interesting and suggestive points, among which are the following: (1) The patient gave a marked family history of arthritis deformans. (2) He gave a personal history of a sedentary occupation, of constipation, and of periodical headaches for many years previous to the onset of continuous symptoms. (3) He obtained relief from his continuous and characteristic symptoms by a diet in which the protein derived from animal tissues was scarcely 5 per cent. of the total protein, and in which nearly all of the protein was derived from bread, cereals, milk, and cheese; in which the protein ration was kept at a daily average of about 67 grams, and the fuel ration at a daily average of 2,240 calories; from which cane sugar was particularly excluded, and in which was included a considerable amount of the cellulose of green vegetables. (4) He increased both his protein and fuel rations in the months of December, January and February, and diminished them in the other months. (5) He maintained good general health on this diet and gained in weight and had more endurance than when eating his former conventional diet, but was less energetic and slower in his movements than formerly. Query: Can it be that the protein and fuel rations above mentioned (allowing for percentages not absorbed) are near the minimum health rations for a man of medium size doing very light work? (6) Since taking this diet the keenness of his sense of taste has increased. (7) Although his continuous symptoms disappeared after taking this diet, and his general condition greatly improved, he continued to have periodical attacks with symptoms suggesting cyclic accumulations of intestinal toxins in the blood or cyclic disturbances of the liver. (8) Symptoms resembling those of these cyclic disturbances could be brought on by eating animal flesh, by unusual physical exertion and by excitement. (9) His stools became light yellow in color at the time of the cyclic disturbances during the first two years of the period of observation, but were nearly normal in color after that period. (10) His stools were noticeably offensive in odor only at the time of the cyclic disturbances, after a laxative. (11) His stools were smaller in total quantity while taking the non-putrefactive, anti-constipation diet than formerly when taking the conventional diet. (12) Indicanuria was not a noticeable symptom either at the time of his cyclic disturbances or in the intervals between them. (13) A small dose of a saline laxative taken at night was usually effective in promptly removing the symptoms of his cyclic disturbances. A larger dose of the same saline when taken in the morning was less effective. Vegetable cathartics were generally less effective than salines, though occasionally when the salines failed absolutely to abate the toxemic symptoms, which happened periodically, a large dose of a vegetable cathartic proved effective for that purpose. (14) Raw cabbage, eaten daily, was of great assistance in overcoming his habitual constipation. (15) His blood pressure was raised by the cyclic disturbances. (16) After two years of a non-putrefactive anticonstipation diet the periods between his cyclic disturbances lengthened.

## TYPHOID SPINE.

### WITH REPORT OF A CASE COMPLICATED BY THROMBOPHLEBITIS OF THE LEFT FEMORAL VEIN.

By COURSEN BAXTER CONKLIN, M.D.,

WASHINGTON, D. C.

ASSOCIATE IN MEDICINE, THE GEORGE WASHINGTON UNIVERSITY; ASSOCIATE PHYSICIAN TO THE GEORGE WASHINGTON UNIVERSITY HOSPITAL.

THE ravages of the typhoid infection unfortunately do not cease with causing complications of the gravest moment, but sequelæ often occur, which the patient is only too ill prepared to withstand. The spine appears to be relatively more fortunate in escaping than other structures. It will suffice to quote Halpenny's statistics read before the Inter-

national Medical Congress held at Budapest, to show the rarity of spine involvement. After a diligent search of the literature he was able to find only seventy-two cases. A. Frick, writing in 1910, increased the number to eighty. Analysis of the cases collected by Halpenny, Frick, Lord, Silver, and others yields the following data:

Males appear to be more frequently attacked, about 75 per cent. of the cases reported being of that sex. Trauma often acts in a predisposing role. The Eberth bacillus is the exciting agent.

The Germans speak of the condition as a spondylitis, while on the other hand Gibney uses the word perispondylitis to make plain his views concerning the pathology. T. C. McCrae, through radiographs, has demonstrated lesions of the vertebræ. This would seem to be confirmatory of the German idea. Osler departs from both of the above conclusions, claiming that the sequela is a neurosis and that there occurs a purely functional disturbance with no organic lesions.

Pain is a symptom constantly noted and it may be described as being atrocious in character. The lumbar region is usually the seat of the greatest pain, which at times may radiate down the limbs. Pronounced rigidity of the muscles along the lower spine often accompanies. Concomitant nervous manifestations at times noted are muscular twitchings, hyperemotional excitability, and dermatographia. Two cases have been reported, which had a persistent Kernig's sign. In a few instances muscular atrophy has resulted from the neuropathy. Deformities, such as lordosis and kyphosis have followed. It is worthy of note that painful tumefaction with actual pus formation is rare.

Recovery is the rule. Of twenty-one cases analyzed by Cutler, fifteen days was the shortest duration and thirteen months the longest.

The treatment advised by the various authors is, medicinally, nervous sedatives, as the bromides and valerianates; mechanically, immobilization. This has been accomplished by adhesive plaster, plaster bandages, and leather or metal supports. Counter-irritation by blistering with the thermocautery, as originally recommended by Gibney, has often seemed to give relief.

My case, which is rather unique in that it was accompanied by a thrombophlebitis, follows:

G. A.; male; white; age, twenty-five; single, occupation, clerk.

Family history, unimportant.

Previous History.—Health usually good; denies excesses of all kinds; no venereal history; made a trip to Boston by sea during the summer and upon return suffered from fever and general malaise; was seen soon afterwards by Dr. N. P. Barnes, who diagnosed the condition typhoid fever. At Dr. Barnes's request the writer saw the patient on October 8, soon after an intestinal hemorrhage. The case was one of typical typhoid fever with mental hebetude. The nervous system, however, showed no marked signs of involvement.

Present Illness.—On December 18 was able to leave the house, at which time, however, suffered some pain and stiffness in the lumbar region; was unable to stoop without a good deal of effort. The pains gradually became more severe, radiating down the thighs, and became much aggravated on standing or walking; comfort much greater while in a reclining posture. Bowels regular; sleeps poorly.

February 3.—I saw the patient on this day for the first time since his recovery from the fever. He stands with hands on hips, apparently attempting to support the trunk. Nutrition fair; temperature normal; complains of pain and stiffness in lumbar region; spine appears straight; perceptible rigidity of muscles along the lumbar vertebræ.

February 12.—Patient found attempting to get around on crutches. Pain seems relieved while resting on them. Still complains of inability to sleep.

February 14.—In bed; unable to allow the approach of any one without painful twitchings of thigh muscles; is physically unable to leave the bed; emotionally depressed, with tendency to lacrymation. Rigidity of muscles along lumbar spine easily elicited.

March 8.—General condition has not improved; twitching of muscles still continues. Said he had a chill during the night followed by a feeling of warmth; temperature 101°; there had been no fever until this date. Tenderness and rigidity developed over the left inguinal region; unable to turn in bed without assistance; a surgical consultant considered the possibility of pus formation.

March 11.—Removed to the University Hospital; temperature 101°. Blood count, 4,420,000 red cells; hemoglobin, 70 per cent.; white cells, 8,800. Left thigh perceptibly swollen; tenderness extends downward from Poupart's ligament; when necessary to turn patient in bed cries out with pain; spine absolutely rigid.

March 19.—Left thigh still swollen and painful; unable to move in bed without assistance; cries out in apprehension when approached; temperature, 100°; tendency to insomnia still prevails.

April 28.—Improvement has been gradual to this date, when he was able to leave hospital; pain and rigidity along spinal muscles considerably abated; left thigh and leg perceptibly swollen; sleeps well; appetite good.

May 4.—Thigh somewhat swollen; spinal stiffness but slight.

July 1.—Able to return to work on this date. Has gained considerably in weight.

Treatment.—The nervous manifestations were treated symptomatically. Bromides, valerianates, and somnifacients as trional were given as indicated. The thermocautery was used frequently along the spinal muscles and seemed to ameliorate the pain considerably. Immobilization and support were afforded by means of adhesive plaster strapping, which for his comfort was continued during convalescence. The left thigh was kept elevated as much as possible and treated at first by hot fomentations, later an elastic stocking was advised. Tonics, as iron, quinine, and strychnine, were given after the abatement of the acute symptoms.

*Conclusions.*—(1) The chill, fever, tenderness over the inguinal region, followed by swelling of the thigh undoubtedly represented a thrombophlebitis of the femoral vein.

(2) The absence of elevation of temperature until the thrombus formation is worthy of note, for in the majority of case reports, fever is an early symptom.

(3) Undoubtedly in certain cases of typhoid spine there exists an actual involvement of the nervous system. The cases reported with a persistent Kernig's symptom are rather significant and certainly it would be hard to attribute the marked signs of nervous involvement in my case solely to the psychic effect of the intense pain.

(4) The standing with hands on hips to support trunk, together with the relief obtained while resting on crutches, assisted materially in the diagnosis of spinal involvement.

(5) The term perispondylitis, as suggested by Gibney, perhaps expresses the pathological condition accurately in a majority of cases. Actual involvement of the bone, although occurring, must indeed be rare, owing to the infrequency of case reports of pus formation, but the very fact of the presence of such reports would cause the term to be rejected. Typhoid spine is the best general term we have at our disposal for the condition.

I wish to express my thanks for the courtesy extended to me in this case by Dr. N. P. Barnes of this city and my indebtedness for numerous other opportunities he has afforded me for case study.

## BACILLUS LACTIS BULGARICUS IN INFANTILE GASTROENTERITIS.

By LOUIS H. SCHWARTZ, M.D.,

NEW YORK.

The remarkable results obtained by Clock* in the vomiting and diarrheas of babies by the administration of the *Bacillus lactis bulgaricus* in tablet form led me to try the treatment in a series of cases that came under my care during the months of July and August of the present year. There were fifty-five cases in all. The home conditions of these infants were for the most part wretched, as over ninety per cent. of the parents were very poor, ignorant and superstitious. The cases varied in severity from moderate degrees of infection—six stools a day, to the most grave—twenty and more passages in twenty-four hours. In a few of the babies the stools were blood-stained at the time treatment was begun. The diarrheas had been present anywhere from one day up to a month or more. From three to ten lactic bacillary tablets a day were given to each baby, depending on the gravity of the illness.

Of the fifty-five cases treated, sixteen were breast babies, thirty-two bottle, and seven breast and bottle. The babies ranged in age from a few weeks up to two years; twenty-two were under six months; twenty-five, between six and twelve; and eight between twelve and twenty-four months. Forty-seven were in the first year of life. In thirty-three children there was diarrhea but no vomiting; in twenty there were both vomiting and diarrhea; and vomiting was present alone in two cases. The stools were generally green, watery or curdy, foul, slimy and in a few blood-stained. A temperature over 99° F. was present in twenty cases. Some had a fever as high as 105° F. Some of the patients received no treatment other than the tablets; no starvation, no purgation and no other medication. Seventeen cases received an initial purge of calomel and castor oil and were kept on barley water alone for twenty-four hours or less. As a matter of fact, very few of the mothers of these infants actually kept the babies off milk even for this short period of time. Saline irrigations were used in twenty-seven of the fifty-five cases and bismuth in small doses was administered along with the tablets in thirteen cases. The reason for this will be given further on.

The results obtained were as follows: Forty-three of the children gained in weight outright; two lost; three gained and then later lost, and in seven there was no change of weight recorded. Of the forty-three whose weight increased, twenty-three started with a loss. The babies were weighed once each week, whenever possible. There were no deaths. In all cases, the temperature came down to the normal within one to three days, except in a few, where there was an associated condition such as a bronchopneumonia. Within two or three days after the tablets were used, the stools became yellowish or brown, well-formed, free from curds, mucus, and blood. The number of stools sometimes decreased and sometimes remained unchanged. To the latter children, bismuth subnitrate in tablet form was given in addition to the lactic bacillary tablets with very marked decrease in the frequency of the passages. The tablets seemed to have but slight influence on the vomiting.

While it is not advisable to draw broad general conclusions from so small a number of cases, treated as these were under very trying and unsatisfactory conditions, nevertheless it seems that the administration of the *Bacillus lactic bulgaricus* is a distinct advance in the therapeutics of gastro-enteritis of infants.

## Medicolegal Notes.

**Care and Skill Required.**—In an action for malpractice in resetting the plaintiff's shoulder it was held that if, in performing an operation, a surgeon fails to exercise "a reasonable degree of care and skill" as required by the Georgia Code, he will be liable for any damage which may ensue, without reference to whether he did not possess the requisite amount of skill, or whether he negligently failed to exercise skill which he did possess. The evidence in the case was conflicting, but the evidence for the plaintiff supported her contention that she sustained damage by reason of the unskillful manner in which her dislocated shoulder was reset by the defendant, although a finding would have been authorized that the shoulder was properly set, and the plaintiff's injury was the result of a redislocation brought about by causes over which the defendant had no control. Judgment for the plaintiff was affirmed.—Hinkle v. Smith, Georgia Court of Appeals, 77 S. E. 650.

**Recovery for Services—Evidence of Qualification.**—In an action in the State of New Jersey to recover for the services of a physician rendered in the State of New York, it was held that the facts that (1) the plaintiff had not introduced in evidence his license as a physician and surgeon in the city of New York; and (2) that he had not deposited with the county clerk a copy of any diploma of a legally chartered medical college or university in good standing, or some medical society having power by law to grant diplomas, were not ground for non-suiting the plaintiff.—Corcia v. Guiliano, New Jersey Court of Errors and Appeals, 87 Atl. 94.

**Duty to Reduce Damages by Submitting to Operation.**—When one who has been injured, but is advised by competent physicians that the injury can be remedied by an operation that is ordinarily not dangerous, but refuses to submit to the operation, he is not minimizing his damages, and cannot recover for the sufferings which would be avoided by the needed operation. It is incumbent upon the injured person to submit to reasonable treatment, and to follow the advice of competent physicians.—Donovan v. New Orleans Ry. & Light Co., Louisiana Supreme Court, 61 So. 216.

## THE EPIDEMIOLOGY OF ACUTE ANTERIOR POLIOMYELITIS.

THE noteworthy prevalence of acute anterior poliomyelitis in recent years has afforded opportunities for investigation, of which ample advantage has been taken, and with results that surely are bringing us constantly closer to the solution of an important problem. While the ultimate excitant of the disease has not been definitely isolated to the point of ocular demonstration, it has been shown to consist in a filterable virus susceptible of pathogenic transmission from man to animals and from one animal to another. Also, much has been learned with respect to the modes of conveyance of the causative agent, and something has been accomplished in the direction of prophylaxis and treatment, while we may with confidence look to the near future to unfold a specific therapeusis.

Elaborate studies of all phases of the subject have been made in different parts of the world—and in these our own country has taken no small part—and we may expect before long a clearing up of a number of points still involved in doubt. An admirable piece of work in this connection has been done by Dr. Wade H. Frost, the results of which are contained in Bulletin No. 90 of the Hygienic Laboratory of the United States Public Health Service, recently published. Dr. Frost's observations cover a period of three consecutive years, 1910-1912, and they deal with 799 cases, of which 496 were studied personally.

On the basis of this investigation Dr. Frost expresses the opinion that poliomyelitis is due to a specific infective agent, of which the only demonstrated natural sources are infected human beings, including the obviously sick, convalescents, unrecognized cases, and passive carriers apparently in good health. The infective agent, it has been shown, is contained in the discharges from the respiratory and digestive tracts, is fairly resistant to the destructive agencies encountered in nature outside of the human body, and is capable of gaining access to the tissues of monkeys, and causing infection, through the apparently uninjured nasal mucous membrane; also, though less constantly, through the digestive tract and through the agency of certain biting insects of wide distribution in nature.

The disease is of widespread though infrequent sporadic or endemic occurrence. Within recent years epidemics have occurred throughout a large part of the world, the outbreaks in some instances being circumscribed, while in others they have spread rapidly though irregularly over wide areas. Such epidemics characteristically run a rather rapid course in a given community, declining after a few months or less, after having attacked, so far as is evident, only a small proportion of the total population, usually not more than one in a thousand; and they do not recur in the same locality for a period of not less than two years. In epidemic foci children under the age of five years are attacked much more commonly than are older persons, the entire adult population virtually escaping in some epidemics. These facts can be explained only on the hypothesis that during epidemics the infective agent is widespread, reaching a large proportion of the population, but only occasionally finding a susceptible individual, usually a young person, in whom it gives rise to characteristic morbid effects.

The conclusion that susceptibility to poliomyelitis is comparatively rare and that the incidence of the disease is limited chiefly by a general immunity rather than by the dissemination of the virus explains better than any other hypothesis the epidemiologic peculiarities of the disease, and it is strengthened by the demonstration of the virus in the secretions of well persons. If, in addition, passive carriers are shown to be actually more numerous than clinically recognizable cases of poliomyelitis, then it will be obvious that immunity to the disease is more general than susceptibility.

The only definite conclusion to be drawn from epidemiologic studies is that the infective agent is, during epidemics at least, quite widespread throughout the population affected, the incidence of the clinically recognizable disease being limited by the relatively rare susceptibility to the infection, whatever the route and sources of infection. With respect to susceptibility, age is obviously a factor of importance, susceptibility being generally greatest in the first five years of life, and thereafter progressively diminishing, until in adult life there is a general immunity to natural infection. While this circumstance may be due to a non-specific resistance, developing naturally with maturity, apart from previous exposure to, or infection with, the specific virus of poliomyelitis, a number of facts suggest that the general immunity of adults is specific and developed as the result of previous unrecognized infection. For example, many cases of poliomyelitis occur without the development of paralysis and thus may escape recognition. In the next place, the perennial occurrence of sporadic cases is evidence of the endemicity of the infection. Further, the spontaneous decline of epidemics has been observed in certain localities where only a small percentage of the population has been attacked, with subsequent immunity in such localities, while the epidemic spreads in contiguous localities. The immunity of adults appears relatively greater in large, thickly populated cities than in smaller towns, and especially greater than in rather remote and sparsely populated rural sections. Also, in rural districts the total incidence of epidemic poliomyelitis is higher than in large cities.

## DYSPNEA AND CYANOSIS.

THERE are many sufferers from cardiac and renal disease who at one time or another are troubled with dyspnea. On observation these patients separate themselves readily into two classes, those in whom the dyspnea is accompanied by cyanosis and those who, although suffering extreme distress even while quietly at rest in bed, exhibit no cyanosis. This observation has been made before but until recently there has been no attempt to determine its significance. Thomas Lewis has recently published (*Brit. Med. Jour.*, Nov. 29, 1913; *Heart*, 1913, V, 45) the results of some investigations which he has made with the help of several collaborators. Dyspnea may result from stimulation of the respiratory center by an increase in the $CO_2$ content of the blood. Such dyspnea is practically always accompanied by more or less cyanosis. Dyspnea following exertion is due at first to $CO_2$ concentration but is maintained for long after the blood is properly oxygenated, by the presence in the blood of an excessive amount of lactic acid. Working along this line in cases of so-called cardiac or renal asthma, where cyanosis was absent, they were able uniformly to find "a diminished alkalinity of the blood." It is claimed that "any increase in the acidity of the blood increases the depth and rate of respiration and the connection between these observations is obviously very close." Of course the keystone of the whole work is the method used for the determination of the reaction of the blood. This is based upon the contention that any increase in its acidity means a decrease in the affinity of the corpuscles for oxygen while an increase in the alkalinity means an increased affinity for oxygen. Specimens of blood were exposed to oxygen for a definite length of time and under fixed conditions and their oxygen content determined. These figures were then corrected for the varying hemoglobin content of the specimens examined. Lewis is inclined to believe that dyspnea without cyanosis is due to a condition of acid intoxication and not to the presence of carbon dioxide or alpha oxyacid radicals. It occurs usually in elderly subjects who have lesions in the heart, arteries, and kidneys in varying degrees. He claims that there is no essential difference between cardiac and renal asthma, so-called; and that the dyspnea of the cardiac cases is in reality due ultimately to renal defects.

If it can be properly substantiated this work is really of great importance. It supports Martin Fisher's contention that renal defects are constantly accompanied by an increase in the acidity of the kidney and makes more rational the alkaline treatment which Fisher proposed. If an acid intoxication is the cause of the dyspnea of cardiorenal disease, why may it not be an important factor in the production of uremia as it certainly is in the terminal stages of diabetes? The "vivi-diffusion" experiments of Abel and his co-workers might possibly be used in such an investigation though no attempt has yet been reported to adapt them to the study of disease in man. It is certainly desirable that the investigation be pushed vigorously for chronic nephritis is very largely an unknown territory.

## MODERN ASPECTS OF MENINGOCOCCUS MENINGITIS.

THERE is probably no other disease that more strikingly illustrates the happy results following the cooperation of clinical observation and laboratory research than does epidemic cerebrospinal meningitis. According to Levy, "in no disease are we presented with such favorable conditions for the study of the action of a therapeutic agent on the causative organism and the local inflammatory changes produced by it as in meningococcus meningitis. The treatment takes place under ideal experimental conditions." This quotation is cited in a monograph which has been written by Heiman and Feldstein* of New York. The recent epidemics that prevailed in this city, and the hopes aroused by the introduction of a specific serum in its treatment, have stimulated the study of the many phases of meningococcus meningitis and developed a precision in its management and a special technique in the administration of the curative serum. The chronological arrangement of the bibliographical references indicates clearly the historical advances that have been made in the study of every phase of meningococcus meningitis.

As regards the epidemiology of this disease, the authors point out the irregularity of its progression and diffusion in any given community and the absence of any definite cycle in its recurrence. The relation of healthy carriers to the mode of dissemination of the disease has been carefully studied. Flügge estimated that the number of carriers is ten to twenty times as great as the number of meningitis cases developing during the same period, but recent observations have shown that there are no carriers when no epidemic prevails, or among those who are not exposed to infection. As regards the mode of transmission of the disease there is considerable evidence in support of the view that the infection is carried by droplets from the respiratory tract of infected individuals. Though it has been suggested that the nasopharynx is the portal of entry of this infection, there is no experimental evidence to support this view. Heiman and Feldstein review the data which, although not conclusive, indicate that in meningococcus meningitis there is a primary invasion of the blood and a secondary invasion of the meninges.

The occurrence of meningococcus meningitis in young infants is not as rare as was at one time supposed. Hyperesthesia, rigidity of the neck, and bulging anterior fontanelle are the three most important symptoms of the fully developed disease at this period of life. The Macewen sign is of value only after the anterior fontanelle is closed, while the Kernig and Babinsky signs are of scant diagnostic value in infants under two years of age. The posterior basic meningitis of infants is now established as a definite type of meningococcus meningitis. Pronounced retraction of the head and progressive emaciation are two of the most prominent symptoms.

*"Meningococcus Meningitis," by Henry Heiman, M.D., and Samuel Feldstein, M.D. With introduction by Henry Koplik, M.D. Philadelphia and London: J. B. Lippincott Company, 1913.

Within recent years considerable attention has been paid to the disturbances of respiratory rhythm in meningitis. The irregularities which Conner and Stillman have noted in 95 per cent. of the cases are not as marked in the meningococcus as in the tuberculous variety. There are three kinds of disturbed respiratory rhythm in meningitis, namely, the Cheyne-Stokes, the Biot, and the undulatory types. The frequent deep sighing respirations are regarded as the most striking feature of the Biot type which is observed more frequently in the adult than in the child.

Little difficulty need arise in the diagnosis. The most important symptoms are hyperesthesia, bulging fontanelle in infancy or the Macewen sign in older children and adults, mydriasis on attempted flexion of the head or irritation of the skin, rigidity of the neck, retraction of the head, and the Kernig and Brudzinski signs. Tuberculous meningitis is differentiated chiefly by its slow and insidious onset, by the frequency of photophobia, by the slower and more irregular pulse, by the transitory palsies of the cranial nerves, by the rarity of herpes, and by the less pronounced degree of rigidity of the neck. The other types of meningitis cannot be differentiated in their early stages without the aid of lumbar puncture.

## THE THERMIC TREATMENT OF CANCER.

THERE appears to be a consensus of opinion that cancer is increasing in civilized countries. The statistics quoted by Mr. Frederick L. Hoffmann in his paper read before the recent meeting of the Clinical Congress of Surgeons of North America afford sufficiently conclusive evidence that cancer has increased and is increasing in this country. Indeed, evidence gathered from most countries goes to show that cancer is really increasing. According to the report of the Minister of the Interior of France just issued the cancer death rate in that country shows an increase of 12½ per cent. in five years. This being the situation it is not surprising that the general public as well as the medical profession take an intense interest in any measures suggested as likely to be of a curative and remedial nature. De Keating-Hart of Paris has a paper in the November number of the *Practitioner* on the rational treatment of cancer. Referring to the treatment of what he terms curable cancer he says: "Within the past few years *x*-rays and radium have revolutionized the treatment of cancer condemned as inoperable, and the application of fulguration after an extensive operation has given most gratifying results. Curable cancer may be divided into operable and inoperable. When practicable, an operable cancer should be removed. To submit a growth to the action of the *x*-rays, necessitating a protracted period of therapeutic treatment, involves a great risk of autoinfection; whereas, by excision of the growth and the competent application of fulguration, the patient is given an increased chance of recovery which should not be ignored."

Commenting upon the treatment of inoperable cancer, De Keating-Hart points out that it is not necessarily incurable, as the many successes due to *x*-rays and radium indicate. However, the action of radium is limited, the effective area of Röntgen rays is more extensive, but to secure complete destruction of the tumor, the rays must traverse healthy tissue in such massive doses as seriously to injure its vitality. To counteract this defect of radiation, thermoradiotherapy must be brought into use. The author draws attention to the fact that the radiosensibility of living tissues is governed by a law which is, other things being equal, that the radiosensibility of living cells depends upon their temperature; in other words living cells are more sensitive to destructive agents in general and to *x*-rays in particular, when influenced by heat than when their temperature is low. Thus by heating the tumor itself and by cooling the skin, better results can be obtained than by the ordinary method of Röntgen therapy. De Keating-Hart's conclusions are as follows: (1) In the absence of a general specific treatment for cancer, surgery may cure before the period of general infection. (2) Failure in operation will be very rare if associated with sparking, even after a limited excision. (3) Thermoradiotherapy, association of heat with radiations, will intensify the deep therapeutic value of *x*-rays and of radium in the treatment of many inoperable tumors.

## THE PSYCHOLOGICAL ASPECT OF ATMOSPHERIC SMOKE POLLUTION

THE Mellon Institute of Industrial Research in Pittsburgh has recently instituted investigations into the matter of smoke pollution. There has been established at this institute a smoke investigation staff. One of the staff, Dr. I. E. Wallace Wallin, Director of the Psychological Clinic at the University of Pittsburgh, has published recently a small book dealing with the problem of atmospheric smoke pollution in which he discusses the question mainly from the psychological standpoint. Referring to the mental effects of smoke and smoke-produced weather states Wallin notes that these effects are both direct and indirect. The indirect effects issue from bodily changes produced by smoke or smoke-produced weather states, while the direct effects are due to the influences of the mind's own states upon its subsequent thoughts, disposition, and conduct. He points out that dark clouds have a depressing, devitalizing effect. They may cause fear in children, reduce working efficiency and labor returns, produce eye strain, give rise to disquietude, restlessness, and forboding in the insane, and increase drunkenness. The author concludes by recommending that our knowledge of the mental influence of atmospheric smoke pollution should be rendered more complete by systematic psychological research and indicates the lines upon which such research should be conducted. He brings forward strong arguments in support of the introduction of concerted efforts to control or at least to allay the smoke nuisance. A great deal can be accomplished by arousing public sentiment against the continuance of an evil which after all should not be difficult to abolish or remedy. On esthetic grounds alone there exists sufficient cause for a strong demonstration against the presence of smoke in considerable quantities in the atmosphere and this is one of the least of the objections to smoke.

### Noma.

Noma was a favorite subject for theses in the eighteenth and early nineteenth centuries. Some of it was attributed to abuse of mercurials by yearly reporters. This element, however, could be excluded as a general cause, although the gangrene begins as a stomatitis in certain cases. In modern times the occasional occurrence of a typical noma has led investigators to study the bacteriology of the disease, and the chief conclusion thus far reached is that the affection is due to the parasitism of a spirochete, associated perhaps with other germs, the Vincent couple—spirochete and streptothrix. At a recent session of a Frankfort medical society, Seltz described a case of typical noma. The patient at first developed an ulcerous stomatitis which lasted for six weeks. An ulcer then appeared at the internal angle of the mouth upon the buccal mucosa, and spread rapidly over the right cheek as far as the eyelid. The whole process represented diffuse gangrene, and excision of necrotic tissues could not arrest it. The gangrene progressed, and, together with a putrid bronchitis, carried off the patient. The author believes that the condition originated in the parasitism of Vincent's bacillus along with that of other germs concerning which we know but little.

## News of the Week.

**City Death Rate.**—For the week ending January 10, the death rate in New York City was 14.50 per thousand, the total number of deaths being 1,557. For the same period of last year the rate was 14.68, and the total number of deaths 1,512.

**Harvey Lecture.**—As announced last week, Prof. Sven G. Hedin of the University of Upsala, Sweden, will lecture before the Harvey Society on the evening of January 24, at the New York Academy of Medicine, on "Colloidal Reactions and their Relations to Biology."

**New Hospital Pavilion.**—The new Private Patients' Pavilion of the Flower Hospital at 450 East 54th Street, New York, was opened for inspection on January 17. The building, which is connected with the main hospital by corridors, is six stories high, 140 feet long, and 40 feet wide. The basement contains the main and diet kitchens, dining rooms for the staff, store rooms, etc. On the second floor are the offices and administration rooms; on the second floor semi-private wards containing four to six beds each; on the third floor the maternity ward and private rooms; on the fourth and fifth floors private rooms only; and on the sixth floor the operating rooms. The building is supposed to be fireproof and there is no wood trim in it.

**Alumni Meeting.**—The annual meeting of the Association of the Alumni of the College of Physicians and Surgeons, New York, will be held at the College on the evening of Monday, January 26. The executive session will be called to order at eight-fifteen, and will be followed by the scientific session, which will be under the auspices of the Department of Anatomy of the College.

**Surgeon-General Gorgas.**—On January 17, President Wilson nominated Col. William C. Gorgas to succeed the late General Torney as Surgeon-General of the United States Army. Colonel Gorgas has been an officer in the Army Medical Corps since 1885, and reached the grade of colonel last March. The present appointment is intended as a recognition of the wonderful work which he did in the sanitation of the Panama Canal Zone. At present he is in South Africa acting as a consultant for the British Government in arranging a system for the improvement of sanitary conditions in the diamond mine regions.

**Dr. Biggs for State Commissioner.**—Governor Glynn of New York announced on January 15 his intention to send to the Senate his nomination of Dr. Hermann M. Biggs to be State Commissioner of Health, for a term of five years. Dr. Biggs, who recently resigned as General Medical Officer of the New York City Department of Health, has had a long and wide experience in public health matters, and the State is to be congratulated on his willingness to take up the arduous duties of the State Department. In naming him, Governor Glynn said: "Not a single political recommendation was made in the case of Dr. Biggs. Every request made for his appointment came from some big uplift organization or some prominent man who saw in his selection the establishment of great things in public health work. I believe I have obtained the services of the best man in the country for the administration of the new health laws."

**Health Commissioner Goldwater.**—Mayor Mitchel has appointed Dr. S. S. Goldwater, Superintendent of Mt. Sinai Hospital, Health Commissioner of New York City. Dr. Goldwater was graduated from the University and Bellevue Hospital Medical School in 1901. In 1908 he was appointed an adviser in matters of hospital construction to Bellevue, Harlem, Fordham, and Gouverneur hospitals, and has served also as an adviser to private hospitals, including the Presbyterian and New York hospitals, the Montefiore Home and many institutions in other parts of the country. He is vice-president of the New York Academy of Medicine and is secretary of the Associated Out-Patient Clinics of the City of New York. In 1908 he was president of the American Hospital Association.

**School to Name Hospital Men.**—By an arrangement between the University of Louisville and the City Hospital, the Board of Trustees of the University will hereafter have the sole power of appointment of the medical and surgical staffs of the hospital.

**Centenarian Dead.**—At the reputed age of 110 years Mrs. Nora Sullivan of Potsdam, N. Y., died on January 16. She came to this country from Ireland seventy-five years ago, and for eighty years had been an habitual user of tobacco.

**Preventive Vaccination in Philadelphia.**—A pupil in the Drexel Institute, Philadelphia, returning from a visit to his mother who subsequently developed smallpox, was removed from the school to the Municipal Hospital for Contagious Diseases for observation, and the house in which he roomed and that in which he took his meals were temporarily quarantined. All the lodgers and boarders in the two houses were vaccinated as well as fifty pupils in the Institute and the president and members of the Faculty.

**City Workers' Welfare.**—Commissioner Lederle of the New York City Department of Health has recently formed an organization for welfare work among the employees of the department. It is planned to include the following activities: Investigation of all absences over forty-eight hours;

the keeping of records of the physical condition of the employees; the provision and supervision of a suitable retiring room for women and of a suitable lunch room; the establishment of an open air roof garden for the use of employees during the lunch hour; the organization of a vacation camp for women; and the delivery of lectures on personal hygiene. The Commissioner believes that the efficiency of the department and its employees can be greatly increased by the adoption of such a system.

**Saturday and Sunday Association.**—After an investigation of several months, the Hospital Saturday and Sunday Association of New York at a recent meeting decided to reform its methods of aiding certain hospitals. Heretofore cash has been distributed among those hospitals which announced that they would receive charity cases, but there has been no exact determination of the value of each hospital's services to charity. Hereafter account will be taken of the cost of all free treatments and an allowance of three dollars a day for surgical cases but only seventy-five cents a day for convalescents and incurables will be made. The association will also strike from its roll of beneficiaries all hospitals marked "Grade C" by the State Board of Charity; such institutions will receive this year only 50 per cent. of their former allowance, and next year will be dropped entirely. It was also decided that hereafter no hospital shall be admitted to membership unless it has a minimum of thirty-five beds and has given at least 5,000 days of free treatment a year for three years preceding the date of its admission.

**Bad Hospital Conditions.**—The building of a new hospital for children on Blackwell's Island, the abandonment of the present Infant's Hospital on Randall's Island, and sweeping reforms in the treatment of children throughout the city's whole municipal hospital system, were urged in a report submitted recently to the Board of Estimate by the Hospital Investigating Committee. The report charges that children in the city hospitals are often infected with diseases which they did not have when they were admitted, that surgical cases are not properly cared for and poisoning often develops, and that the cases are not properly classified. The report recommends the employment of resident children's specialists in the city hospitals and the organization of a children's nursing staff under the direction of a specially trained nurse. For the new hospital a site on Blackwell's Island just south of the City Home is selected as desirable, and it is recommended that the new hospital be planned to accommodate ultimately 1,000 children. In the same report a charge of careless treatment of the patients in the Out-Patient Department of Gouverneur Hospital is made, the bad conditions being blamed partly to the present cramped quarters.

**Medical Society Elections.**—AMERICAN COLLEGE OF SURGEONS.—At a meeting of the Board of Regents of the American College of Surgeon, held in New York on January 9, the following officers were elected: *President*, Dr. J. M. T. Finney, Maryland; *First Vice-President*, Dr. W. W. Chipman, Quebec; *Second Vice-President*, Dr. Rudolph Matas, Louisiana; *Treasurer*, Dr. Albert J. Ochsner, Illinois; *General Secretary*, Dr. Franklin H. Martin; *Members of the Board of Regents*, J. M. T. Finney, Maryland; Albert J. Ochsner, Illinois; Franklin H. Martin, Illinois; George E. Brewer, New York; George E. Armstrong, Quebec; John B. Murphy, Illinois; Edward Martin, Pennsylvania; Frederic J. Cotton, Massachusetts; Herbert A. Bruce, Ontario; Charles F. Stokes, Washington, D. C.; William D. Haggard, Tennessee; George W. Crile, Ohio; Robert E. McKechnie, British Columbia; Charles H. Mayo, Minnesota, and Harry M. Sherman, California.

EMMET COUNTY (MICH.) MEDICAL SOCIETY: Annual meeting at Petoskey on December 11. Officers elected: *President*, Dr. L. W. Gardner; *Vice-President*, Dr. L. S. Crotser; *Secretary-Treasurer*, Dr. G. W. Nihart.

NEWTON-NESHOBA-WINSTON TRI-COUNTY (MISS.) MEDICAL SOCIETY: Annual meeting at Newton on December 9. Officers elected: *President*, Dr. J. J. Rush, Philadelphia; *Vice-Presidents*, Dr. G. H. McNeill, Newton, and Dr. T. M. Crosby, Neshoba; *Secretary-Treasurer*, Dr. S. A. Majure, Dixon.

RANKIN-HINDS COUNTY (MISS.) MEDICAL SOCIETY: Annual meeting at Jackson on December 9. Officers elected: *President*, Dr. R. S. Currie, Jackson; *Vice-Presidents*, Dr. R. B. Price, Bolton, and Dr. C. C. Shotts, Pelahatchee; *Secretary-Treasurer*, Dr. J. H. Fox, Jackson.

KAY COUNTY (OKLA.) MEDICAL SOCIETY: Annual meeting at Blackwell on December 10. Officers elected: *President*, Dr. H. M. Strickland, Tonkawa; *Vice-President*, Dr. W. W. Lemmon, Nardin; *Secretary-Treasurer*, Dr. E. J. Orvis, Blackwell.

CLARK COUNTY (OHIO) MEDICAL SOCIETY: Annual meeting at Springfield on December 8. Officers elected: *President*, Dr. James E. Studebaker; *Vice-President*, Dr. Carl Ultes; *Secretary*, Dr. D Pote; *Treasurer*, Dr. W. C. Taylor.

FALL RIVER (MASS.) MEDICAL SOCIETY: Annual meeting on December 10. Officers elected: *President*, Dr. Milne B. Swift; *Vice-President*, Dr. C. A. Howland; *Secretary*, Dr. R. W. French; *Treasurer*, Dr. D. J. Fennelly.

UNION COUNTY (KY.) MEDICAL SOCIETY: Annual meeting at Morgantown on December 3. Officers elected: *President*, Dr. C. P. Cottingham, Uniontown; *Secretary*, Dr. Henry B. Allen, Morganfield.

FAYETTE COUNTY (KY.) MEDICAL SOCIETY: Annual meeting at Lexington on December 9. Officers elected: *President*, Dr. C. L. Wheeler; *Vice-President*, Dr. L. H. Mulligan; *Secretary-Treasurer*, Dr. L. C. Redmon.

COLBERT COUNTY (ALA.) MEDICAL SOCIETY: Annual meeting at Tuscumbia on December 10. Officers elected: *President*, Dr. W. H. Green; *Vice-President*, Dr. W. A. Finley; *Secretary-Treasurer*, Dr. J. T. Haney.

CHILTON COUNTY (ALA.) MEDICAL SOCIETY: Annual meeting at Mountain Creek on December 3. Officers elected: *President*, Dr. J. P. Hayes; *Secretary*, Dr. T. J. Marcus.

MARICOPA COUNTY (ARIZ.) MEDICAL SOCIETY: Annual meeting at Phoenix on December 6. Officers elected: *President*, Dr. Roy Thomas; *Secretary*, Dr. W. Warner Watkins; *Treasurer*, Dr. E. S. Godfrey, Jr.

FRANKLIN COUNTY (ARK.) MEDICAL SOCIETY: Annual meeting at Ozark on December 7. Officers elected: *President*, Dr. T. B. Blakely, Coal Hill; *Vice-President*, Dr. E. D. Warren, Ozark; *Secretary-Treasurer*, Dr. Thomas Douglass, Ozark.

DES MOINES COUNTY (IA.) MEDICAL SOCIETY: Annual meeting at Burlington on December 10. Officers elected: *President*, Dr. A. C. Moerke; *Vice-*

*President*, Dr. R. F. Karney; *Secretary*, Dr. E. A. Hunt.

Iowa City (Ia.) Medical Society: Annual meeting on December 4. Officers elected: *President*, Dr. C. S. Chase; *Vice-President*, Dr. Mildred Sheetz; *Secretary*, Dr. Z. W. Stewart.

Walker County (Ala.) Medical Society: Annual meeting at Jasper on December 16. Officers elected: *President*, Dr. A. M. Waldrop, Cordova; *Vice-President*, Dr. Orizaba Manasco, Townly; *Secretary-Treasurer*, Dr. James L. Sowell, Jasper.

Peoria (Ill.) City Medical Society: Annual meeting on December 16. Officers elected: *President*, Dr. Sumner M. Miller; *Vice-President*, Dr. Charles D. Thomas and Dr. Jabas F. Cooper; *Secretary*, Dr. Elbert W. Oliver.

Lauderdale County (Miss.) Medical Society: Annual meeting at Meridian on December 13. Officers elected: *President*, Dr. T. D. Bourdeaux; *Vice-President*, Dr. K. T. Klein; *Secretary-Treasurer*, Dr. G. F. Douglass.

Pettis County (Mo.) Medical Society: Annual meeting at Sedalia on December 15. Officers elected: *President*, Dr. W. A. Beckemeyer; *Vice-President*, Dr. Guy Titsworth; *Secretary*, Dr. F. B. Long; *Treasurer*, Dr. W. J. Wills.

Polk County (Mo.) Medical Society: Annual meeting at Morrisville on December 13. Officers elected: *President*, Dr. R. Lee Russell, Bolivar; *Secretary*, Dr. J. F. Roberts, Bolivar.

Yankton District (S. D.) Medical Society: Annual meeting at Yankton on December 15. Officers elected: *President*, Dr. Charles M. Keeling, Springfield; *Vice-President*, Dr. M. Herzberg, Vermilion; *Secretary-Treasurer*, Dr. James Roane, Yankton.

Elmore County (Ala.) Medical Society: Annual meeting at Wetumpka. Officers elected: *President*, Dr. Jesse Gulledge; *Vice-President*, Dr. E. P. Moon, Wetumpka.

Mobile County (Ala.) Medical Society: Annual meeting at Mobile on December 13. Officers elected: *President*, Dr. R. A. Wright, Mobile; *Vice-President*, Dr. J. T. Inge; *Secretary*, Dr. W. W. Scales; *Treasurer*, Dr. Angelo Festorazzi.

Iowa County (Ia.) Medical Society: Annual meeting at Davenport on December 11. Officers elected: *President*, Dr. Charles F. Noe, Amana; *Vice-President*, Dr. L. B. Amick, Millersburg; *Secretary*, Dr. George F. Schug, Williamsburg.

Muscatine County (Ia.) Medical Society: Annual meeting at Muscatine on December 30. Officers elected: *President*, Dr. E. K. Tyler; *Vice-President*, Dr. A. R. Leith, Wilton; *Secretary-Treasurer*, Dr. W. H. Johnson, Muscatine.

Rock County (Wis.) Medical Society: Annual meeting at Janesville on December 29. Officers elected: *President*, Dr. J. W. Kiethley, Beloit; *Vice-President*, Dr. Guy C. Waufle, Janesville; *Secretary*, Dr. Fred E. Sutherland, Janesville.

Missoula County (Mont.) Medical Society: Annual meeting at Missoula on December 27. Officers elected: *President*, Dr. S. H. McCall; *Vice-President*, Dr. George F. Turman; *Secretary-Treasurer*, Dr. Allen G. Fuller.

Blue Earth County (Minn.) Medical Society: Annual meeting at Mankato on December 29. Officers elected: *President*, Dr. G. A. Dahl, Mankato; *Vice-President*, Dr. T. G. Clement, Vernon Center; *Secretary*, Dr. R. N. Andrews, Mankato; *Treasurer*, Dr. Lida Osborn, Mankato.

Jackson County (Ill.) Medical Association: Annual meeting at Duquoin on December 26. Officers elected: *President*, Dr. J. W. Barrow, Carbondale; *Vice-President*, Dr. C. E. Riseling, Murphysboro; *Secretary-Treasurer*, Dr. R. B. Essick, Murphysboro.

Orleans Parish (La.) Medical Society: Annual meeting at New Orleans on December 13. Officers elected: *President*, Dr. C. N. Chaviguy; *Vice-Presidents*, Dr. L. R. De Buys, Dr. M. Thomas Lanaux, and Dr. William H. Block; *Secretary*, Dr. E. L. King; *Treasurer*, Dr. George H. Upton.

Greene County (Mo.) Medical Society: Annual meeting at Springfield on December 12. Officers elected: *President*, Dr. G. B. Lemmon; *Vice-President*, Dr. O. C. Horst; *Secretary*, Dr. T. O. Klingner; *Treasurer*, Dr. D. B. Farnsworth.

Monmouth County (N. J.) Medical Society: Annual meeting at Asbury Park on December 16. Officers elected: *President*, Dr. R. S. Bennett, Mayor of Asbury Park; *Vice-President*, Dr. E. M. Beach, West Long Branch; *Secretary*, Dr. L. D. Wise, Long Branch; *Treasurer*, Dr. W. A. Robinson, Ocean Grove.

Columbia (S. C.) Medical Society: Annual meeting at Columbia on December 16. Officers elected: *President*, Dr. F. Asbury Coward; *Vice-President*, Dr. P. V. Mickell; *Secretary-Treasurer*, Dr. Edith Welborn.

McNairy County (Tenn.) Medical Society: Annual meeting at Selmer on December 18. Officers elected: *President*, Dr. E. M. Smith, Bethel Springs; *Vice-President*, Dr. H. C. Sanders, Lawton; *Secretary-Treasurer*, Dr. T. G. Jackson.

Tarrant County (Tex.) Medical Society: Annual meeting at Fort Worth on December 22. Officers elected: *President*, Dr. S. A. Woodward; *Vice-President*, Dr. J. A. Gracey; *Secretary*, Dr. Frank Sanders.

Sheboygan County (Wis.) Medical Society: Annual meeting at Sheboygan on December 19. Officers elected: *President*, Dr. J. A. Junck; *Vice-President*, Dr. J. C. Tasche; *Secretary-Treasurer*, Dr. G. Edmund Knauf.

College of Physicians of Philadelphia.—At a stated meeting on January 7 Dr. Frederick P. Henry read a memorial to the late Dr. Richard Clenmann. The following officers were re-elected for the ensuing year: *President*, Dr. James C. Wilson; *Vice-President*, Dr. Richard H. Harte; *Secretary*, Dr. Thomas R. Neilson; *Treasurer*, Dr. John B. Roberts; *Honorary Librarian*, Dr. Frederick P. Henry.

Nashville (Tenn.) Academy of Medicine: Annual meeting at Nashville on January 6. Officers elected: *President*, Dr. Duncan Eve, Jr.; *Vice-President*, Dr. W. E. Hibbett; *Secretary*, Dr. John F. Gallagher.

San Antonio (Tex.) Academy of Medicine: This institution, the first of its kind in the State, was chartered last December, for the advancement of medical science, research, and investigation.

York County (Me.) Medical Society: Annual meeting at Biddeford on January 7. Officers elected: *President*, Dr. J. W. Gordon, Ogunquit; *Vice-President*, Dr. Joseph M. O'Connor, Biddeford; *Secretary*, Dr. A. L. Jones, Old Orchard; *Treasurer*, Dr. Charles F. Traynor, Biddeford.

**Obituary Notes.**—Dr. Mary J. McCleery of New York, a graduate of the Woman's Medical College of the New York Infirmary for Women and Children in 1877, died suddenly at her home on January 12, aged 70 years.

Dr. Thomas Judson Wright of Norfolk, Va., a graduate of the George Washington University, Department of Medicine, Washington, in 1870, and of the Bellevue Hospital Medical College, New York, in 1871, died at St. Christopher's Hospital, as the result of injuries caused by a fall from his horse two weeks before, on December 15, aged 68 years.

Dr. John G. Cecil of Louisville, Ky., a graduate of the Hospital College of Medicine, Louisville, in 1879, until recently professor of the principles of medicine and of clinical medicine in the University of Louisville, Medical Department, a member of the American Medical Association, the Kentucky State Medical Association, of which he was at one time president, and the Jefferson County Medical Society, died at his home, after a lingering illness, on December 13, aged 58 years.

Dr. Alexander O. Erskine of Memphis, Tenn., a graduate of the New York University Medical College in 1858, a veteran of the Civil War, having served as a surgeon with the Confederate Army, professor of obstetrics and pediatrics in the Memphis Hospital Medical College from 1885 to 1906, and since that time emeritus professor, at one time dean of the college, and from 1902 to 1910 a member of the attending staff of the Memphis City Hospital, and a member of the Tennessee State Medical Association, the Tri-State Medical Society, and the Shelby County Medical Society, died at his home on December 13, aged 81 years.

Dr. Alvaro E. Mossman of Westminster, Mass., a graduate of the Bellevue Hospital Medical College, New York, in 1884, a member of the Massachusetts State and Worcester North District Medical Societies, and pathologist and attending physician to the Henry Heywood Hospital, Gardner, died suddenly at his home, from angina pectoris, on December 19, aged 56 years.

Dr. Jesse Franklin Frisbie of Newton, Mass., a graduate of the Harvard Medical School, Boston, in 1861, assistant surgeon in the United States Navy in 1862 and 1863, and from 1864 to 1865 in charge of the Wisewell Barracks Hospital in Washington, D. C.; a practicing physician in Newton since 1872, formerly a member of the staff of the Newton Hospital and of the Newton Board of Health, and a member of the Massachusetts State and Middlesex South District Medical Societies, died at his home, after a short illness, on December 17, aged 75 years.

Dr. Howard Beck Reed of Sea Bright, N. J., a graduate of the College of Physicians and Surgeons, New York, in 1910, died at the Neurological Institute, New York, on December 27, aged 29 years.

Dr. Juan Domingo Fernandez of Jacksonville, Fla., a graduate of the Medical College of Virginia, Richmond, in 1870, a member of the American Medical Association, the Florida Medical Association, of which he was the secretary-treasurer, and the Duval County Medical Society, and secretary of the Regular Board of Medical Examiners of the State died at his home on December 15, aged 65 years.

Dr. W. S. Woolford of Kingsland, Ark., a graduate of the University of Arkansas, Medical Department, Little Rock, in 1884, a member of the American Medical Association and the Arkansas and Cleveland County Medical Societies, died at his home, after a lingering illness, on December 16.

Dr. Noel M. Darden, formerly of Norwood, Ga., a graduate of the Medical College of Georgia, Augusta, in 1879, died at his home in Atlanta, after a long illness, on December 4, aged 58 years.

Dr. Robert A. Smith of New Castle, Ind., a graduate of the Physio-Medical Institute, Cincinnati, O., in 1870, and a member of the Indiana State and Henry County Medical Societies, died after a short illness, on December 15, aged 67 years.

Dr. Thomas Elwood Parker died at Woodbury, N. J., on December 29, as the result of an attack of apoplexy, at the age of 59 years. He was graduated from Hahnemann Medical College and Hospital in the class of 1889. He was secretary of the local Board of Education and of the Gloucester County Historical Society and Medical Inspector of Schools.

Dr. Michael A. Jordan of Logansport, Ind., a graduate of the Medical College of Ohio, Cincinnati, in 1876, died at the Johns Hopkins Hospital, Baltimore, from cancer of the stomach, on December 13, aged 58 years.

Dr. Felipe Martinez of San Francisco, Cal., a graduate of the National College of Medicine of Mexico in 1870, died at his home, after a brief illness, on December 10, aged 72 years.

Dr. Marshall R. Borst of Glen Elder, Kan., a graduate of the College of Physicians and Surgeons, Keokuk, Ia., in 1888, and a member of the Kansas and Mitchell County Medical Societies, died at his home from paralysis, on December 23, aged 58 years.

Dr. David Steiner of Lima, O., a graduate of the University of Michigan, Department of Medicine and Surgery, Ann Arbor, in 1883, a member of the American Medical Association, the Ohio State Medical Association, and the Allen County Medical Society, having served as vice-president and president, respectively, of the latter, consulting surgeon of the Lima Hospital, and a trustee of the Lima District Tuberculosis Hospital, died at his home from typhoid fever on December 27, aged 57 years.

Dr. Henry Banga of Chicago, Ill., a graduate of the University of Basel, Switzerland, in 1875, professor of gynecology in the Chicago Polyclinic, and a member of the American Medical Association, the Illinois State and Chicago Medical Societies, and the Chicago Gynecological Society, died suddenly, while performing an operation at the home of the patient, on December 24, aged 65 years.

Dr. James A. J. McDonald of Santa Rosa, Cal., a graduate of the College of Physicians and Surgeons, San Francisco, in 1898, died recently in San Fransisco, aged 62 years.

Dr. Adolph E. Linder of East St. Louis, Ill., a graduate of the American Medical College, St. Louis in 1896, died at his home on December 27, aged 43 years.

Dr. Max Dantes of New York, a graduate of the Bellevue Hospital Medical College, New York, in 1893, died at his home, after a long illness on January 8, aged 41 years.

Dr. Niles M. Miller, formerly of Philadelphia, a graduate of the University of Pennsylvania, Department of Medicine, in 1881, died at his home at Avon-by-the-Sea, N. J., on January 6, aged 69 years.

Dr. William J. E. Rush of Allentown, Pa., a graduate of the Medico-Chirurgical College of Philadelphia in 1896, died at his home on January 6, aged 40 years.

Dr. William L. Broaddus of Bowling Green, Va., a graduate of the New York University Medical College in 1868, a member of the Medical Society of Virginia, and a veteran of the Civil War, having served throughout in the Confederate Army, died at his home on January 4, aged 67 years.

## PUBLICITY.

*To the Editor of the* MEDICAL RECORD:

SIR:—The following letter was written a year ago to a newspaper which shall be nameless. It was not published:

"During a recent meeting of the American Association for the Advancement of Science, there appeared on an inner page of a Cleveland newspaper in large capitals the heading, 'Would Sterilize Defectives.' Due perhaps to hurried publication or perhaps to labor union affiliation, the 'f' in defectives was mentally changed to 't' by the person who arranged the table of contents on the first page of the newspaper, so that the heading in this later position read, 'Would sterilize sleuths.' There is much 'newspaper medicine' of this variety. The better sense of the medical profession deprecates newspaper publicity, especially in connection with the announcement of new results, since such publicity tends to raise hopes which are not justified in one case out of a thousand. For example, within a year a newspaper announcement of a foreign 'cure for cancer' led a physician to remark that within twenty-four hours some fake would be reported on this side of the water, and, sure enough, a Brooklyn physician announced the following day that he had been using the same 'cure' for two years with great success. It can be positively stated that, at the present time, no cure for cancer is known. The newspaper announcement of alleged 'cures' may simply cause the reaping of a harvest by the charlatan. Newspaper publicity also often leads to the exploitation of an individual who, however great his work, is certainly hurt in the eyes of the rank and file of laboratory workers who may be acquainted with the fact that greater credit attaches to the work of some man unknown and unknowable to the newspaper office." GRAHAM LUSK.

## OUR LONDON LETTER.

(From Our Regular Correspondent.)

CONGRESSES TO COME—HONORS AT THE NEW YEAR—INSURANCE AND CONTRACT PRACTICE—PANEL AND NON-PANEL—NATIONAL MEDICAL UNION—BRITISH MEDICAL ASSOCIATION'S CONSTITUTION, FINANCES, AND JOURNAL—OBITUARY.

LONDON, January 2, 1914.

THE number of medical congresses for the year 1914 seems larger than ever: including exhibitions and conferences and those on nursing and hygiene I have a list before me of twenty-five of which the dates are announced, twelve of them calling themselves International. Besides these there are about a dozen international ones which will become due in the two following years according to their usual periods of meeting.

The list of honors conferred by the King on the opening of the New Year contains the names of thirteen members of the profession. Sir A. Geikie is given O.M. (Order of Merit); Surgeon-General May is made Hon. Physician to the King; Surgeon-General Sloggett receives knighthood, so do Prof. H. B. Cullen (Melbourne), Dr. T. B. Nariman (Bombay), and Professor Rutherford, Sir Rickman Godlee, and Sir Job Collins are given the K.C.O.V.; William Stafford of the Irish L. G. B. gets a baronetcy, and Sir C. Nixon a P.C. for Ireland; Surgeon-General Hathaway the C.B.; Major Robertson the C.I.E.; Dr. Stokes the Kaisur-Hind medal, as do Dr. Carleton and Rev. J. Shepherd.

We have now had nearly a year's experience of the medical revolution brought about by the Insurance Act and the question whether it has proved a benefit or otherwise is again being discussed by the public. Advocates of committing to the state every kind of service that can be contracted for are numerous and active. They speak of free choice of doctor as a mere fancy and tell you that fourteen millions of people are already on the panel and are as well satisfied and as carefully attended as under the superseded Poor Law Service. There is some truth in this but they forget to add that the older system never gave real satisfaction—a fact which led to the Poor Law Commission on which the advocates of this Fabian policy although in a minority managed to force their views. The great public is as indifferent as usual. It seems always much easier to excite a desire for change than to induce those who are contented to oppose interference. The advocates of complete State Service declare that under it the choice of the doctor is no more restricted than under the Poor Law and the Club system. There is sufficient truth in this statement to make it plausible to those it does not affect and who do not think it out. But those who have witnessed the working of those plans know how misleading it is. The club elected the doctor for the year and every member could vote. The parish doctor was appointed by the guardians and the poor patients had no voice in the matter; they were receiving parish relief, including medical attendance, and of course there was no desire to increase their numbers.

The Insurance Act came as a political scheme to organize the profession on a contract basis and work it on the pattern of the civil service. But such a plan had never succeeded where attempted and the English public would never have consented to give up the free choice of their doctors. The panel system was therefore adopted as a step in the direction and forced on the profession by a socialistic and determined government. Resistance was aroused and proved so powerful that the acute Chancellor of the Exchequer had to raise his price whereupon a stampede to the panel took place and that a not very creditable one, for it included many who had loudly declared they never would consent, seeing which the weaker men followed. The élite of the profession of course held aloof and after a time the non-panel men found it convenient to combine and many local societies were formed. These soon found it necessary to federate, and in November, as I reported to you, a meeting was held at which a committee or council was appointed to organize a plan under the title of the "National Medical Union." Yesterday this body met and issued a statement of the policy they have formulated, viz.: (1) To maintain the freedom of the relations between the profession and the public. (This obviously includes the chief point at issue—free choice of doctor.) (2) To support the public in this and to safeguard national health. (3) To oppose the present arrangements under the acts and decline service under them. The union is to be independent of politics and will not interfere with the British Medical Association. It is in fact to be composed only of non-panel men and devoted entirely to non-panel interests. Every non-panel man is eligibile and is earnestly desired to join.

The managing group of the British Medical Association seem to have little difficulty in effecting their purpose of changing its constitution. The alterations they desired in the memorandum of association which were approved, as I informed you, at the extraordinary meeting early in December were required to be confirmed at a general meeting. An extraordinary general meeting for this purpose was summoned for December 23, on

which date there was not a quorum and the meeting stood adjourned until the 30th. On this date the indifference of members had been sufficiently overcome to bring thirteen together, and of these twelve voted the confirmation of the changes. It may surprise many that their apathy has handed them over to the small ruling clique and already it is being said that the constitution permitting a dozen to determine the interests of thousands is a *reducto ad absurdum*. It will surprise them more to learn that at a meeting under the circumstances of this last no quorum is required and that the presence of one member would have sufficed. It would however be a nice legal point to determine whether the word *meeting* would not demand two persons at least.

It looks as if the constitution had been designed on purpose to enable a few to engineer its proceedings and that has almost always been done. It is true that if the members were determined to take any trouble they might carry some point, but not by a mere resolution at a general meeting, for such a decision has been at times actually disregarded. The effect of the changes now decided on is to extend the powers of the association generally, but a proviso is that it shall not support with funds or endeavor to promote any regulation or condition which would tend to make the association a Trade Union. Another effect enables the council to carry out their project of raising the price of the *Journal* to 2 guineas. They have promptly proceeded to do so and must have prepared in advance the circular demanding remittance of that sum for the decision passed on the 30th ult. and yesterday by the first post of the new year it was delivered to members. It is obvious that any member disapproving the changes to the extent of resigning—and many threats of doing so had been in circulation—had only a single day to do it before becoming liable for the new subscription. The suggestion that such sharp practice is the custom of the council seems harsh though it is likely enough that they reckoned on the usual apathy of members. But I do not suppose they would try to enforce payment on any one who objected under such circumstances. Time will show whether many will actually resign and the promise to devote the increased income to the defence of the profession may avail somewhat. No doubt there will be some resignations for one hears many have taken the step and many more say they will.

The greatest offence seems to be adding to the price of the journal which is declared not worth the price, but above all it is declared to be conducted in the most extravagant manner. It is certainly amazing that with a circulation of so many thousands and an advertising connection of as many thousands a year that a loss should result. Any publisher or printer would be glad to contract for its production and pay handsomely for the privilege of making a good profit for himself.

Dr. Hills Harris who qualified in 1844 at the two Royal Colleges and practised for many years but had long since retired, has died in the ninety-first year of his age.

Dr. Bertram Thornton, M.O.H., and consulting surgeon to the Hospital, Margate, has died there in his fifty-seventh year. He held a number of other offices in the town, among them surgeon to the police, medical officer for the borough schools, and for the post office.

Mr. W. Booth Pearsall, F.R.C.S.I., was for many years leading dental surgeon in Dublin and the founder of the Dental Hospital of Ireland. He qualified at the Dublin Royal College of Surgeons in 1866 and devoted himself to dental surgery. He was elected a Fellow of the College in 1875 and appointed to a lectureship there. He was the organizer and honorary secretary of the first meeting of the British Dental Association in Ireland in 1888.

## OUR PARIS LETTER.

(From Our Regular Correspondent.)

CONGRESS OF FRENCH PEDIATRISTS—OBESITY IN CHILDHOOD — FRÖHLICH'S SYNDROME — FRENCH SURGICAL ASSOCIATION—THE OPEN TREATMENT OF ANKYLOSES—OBITUARIES: PONCET, TENNESON.

PARIS, December 1, 1913.

THE Congress of French Pediatrists was held in Paris from the third to the seventh of October under the presidency of M. Nette. Obesity in childhood was the first subject under discussion. Le Gendre in his paper assigned an important place in this condition to heredity. Most of the children belong to families that have been addicted for generations to overfeeding. The important exciting factors are insufficiency of the vascular glands, endogenous intoxications, and certain exogenous poisons as alcohol and lead. Among the symptoms may be noted the absence of cardiac troubles which are rather common in adults. The prognosis is not grave. The chances are that many of these children will reach adult life and will become more obese. Some of them will lose their fat with the development of the genital organs at puberty. The treatment is the same as in the adult. In pronounced cases passive muscular exercises, produced by the electrical method devised by Bergonié, are of great value. In almost all cases the treatment is rendered difficult by the fact that the children eat an excessive amount of food.

G. Mouriquand of Lyons devoted his attention to the study of the syndrome adiposo-genitalis. In 1901 Fröhlich described the following triad of symptoms as constituting this syndrome: a lesion of the hypophysis, almost always neoplastic; marked obesity; and atrophy or retarded development of the genital organs. Sometimes the hypophysis is involved only indirectly. This occurs in certain cases of hydrocephalus. Experimentally ablation of the hypophysis has resulted in the production of this syndrome. There is in these cases an increased tolerance for carbohydrates. From the viewpoint of therapeutics surgery has given some relief in cases of tumor of the hypophysis. The *x*-rays have been of some value, and the administration of hypophysis extract alone has been of less value than when this is combined with testicular and thyroid extracts.

In the discussion M. Geimon alluded to the frequent association of obesity and tuberculosis. M. Hallé also noted this coexistence, and pointed out the danger of the thyroid treatment in obese children affected with tuberculosis. Léopold Lévy has not observed any good results following the use of thyroid extract in these cases, except in the case of girls from 16 to 20 years of age.

The seventy-sixth annual congress of the French Surgical Association convened at Paris, October 6. under the presidency of Professor Kumisson. A. Baumgartner discussed the subject of the open treatment of ankyloses. He noted that the surgical measures consisted in resections, the interposition

of foreign bodies, the interposition of soft parts attached to a pedicle, the simple transplantation of tissues, and articular grafts. Simple resection has given good results at the knee, at the elbow, and at the wrist, and, best of all, at the shoulder and hip. The use of foreign bodies has generally been abandoned. Living flaps, particularly if consisting of adipose tissue, aponeurotic membrane, peritoneum, hernial sac, etc., is of value particularly in adults. Articular grafts may be total or partial. The grafting of entire joints was demonstrated as feasible in experiments performed on animals by Judet and was practised on human beings by Lexer, Kuttner, and others. The authors gave preference to the procedure of interposing muscle tissue between the joint surfaces. The mental attitude of the patient must be considered. The patient must cooperate in every way with the surgeon. It is important to extirpate every vestige of the morbid tissue that has produced the ankylosis. Denucé of Bordeaux described the surgical procedures applicable in the treatment of particular ankyloses.

Professor Poncet who died recently at the age of 57 years was one of the distinguished figures of the Lyons school. He finished at Paris the studies that he began at Lyons in the service of Ollier. Agregé in Paris in 1879, he returned to Lyons where he was appointed professor of operative surgery in 1882. In 1890 he became professor of clinical surgery. At first his attention was devoted exclusively to surgery; later his interests became more and more scientific. He formulated new theories of asepsis and antisepsis. His operative skill and his gift of teaching made him one of the leaders in the Lyons school. He collaborated in the "Treatise on Surgery" with Duplay and Reclus, writing the articles on the injuries of the bones and articulation. His work on actinomycosis, written in collaboration with Bérand, is classic. The later years of Poncet's life were devoted to the study of tuberculous inflammation. He delineated a type which he characterized as tuberculous rheumatism.

Tenneson, one of the most noted of French dermatologists, recently passed away. He was among those who were originally opposed to the use of Koch's tuberculin. His work on uremic paralysis, on the aberrant forms of zoster, and the relation between erythema nodosum and syphilis and tuberculosis, and his excellent treatise on dermatology have all added to his renown.

5. A Simple and Effective Method for Disinfection of Typhoid Stools. H. Linenthal and H. N. Jones.
6. Cancer of the Lower Lip. J. C. Bloodgood.

**1. Effect of Digitalis on Blood-Pressure and Pulse Pressure.**—C. H. Lawrence points out that in the majority of writings upon digitalis, it is stated that one effect of the drug is to raise the systemic blood pressure, and that for this reason its use is contraindicated in those conditions in which an increase of circulatory tension might give rise to unfortunate results. On the basis of work already done on animals and normal individuals the conclusion has been reached that digitalis causes a rise in blood pressure when administered to individuals suffering from cardiac decompensation. As the result of observations reported on twenty-five cases taken at random from the records of the Massachusetts General Hospital the following conclusions were come to: (1) The effects of various drugs on the blood pressure as determined by experiments on animals do not furnish reliable criteria for the administration of such drugs to man since the effect may be quite different in the latter. (2) The pressure-raising effect of digitalis noted in animals and in healthy individuals does not occur, as a rule, when the drug is administered to individuals suffering from cardiac decompensation. (3) The cause of the cardiac decompensation does not appear to affect the action of the drug. (4) Digitalis preparations may be safely administered to patients suffering from arteriosclerosis, angina pectoris, or nephritic hyperdistension, if cardiac decompensation is present; under such conditions it rarely causes a rise in blood pressure.

**5. Disinfection of Typhoid Stools.**—H. Linenthal and H. N. Jones give an account of testing a method for disinfecting typhoid stools in a practical and effective manner which requires only such utensils as are available in every household and so simple as to require little intelligent effort on the part of the attendant. Such a method was described by Dr. Prausnitz of Austria at the fifteenth International Congress on Hygiene and Demography, held in Washington in September, 1912. The method was devised by Dr. A. M. Kaiser in the Hygiene Institute of Gratz University. It consists of adding enough hot water to cover the stool in the receptacle and then adding about one-fourth of the entire bulk of quicklime (calcium oxide), covering the receptacle and allowing it to stand for two hours. The hydration of the lime generates enough heat to destroy the typhoid organism. Linenthal and Jones believe that this is a simple, efficacious method and should take the place of the various methods now recommended by local boards of health.

6. The Effect of Intraperitoneal Injections of Ozone in Animals Following Infections with Virulent Bacteria. S. E. Finch.
7. Wesley's System of Medicine. W. E. Riddle.
8. A Case of Acute Lymphocyte Leucemia. J. Balligi.

**1. Anoci Association.**—G. W. Crile formulates the objections to ether anesthesia and states that these objections led him and his co-workers to turn to nitrous oxide, an anesthetic pleasant to take, devoid of baneful after results, and serving as a measurable protection against shock, and goes on to point out that to carry out the principle of anoci association requires a careful and expensive technique. The preoperative strain must be reduced by the hypodermic administration of morphine and scopolamine; an inhalation anesthetic must be used to exclude the psychic stimulation of the brain cells in the course of the operation, and the anesthetic of choice should be nitrous oxide, which is unsafe in the hands of any but a skilled anesthetist; a local anesthetic must be used progressively in the course of the operation to protect the brain from local operative injury; and finally the postoperative effects must be eliminated by a local anesthetic of lasting effect. A detailed description is given of the technique in abdominal and goiter operations and full explanations as to why the numerous unpleasant sequences of operations under ordinary anesthesia and

ordinary circumstances are absent after operation under anoci association. Crile states that comparing the last 1,000 operations performed by his associates, Dr. Lower and Dr. Sloan, by his resident staff at Lakeside Hospital and by himself before they adopted the fully developed anoci technique with the last 1,000 operations, they find that in the former the mortality rate was 4.6 per cent., while in the last 1,000 anoci operations the mortality rate was 0.8 per cent.

4. **Hunger Pain and Its Significance.**—J. J. Gilbride says the term hunger pain was first suggested by Moynihan and applied to the pain that occurs when the patient is beginning to feel hungry. Although pain which stimulates it or some of its variations may occur in other diseases, it is nevertheless the most valuable symptom in aiding one to diagnose duodenal ulcer. The pain in duodenal ulcer may be at first confined to the right side of the epigastrium. Later it may be referred to the back or around the right costal margin. When the disease has existed for a long time, when complications have arisen, when adhesions have formed, the pain may be practically constant.

6. **The Effect of Intraperitoneal Injections.**—S. E. Finch reports that ozone, 0.001 per cent. in oxygen dilution, can be introduced with impunity as a continuous current into the abdomen of a normal rabbit until from 20 to 22 milligrams have been passed through the peritoneal cavity. With very high concentrations of ozone, as the use of 0.015 per cent. oxygen dilution, the introduction of but 190 to 200 milligrams without ballooning the abdomen, causes death of a normal animal within 6 to 8 hours of its use. The use of ozone gas within the peritoneal cavity of animals following general peritoneal infection may be without harm to the animal if the concentration is very weak, not greater than 0.001 per cent. by weight and in oxygen dilution. Under the following conditions the animals survive the use of a continuous current of 0.001 per cent. ozone: Use within 3 hours of a general peritoneal infection, limitation of the infection to the peritoneum, a low grade of toxemia; use of a continuous current of the gas, and according to the judgment of the operator, the use of a greater number of milligrams of ozone than would actually be required to kill the bacteria if brought into intimate contact with them; finally the use of but very moderate or no distension upon closing the abdomen. The use of the following concentrations, 0.005 to 0.012 per cent. by weight when introduced into the peritoneal cavity of normal animals, produces symptoms other than those due to the physiological action of oxygen, and in connection with general peritoneal infection, unless the amount of ozone used and the bacteria are nicely balanced and the conditions above mentioned, its use insures a rapid and fatal termination.

**3. Circumcision.**—A. L. Wolbarst defends the rite of circumcision from the attacks of Dr. L. Emmett Holt and the late Professor Mass on the ground that it is an unsanitary procedure. He states that on the contrary, (1) It is a great aid to cleanliness of the genitals. (2) It is a decided prophylactic against infection with syphilis and chancroid. (3) It prevents in great measure the development of venereal warts, herpes, epithelioma, and other growths. (4) It offers a diminished tendency to masturbation, convulsions, and other nervous results of local irritation. (5) It diminishes local complications in the presence of venereal diseases. (6) It makes the "fourth venereal disease" impossible. (7) It prevents the development of phimosis and paraphimosis, with their attendant complications.

4. **Hysteric Blindness.**—L. Newmark reports two cases of hysteric blindness of both eyes in men past middle age. Hysteria is supposed usually to occur in young persons and females, but his experience does not seem to bear out this view. Krön in 1892 found a great preponderance in females, but he overlooked two cases reported by Barkhan of San Francisco in males, which would have made his figures of bilateral hysterical blindness 6 instead of 4 males to 22 females. The figures could then be used to show that one-third of the men so afflicted were to be found in San Francisco. The two cases now referred to, also in California, are still more anomalous, for one of the patients had reached an age equal to the greatest he had found elsewhere reported and the other was yet 6 years older. The occupation of the oldest patient, that of a sea captain, and his age of 60 years, do not comport with the current notions regarding hysteria and the severe headaches from which he suffered were calculated to cause apprehension of organic disease, but writers have pointed out that hysterical blindness has in other cases been especially associated with like brain symptoms. Newmark discusses his cases in detail to uphold his diagnosis of the hysterical nature of the affection.

5. **Esophagoplasty.**—Willy Meyer describes the Jianu operation which he thinks has, to a certain extent, revolutionized the surgery of the lower esophagus. After reviewing briefly former methods of operation he gives an account of Jianu's technique which utilizes the major curvature of the stomach for the creation of a somewhat long tube, one end of which remains in connection with the gastric fundus while the other free end can be drawn up. A new tube of ample size with adequate blood supply and surrounded completely by peritoneum is formed, through which the patient will be able to pass food. If transposed outside under the skin of the thorax the first stage of extra thoracic esophagoplasty has been accomplished. If pulled up into the pleural cavity through a hole in the diaphragm, as proposed by Meyer, it can be used to replace the lower portion of the esophagus after resection for carcinoma. He concludes that intrathoracic esophagoplasty, when properly carried out would seem to be an ideal operation.

**3. Glycosuria in the Course of Affections of the Liver.**—M. Labbé raises the question of the presence of glycosuria in the course of affections of the liver and tries to determine the relationship between hepatic disorders and diabetes. The question is considered under five headings: (1) The glycosuria that occur during the course of hepatic lesions. (2) The hepatic congestions in overfed people. (3) The postinfections or toxic hepatic symptoms. (4) The "diabète sans denutrition" with enlarged liver of the overfed. (5) The hepatopancreatic cirrhosis with severe diabetes. In cirrhosis and other lesions of the liver, cancer cardiac liver, the glycoregulator function is generally disturbed but not sufficiently to cause what may be called diabetes. People indulging in overfeeding, especially with meat, sometimes develop a glycosuria accompanied by hepatic congestion and disturbances in the functions of the liver. After acute infectious diseases a complexus of hepatic disorders accompanied by glycosuria that reminds one of diabetes is sometimes seen. "Diabète sans denutrition" supervenes in those who are in the habit of overfeeding themselves and is often accompanied by an enlarged liver and disturbances in the functions of that organ. Lastly, there is a group of diabetes connected with hepatopancreatic cirrhosis. The diabète bronzé is of this class. Here the glycosuria is severe and accompanied by nitrogenous waste and often by acidosis; the hepatic cirrhosis is well marked; the cirrhosis of the pancreas is revealed by more or less marked signs of pancreatic insufficiency. Hence in these cases there is a simultaneous evolution of a severe glycosuria and of a lesion of the liver and pancreas, but it is impossible to decide whether the liver or the pancreas plays the first rôle in the pathology of the diabetes. Finally Labbé is of the opinion that the name of hepatic diabetes should be reserved for a certain class of cases in which the alteration of the liver is manifest.

**7. Tuberculous Rheumatism.**—U. Raw reports a case of apparently tuberculous rheumatism occurring in a young lady aged 19, of healthy parents. Examination of the fluid from the joints revealed an excess of lymphocytes which is, of course, in favor of tuberculosis as opposed to polymorphonuclear leucocytosis, which occurs in true rheumatism. .Raw has only seen three cases of this rare condition. The first was in Washington, D. C., in 1908, and occurred in a boy aged 14, who was suffering from tuberculous neck glands with secondary pseudorheumatism in both hands and wrists. The second case he saw in Berlin in 1913 at the Rudolph Virchow Hospital and occurred in a girl, aged 17, suffering from tuberculosis of neck glands and lupus. It is of interest to note that these three cases were all secondary to a primary tuberculous focus in the neck glands which is, in Raw's opinion, almost always caused by the bovine bacillus and he can find no record of tuberculous rheumatism occurring in the course of pulmonary tuberculosis which is most frequently the result of infection by the human bacillus. It would seem, therefore, that the bovine bacillus is much more likely to find its way into joints and also into the blood stream, than the human bacillus, which is generally limited in its action to the lungs, larynx, and intestines.

## Muenchener medizinische Wochenschrift.

*December 9 and 16, 1913.*

**Study of Benign Albuminuria.**—Veil reports a case of this sort at length. This was complicated from the very start, and in watching it further elements were recognized. The patient may be summed up as a mass of internal secretory disturbances and psychical peculiarities. Aged 25, he was proved to be a victim of dementia præcox, a subject of vagotomy, orthotic behavior of secretions, albuminuria, status thymicolymphaticus. There was psychosis and Grave's disease in the ascendants. Of interest it is that patient has consulted many physicians, all of whom pronounced him a nephritic, without the least psychical disturbance. A diagnosis which covers the facts is psychoneurosis with chronic albuminuria.

**Nervous Fever in Tabes Dorsalis.**—Siegrist regards this find as extremely uncommon, and as a form of tabic crises characterized by rise in temperature. The number of cases to be found in literature, if we consider only pure crises of temperature is very small. In six cases, including the author's there was absolutely nothing present to suggest infection. In a small number of cases the temperature rise was clearly due to complications. In the author's case the temperature crisis pursued a course parallel with that of pain crises. The only cause attributable was the disease itself, either through irritation of the centers for warmth, absorption of toxic matter, etc. The fever crises show very markedly on a temperature chart, and the highest temperature reached was 39.0° C.

**Cornelius Nerve Point Doctrine and Swedish Massage.**—Port states that Cornelius published his doctrine on nerve points in 1905. The method has never come into general use, and the author only stumbled upon it by chance. These are simply sensitive pressure points, responsible to a large degree for many phenomena of neurasthenia and hysteria. According to Cornelius the condition has a purely mechanical origin from a chronic obstacle to the passage of nerve impulses in the shape of new formed connective tissue. This theory promises well if we limit ourselves to the results of treatment. Massage and excision of certain tissues, scars, calluses may be cited. Thus a painful "viewpoint" represents a mechanical obstacle to the passage of nerve impulses. A study of Swedish massage, when compared with the preceding shows many points in common. The teachings of Swedish massage have never penetrated into Germany, and Cornelius doubtless has never encountered them.

**Malapplication of Albumin Water as a Nursling Food.**—Lust concludes an article on this subject, in which he claims that when the digestive tract of the healthy baby is irritated by the exhibition of egg albumin in water, how much more marked must this be when the nursling stomach is already acutely disordered. It is not, however, the direct effect of the albumin which is to be feared; it is the remote effect in causing vasomotor disturbance. Causes have been seen in which egg albumin merely left on the baby's lips has caused both local and general symptoms severe in character.

**Operative Nearthrosis.**—Helferich refers to the formation of new articular surfaces in diseased joints to the extent that mobility results. Attempts in this direction began with the authors, Rochet and Lentz, independently, in 1893-4. The authors' case, in the temporo maxillary articulation, ended in marked improvement. The material interposed was taken from the temporal muscle. Others followed their wide resections of joints with some form of interposing material. Finally König announced that the latter was unnecessary. He was soon proved wrong and such interposition became permanently incorporated in joint surgery. In 1905 the author obtained a successful result in the hip joint, preventing ankylosis by the interposition of a flap of gluteal muscle. This crude procedure was

very far from establishing a complete new joint. For this purpose one would naturally have in mind arthrolysis, osteotomy, or transplantation of actual articulating surfaces (Lexer). It is doubtful, however, if the latter could become a routine procedure, and that interposition of tissues must replace it in that capacity. The author finds in literature about 300 cases treated in this manner, not including twenty operations on the jaw. This great material has chiefly accumulated in the last three or four years. The author analyzes this material in part. Among Americans he mentions only Murphy and Baer. He differs with Murphy as to the difficulty of the operation which makes it a task for the master surgeons, and thinks enterprising young operators should be able to master the technique. Fascia, fat, muscle tissue, condyles, each has its sponsors among surgeons.

**New Viewpoints for the Clinical Use of Camphor.**—Hötzel writes briefly on this subject which has recently been considered by Leo (No. 43 of this year's *Wochenschrift*). He writes with especial reference to croupous pneumonia. The author saw a severe case of migratory pneumonia which promptly healed after injections of camphorated oil. The effect was as startling as that produced by serotherapy in diphtheria. For the past three years he has employed this treatment at the outset of every case of pneumonia. Ten c.c. of the oil is injected over the skin and repeated at certain intervals. On the third or fourth day a lysis occurs and in two days more the disease is not noticeable. Thus far in three years the author has treated thirty cases of croupous pneumonia with one death. The latter subject already had myocardial degeneration. Never save in his first case did he appear to conquer the disease at a stroke. In all the other recoveries the disease ran its course. He therefore looks further for a substance to sterilize a patient at once. He never pushed camphor to great doses in order to accomplish such a result, for camphor has somehow acquired a reputation of causing hemorrhage of the lungs (in his one fatal case the patient's lungs bled freely), due perhaps to extreme dilatation of the blood-vessels of the lungs. But to this property we may owe the beneficial action of the drug, which thereby promotes a local leucocytis, the enzymes set free at the time dissolving at once the exudate. Whoever wishes to use the remedy in pneumonia should inject 10 c.c. strong camphor oil twice daily.

---

### Deutsche medizinische Wochenschrift.

*December* 18, 1913.

**Cure of a Case of Pneumococcus Meningitis by Ethylhydrocuprein.**—Wolff and Lehmann have succeeded with the aid of this synthetic prepared originally with the intention of antagonizing the pneumococcus wherever found in curing a case of meningitis due to the latter germ. The patient was a nursling and the drug was injected directly into the spinal canal and cerebral ventricles. Before the newer remedy was tested, pneumococcus serum in the cord and urotropin in massive doses had been administered. The meningogenic vomiting was indirectly responsible for the heroic treatment as drugs would have been vomited. The veins were also too small for intravenous methods. The almost hopeless outlook for recovery by ordinary measures thus led to the ventricular puncture in addition to the spinal injections. The authors will report the case in greater detail.

**The Heine-Medin Disease.**—Cassel gives some data and impressions based on a recent small epidemic of acute poliomyelitis and polioencephalitis. The disease is now notifiable in Prussia, but a certain fraction of the profession still refuse to admit the validity of the recent claims put forward. Old practitioners have failed to see any evidence of contagion, have never seen any plurality of incidence in large families, or close settlements, refuse to believe the new teachings. Younger men, on the contrary, see in the disease a veritable plague able to attack hundreds within the same territory. This view shared by the author makes prophylaxis the chief duty. Actual cases should be isolated for from four to eight weeks and otherwise the scheme pursued for scarlatina, etc., should be carried out as far as mere disinfection goes. We know nothing of the carrier problem here.

**Need of Care in Handling Mesothorium.**—Allmann records the following case: in a laparotomy for ovarian cancer, 160 mg. mesothorium were inserted intratumorally, an ordinary hole having been bored for its reception. The remedy was first enclosed in glass tubes, these in turn within silver tubes. These tubes are normally covered with a protective of nickeled brass, but to secure the stronger action, the author stripped this off and substituted gauze, thin rubber, and again gauze, making a triple covering. After renewing the external gauze, the filter was placed in a recurrent nodule in the vagina which was then bleeding. As the silver-coated tubes were being inserted one tubule of mesothorium was melted, but in the middle of the tube, the glass remaining intact. This tube was in use for four months, the probability being that the rays had attacked the silver and denatured it. However, the tube did not break when placed within an orifice, which showed that the glass and silver remained intact. While nothing detrimental occurred in this case a friable silver tube in breaking suddenly might fill the space with broken glass.

**Diagnosis of Duodenal Ulcer.**—This article by Bier is to be noted chiefly because it is part of a mild international warfare between the Germans on one hand and the English and American surgeons on the other. The warfare has not yet reached personalities and it is to be hoped that nothing of this sort will occur. Moynihan is made the chief protagonist on his side, because his book has been translated into German and widely read. Bier, Kehr, and other heavy German operators criticise to a greater or less extent the teachings of Moynihan, Mayo-Robson, and Mayo. The whole debate seems to be due to the larger number of cases reported in America and England than in continental Europe. This would seem to argue a greater frequency or a superiority in diagnosis, or a great preponderance in resort to the knife. Bier admits that the foreigners stole a march in operating years before the Germans. Moynihan's cases compared with a German series show no difference whatever. Bier, however, has seen many such case histories and has even made exploratory incisions in some of them without finding an ulcer, but some condition quite different. A list of these he gives in detail. In two cases only did he mistake in a diagnosis of duodenal ulcer. Again, when ulcus duodeni was found at autopsy, there was very often no history pointing to it. In the closing paragraph he gives Moynihan full credit for a great practical introduction to surgical diagnosis and operative surgery.

---

**The Cerebrospinal Fluid in Infantile Tremor.**—Mariano Lo Re notes that Durante characterized this tremor as an atypical form of tetany. Rotch and Holt attribute it to a nutritional defect. In three cases studied by the author the cerebrospinal fluid showed a slight increase in the amount of albumin and a moderate lymphocytosis. These changes he regards as evidence of a mild meningeal reaction resulting from intestinal toxemia—*La Riforma Medica.*

## Insurance Medicine.

**Special Features of a Medical Director's Work.**—Dr. M. O. DeVaney, Associate Medical Director Indianapolis Life Insurance Company, frankly discusses this subject from two viewpoints, namely, what may be expected of the Medical Director himself, and his attitude toward his workers. He thinks that the medical director who is not in himself a stimulant to the business of his own company is more or less a failure; that he should be a living, vital, active force in the official staff of the company. His position, being one of trust, requires of him not only medical knowledge but honesty, sound judgment and unlimited diplomacy. It is the natural tendency of men in this position to become autocratic and to lose respect for the agency force—often with ample cause; but the worth-while agent has great respect for the company that deals honestly and squarely, and it is the medical director who can impress him with the fact that his company not only gives square deals, but expects the same from him. The medical director should mingle as freely as possible with his agents. With the relatively small company, it is not impossible for him to establish a human touch with them, and to show appreciation of their work. The successful field man is a high-tension individual, and, like all high-tension machinery, must be handled with care. The man who has the ability to keep his company's banner in the field is no mean fellow. Dr. DeVaney enjoins upon the medical director that his field men are entitled to prompt service and quick decisions.

It is only through the eyes of the agent, local examiner, and inspector that the medical director views the majority of the applicants. On the facts from these sources he is dependent for his decisions, so it is wise for him to visit the field often with eyes open and ear to the ground. The handling of medical examiners is another special feature for the medical director's consideration. There is naturally a somewhat close sympathy between the agent and the local examiner, and it is to be desired that friendly relations exist between them; but the examiner's friendly feeling must not interfere with his duty to the company, which always calls for an unbiased statement of the material facts. The diplomatic, ingenious medical director may offset any undue personal influence from the field by keeping himself in close personal touch with the examiner.

He should never lose an opportunity to meet as many of the examiners as possible socially. It is at social meetings that men become best acquainted. When the medical director looks over the reports his personal acquaintance with the examiner will better enable him to interpret the answers given, and the acquaintance will be remembered by the examiner when he picks up the examination blank to be filled out for the special company the medical director may represent.—Medical Section, American Life Convention, August, 1913.

**Economic Influence on the Medical Profession of the Periodic Examination of Insured Lives.**—Eugene Lyman Fisk, Medical Director, Postal Life Insurance Company, shows that while the practical commercial spirit of the age has infected individual members of the medical profession, it may be truly stated that the profession as a whole is laboring with might and main to reduce the morbidity from which its revenues are drawn. Even the surgeon is urging the earlier, simpler and less expensive operations to the end that patients may be saved from heroic operations and big fees. In these efforts there is no selfish altruism, but the real simon-pure article.

Indeed if scientific progress continues unchecked, the physician, as we now know him, may disappear as completely as the overland stage-coach driver, the peculiar social service that he renders becoming no longer required. It is evident that already a change is impending in the relations between physician and public. The physician is taking the public more and more into his confidence, and the public is looking to the physician for guidance as to how to keep away from his office. After all, the labor of preventing disease resembles very much the task of Sisyphus. As one class of diseases is conquered another takes its place. It is to be remembered that the diseases conquered are of the self-limiting type, those wherein the human organism, if possessed of reasonable resisting power, summons to its aid from its own tissues and organs the antidote and cure. But the diseases that are on the increase—those of the degenerative class—are not so characterized. They tend to progress to a fatal ending, unless there is some change in the habits or environment of the patient, and complete restoration of condition is often difficult, if not impossible. So the value of a periodic inspection of the apparatus to be guarded and conserved becomes logically evident. Thus it follows that the physician must spend less time in mastering an obsolete pharmacopeia and more time in accumulating knowledge of the influence of living habits, in order that he may keep his patients out of trouble, instead of trying to perform impossible tasks on worn-out and broken-down tissues. In this matter of the newer medical practice, directed toward prevention rather than cure, the periodic examination of insured lives will prove a powerful accelerating influence. In the interval of adjusting the profession to the newer standards it will prove an economic factor of no mean importance, not only as regards the fees that will be distributed, which would amount to some millions of dollars, but in the matter of linking the public to scientific medicine and offsetting the evil influence of the mystics and layers-on-of-hands who flourish so surprisingly in this alleged materialistic age.

If all old-line policyholders should seek these periodic examinations either through the companies' facilities or by their family physician, ten millions of dollars would be distributed annually to examining physicians. When we consider the possible future development of these activities in the life insurance field and their reflex influence on the general public, we may look forward to a time when the principle of periodic inspection of the human body will be applied to the entire population, whether by government, corporations, private institutions, or family physician equipped for this purpose. This work must naturally come to the physicians. With the public brought regularly and automatically into contact with scientific medicine, there is reason to believe the gain would be mutual. Less money would be paid on account of illness, but more money would be paid for keeping well.—*Lancet-Clinic*, August 9, 1913.

# Book Reviews.

CANCER OF THE BREAST. An Experience of a Series of Operations and Their Results. By CHARLES BARRETT LOCKWOOD, F.R.C.S. (Eng.), Consulting Surgeon to St. Bartholomew's Hospital, etc. Price, $3. London: Oxford University Press, 1913.

FEW books are more valuable in estimating the end results of modern surgery than those which contain a plain and unvarnished account of the operative methods and results of an individual surgeon trained in scientific methods and frank in the presentation of both the pleasant and the unpleasant aspects of his surgical practice. This volume contains a good deal of extremely interesting material gathered from a large series of operations on the breast and discussed with sanity and judgment. The author is one who has long insisted upon the value of the thorough microscopical study of tumors, not only after, but, by means of frozen sections, during the course of an operation. Only by this procedure can extensive removal of benign tumors be avoided and the early and successful treatment of small carcinomata be secured. Most of us would be glad to pass over the after history of fifty per cent. of operations on the breast, but unless we face the facts the percentage of operative successes cannot possibly be increased. There is considerable discussion along this line in the sections on the removal of recurrences in the neck, injury to the thoracic ducts, mortality, persistence of edema after operation, and neuritis, with finally a discussion of the ultimate results and the relations between the picture and the clinical course of the tumor. No surgeon can fail to obtain information of value from a perusal of this book.

PROTEIN SPLIT PRODUCTS IN RELATION TO IMMUNITY AND DISEASE. By VICTOR C. VAUGHAN, M.D., LL.D., Dean of the Department of Medicine and Surgery of the University of Michigan; VICTOR C. VAUGHAN, JR., M.D., A.B., Junior Attending Physician to Harper Hospital, Detroit, in Charge of the Tuberculosis Work of the Detroit Board of Health, and J. WALTER VAUGHAN, M.D., A.B., Junior Attending Surgeon to Harper Hospital, Detroit. Price, $3 net. Philadelphia and New York: Lea & Febiger, 1913.

VAUGHAN, SR., began his work on the chemistry of the bacterial cellular substance many years ago, and papers from his pen dealing with this subject have appeared from time to time. The work has now reached such a stage as to demand a more adequate presentation, and this volume summarizes the results of his investigations and the theories which have developed from them. The matter is largely new and is perhaps best condensed in the form of twenty-four important points which the authors collect in the introduction. These points are: (1) Bacteria are essentially particulate, specific proteins. (2) All true proteins contain a poisonous group. (3) The chemical nucleus does not become a poison until stripped, in part at least, of its secondary groups, and the intensity of its poisonous action is determined by the thoroughness with which the secondary groups have been removed. (4) When proteins are submitted to the action of disrupting agents there is the possibility of the chemical nucleus being set free more or less completely, and to the extent that it is detached it becomes a poison. (5) The pathogenicity of a bacterium is not determined by its capability of forming a poison. (6) The pathogenicity of a bacterium is dependent upon its ability to grow and multiply in the animal body. (7) Any foreign protein which can grow and multiply in the body of a given animal may prove pathogenic to that animal. (8) The infectious diseases result from parenteral protein digestion. (9) Natural immunity to any infection is due to inability of the infecting agent to grow in the animal body. (10) The immunity which is due to recovery from an infection is the result of the development in the body during the course of the infection of a specific ferment, which immediately destroys the infection on renewed exposure. (11) Immunity established by vaccination is similar to that induced by an attack of the disease. (12) Protein sensitization and bacterial immunity, apparently antipodal, are in reality identical. (13) Protein sensitization consists in developing in the animal body a specific proteolytic ferment, which digests the same protein on reinjection. (14) When a foreign protein is introduced into the blood of an animal it soon leaves the circulating fluid and is distributed throughout the tissues. (15) Vaccines are protein sensitizers. (16) Toxin immunity and bacterial immunity are radically different. (17) The protein poison is not a toxin. (18) The protein poison is not specific. (19) The tolerance which may be secured by the protein poison is not specific. (20) The sensitization developed by a protein is specific, but is not due to the poisonous group in the protein. (21) Different proteins find in the body certain predilection places in which they are most prone to accumulate. (22) The symptoms of a given disease are largely determined by the location of the foreign protein. (23) The poison elaborated in all the infectious diseases is the same. (24) When a cell in the animal body is permeated by a foreign protein, the former strives to elaborate a ferment by which the latter is destroyed.

The majority of these points are quite satisfactorily established by the authors' experiments. To only one would we care to take any serious exception. Point 13 presents the claim upon which they base their theory as to the causation of anaphylaxis. Throughout the discussion of their experiments and their deductions therefrom the authors make no reference to the factor of time, except on page 341, where they say that it holds equally well against Nolf's theory. Under certain conditions guinea pigs succumb to anaphylaxis with a rapidity which would seem to preclude the possibility of its being the result of ferment action. Moreover on page 365 they state that examination of the blood fails to reveal any diffusible biuret body within fifteen minutes of the reinjection. This is but one objection, it is true, but it would seem to be an important one. The whole work fits very well with Abderhalden's investigation into parenteral digestion and is a distinct and valuable contribution to the study of immunity. It is naturally to be expected that in the course of time some of their claims will suffer some modification, but many are already firmly established and are likely to remain so. To any who are interested in immunity the book should prove of great interest and profit.

THE ADMINISTRATIVE CONTROL OF SMALLPOX. How to Prevent or Stop an Outbreak. By W. McC. WANKLYN, B.A. Cantab., M.R.C.S., L.R.C.P., D.P.H., Fellow of the Royal Society of Medicine, Fellow of The Society of Medical Officers of Health, Referee in the Diagnosis of Smallpox, and Medical Superintendent of the River Ambulance Service (Smallpox) of the Metropolitan Asylum Board. Price $1.10 net. London and New York: Longmans, Green & Co., 1913.

THIS is a companion, volume to Dr. Wanklyn's "How to Diagnose Smallpox." It comprises the principal administrative details which must be put into practice in order to cut short an outbreak of smallpox. Dr. Wanklyn gives the latest methods of diagnosis, of the removal of cases to the hospital, of disinfection and of close observation of contacts, the importance of these methods increasing in proportion to the decline of vaccination. A number of cases are reported in which smallpox eluded the vigilance of the English port sanitary officers. These make the reader agree with the distinguished writer that the successful prevention of epidemics depends on a tireless attention to the details of action and on a well prepared plan.

ANATOMY, DESCRIPTIVE AND APPLIED. By HENRY GRAY, F.R.S., Fellow of the Royal College of Surgeons, Lecturer on Anatomy at St. George's Hospital Medical School, London. New American Edition, thoroughly revised and re-edited, with the ordinary terminology followed by the Basle anatomical nomenclature, by EDWARD ANTHONY SPITZKA, M.D., Director of the Daniel Baugh Institute of Anatomy and Professor of General Anatomy in the Jefferson Medical College of Philadelphia. Illustrated with 1,225 engravings. Price, $6 net. Philadelphia and New York: Lea & Febiger, 1913.

THE special feature of the edition is the introduction of the terms of the Basle anatomical nomenclature following the ordinary anatomical terms. This is a valuable addition and should serve to increase the usefulness of this widely known text-book. The paragraphs dealing with applied anatomy are particularly helpful. In every respect the work shows the imprint of careful revision. The illustrations, including many in colors, are characterized by their clearness, a quality enhanced by the engraving of the names of the parts directly upon the illustrations. The index contains both terminologies.

# Society Reports.

## NEW YORK ACADEMY OF MEDICINE.

*Stated Meeting, Held December* 4, 1913.

THE PRESIDENT, DR. WILLIAM M. POLK, IN THE CHAIR.

**The Education of Crippled Children.**—Dr. G. G. Davis of Philadelphia presented this paper. He stated that although he did not feel altogether competent to speak on this subject it was one that appealed to him so strongly that he had decided to do what he could to further the progress of the study of this problem, which was at present in an unsettled, early, and primitive stage. Educators had not succeeded in establishing any standard for the education of the normal child, but, in addition, they had the solution of the problems arising from the crippled children. It was evident that the methods employed in the two classes must be different. The crippled children formed an intermediate class between the totally well children who could be driven and actually flourished under it, and the sick children who needed rest, and soothing and supporting measures. The crippled child should have a distinct, separate, special method of treatment adapted to his peculiar needs. The education of the crippled child was intimately associated with his bodily care; the two should be considered together. They were, therefore, confronted with the following problems: 1. Maintenance. 2. The care and treatment of the disabilities of the crippled child. 3. His general education. 4. Character formation or moral education. 5. Vocational training. 6. Later supervision. The number of cripples was so great and their education and maintenance so expensive that in the present state of society it had been found necessary to establish institutions for them, even though the substitution of institutional life was not desirable from many points of view. It was the duty of the institution to resemble home life as far as possible. The question of maintenance should be more carefully looked into than had been the case in the past. The child should be provided with such nourishment as would tend to improve and conserve his health. There was a great field for usefulness in their modern Social Service in the endeavor to meet this need. As to disabilities, if the child could walk to school the problem of its education was simplified. Orthopedic treatment was of the first importance. The more successful it was the more it broadened the child's capabilities. For this reason it was essential that institutions for crippled children should be equipped so as to provide the constant orthopedic treatment that these cases required. Even in the day schools there should be some one capable of doing the more simple dressings and adjustment of apparatus that might be needed. The orthodox orthopedic hospitals might relieve the educational institutions of a certain portion of this work, but not all of it. As to general education, the crippled child had greater need of a good general education than the normal child, as the latter had greater opportunities of acquiring knowledge. For education to be successful it should be sufficiently thorough for the child to eventually become self-supporting. The wider the education the greater would be the choice of occupations in later years. If the State paid for the common school education of the normal child it should also contribute to that of the cripple. Parents were apt to be neglectful and to allow a crippled child to grow up ignorant; they should be taught that this was an error. Family teaching was one of the greatest value and when children were in the hospitals, teachers were now provided for them during their stay. To care for the outpatients they had social workers and the day schools to which the children were brought and again taken to their homes. It was not possible to teach cripples in the same manner as well children. Their disabilities were so varied that it was necessary to devote a large amount of individual attention to each child. Therefore, a larger number of teachers was necessary for a given number of children than in the ordinary public school classes. The classes of crippled children should not be so large. They should decide in each individual case when it was safe for the general health of the child to sacrifice a certain portion of its outdoor life for indoor instruction. Although both the Montessori and Froebelian systems had their good points, one should use judgment in imposing them on the individual cripple. As to character formation or moral education, it should be emphasized that while intellectual development was of importance it was insignificant as compared with good character. The problem was how to rear the cripple so that he should develop into an industrious, unselfish, honest, and reliable citizen. How could they ever be made self-supporting if they were lazy and unwilling to work? How could ambition be infused into them so that they would endeavor to help themselves instead of being content to be parasites all their lives? Many things influenced the formation of character, but precept and example were the most powerful. If the cripple could be surrounded by good associations that would be the best guarantee that he would develop correctly. The greatest influence was exerted by good home life. To take the crippled child away from good and loving parents and to place him in an institution was a great mistake. If charity must be doled out it was better to dispense it in the home. No child should be placed in an institution that could possibly be kept out. If an institution was to stand *in loco parentis* the greatest care should be exercised to see that all the officials and teachers and employees—everybody who came in contact with the children—should be of the best possible character so that the child should insensibly acquire the views and habits of thought which would be best for him in the future. The children should not be handled in masses, but should be brought into personal contact with their caretakers and teachers. Persons suitable to fill such places were not easy to find. As to vocational training, manual training was not necessarily vocational training. Its primary object was development. It was to teach children to do things for themselves, to think, and reason, and accomplish something by their own unaided efforts. It was a mistake to restrict vocational training to a few stereotyped forms and thus to confine all to a narrow choice. The first step was to find out what was most desired by the child and what he was best fitted for, and then an effort should be made to fit him into that line. In regard to subsequent supervision, the speaker said that many cripples as they approached maturity lost their home ties and were left to fight their own way alone, when they were apt to retrograde or fail entirely. They should be made to feel that there was someone who was interested in them and who was watching their progress. They should be encouraged to keep in touch with their *alma mater* until they had definitely established themselves and formed a circle of friends elsewhere. The adult cripple had been too generally treated as a pauper, but if through State aid or private beneficence a crippled child had been reared and fitted for the duties of life it was certainly their duty to give him that moral support that every beginner in the struggle for existence needed to enable him to safely pass over the bridge which connected the productive and the non-productive periods of life.

**Industrial Training for Cripples.**—Dr. AUGUSTUS THORNDIKE of Boston said that industrial training in a special school probably began in America when the Industrial School for Crippled and Deformed Children opened October 4, 1893. The growth and progress of the school had been uniform. Instruction was given in the following industrial branches: sewing and dressmaking, basket-making, cane-seating, cobbling, cooking, typesetting and printing. One or two hours of the time allotted to school work was spent each day in the open-air schoolroom. The Massachusetts State Hospital School for the Care and Education of Crippled and Deformed Children of the Commonwealth, authorized by the Legislature in March, 1904, was formally opened by the Governor's proclamation December 1, 1908, the first pupils being received January 14. The school accommodated at present two hundred and sixty crippled children between the ages of five and fifteen, although a few of them were older. Instruction in the first eight grades of the public school system was given, mostly in out-of-door schoolrooms, to small groups for short periods, the younger children receiving instruction for an hour and a half a day, and the older for two hours. Sewing was taught in graded classes, also drawing, stenciling, painting in water colors, and sloyd carpentry. In addition to this, small groups were instructed in printing, cobbling, making moccasins, carpentering, house painting, steam-fitting, electric wiring, the care of steam boilers and engines, and a number of the older boys were taught farming, both the care of livestock and gardening; while the older girls learned domestic science in a small cottage, where they did all the housekeeping and housework. The first class grad-

uated last year, and they, together with many who had left the school without completing the course, were at work at various occupations. In closing Dr. Thorndike alluded to a Boston society formed to secure employment for cripples—the Kings Chapel Club for the Handicapped.

Mrs. Henry Goldman described the Crippled Children's East Side Free School, which had been created twelve years ago. The purpose of this institution was to give crippled children an education, to better their physical condition, and to render them self-supporting by means of manual training. During the first six years of the existence of the society, classes were conducted in elementary training with good results, whereupon the needs of this neglected class were brought to the attention of the Board of Education with the result that there were to-day classes for cripples in many of the public schools in the city, and greater provisions would no doubt be made in the near future. Under a staff of able physicians an infirmary was conducted in connection with the school and there was hardly a child in the school that had not for months undergone medical or surgical treatment of some kind. Dr. Wallace could give a more satisfactory report of this part of the work from a professional standpoint. The school had a trained nurse and three assistants who bestowed individual attention on each of the 230 pupils. It was most important that physical development should form a part of the curriculum of every institution for crippled children. The great and important aim of their efforts had always been manual training, adapted to the needs of the crippled children. Eight years ago they had organized a workroom with but two girls. By careful and proper training they now had 40 workers who had become producers of needlework and accurate machine work. Two of their own girls were now earning from fifty to sixty dollars a month as assistants to the manager of the workroom. The receipts of the workroom this year were over $10,000, and almost $5,000 had been paid to the workers in wages. No doubt better results could be obtained if there were ways and means of bringing this work before the public.

Miss Grace S. Harper, general secretary, King's Chapel Committee for the Handicapped, Massachusetts General Hospital, Boston, said there were a few points which had been touched upon and which she would like to emphasize as most important from the main point of placing and "after care" for cripples. The formation of character and stimulation of ambition from as early an age as possible were quite as important as education. If a crippled person was turned out into the industrial world—and needed to earn his living, he must also be able to get along with his fellow workmen and fit into his job. This lack of character and mental warp which was so common among cripples had been their greatest handicap in the successful placing of them. Dr. Richard Cabot was the means of starting the King's Chapel Committee for the Handicapped in Boston. The problem, as it seemed to him at the time, consisted of two things to be done—first, to find out what trade and occupations could be performed by persons variously handicapped; second, to find employers in these industrial shops who would be willing to give such persons a trial. This left the putting of the man into the job, and here was where the question of lack of character—and the mental outlook had proved to be the greatest obstacles. Much of the fault for this difficulty lay with the community and much with the parents. She personally would hesitate to take too much of the responsibility from the parents, by providing boarding schools, inasmuch as the children had to return to their homes when of age and the parents would not then be ready to maintain the discipline and teach the attitude of self-reliance at the most critical time. She thought that most schools might do a great deal in the way of teaching to the parents themselves. Many of them saw no farther than the present need and yet were intelligent when shown the almost absolute certainty that the crippled boy or girl was going to outlive his elders, and at some time would need to earn his living. If he was allowed to be dependent until past the age of adaptability he would probably become a beggar or a pauper. The teaching of every crippled boy or girl a trade or skilled occupation of some kind was another most important need. Many schools gave sloyd and occupational training, but few offered opportunities for learning a trade which would enable the pupil to obtain a position. She read an article a few nights ago, drawing attention to the thousands of unskilled boys and girls thrown on the market each year and to the constantly increased demand for skilled workers. This was a plea for training for the average normal boy and girl. If able bodied children needed such training, how much more so did the crippled ones who had little choice or selection? And yet they were educating many and turning them out without the essential training which would give them a chance to earn their bread and butter. The problem of placing cripples after leaving school was a difficult one and so far not much concentrated effort had been made in this country. Their committee had now had two years' experience which though slight had brought out many points: firstly, that little could be done without personal work for each individual. The worker had to establish friendly relations and in many cases gave the advice and steadying hand which should have come from the parents. Secondly, when a boy or girl had been placed in a position, the interest and close touch with him must be continued for some time. The cripple was usually a child for a much longer time than the average person. When it came to decisions, adjustments, and compromises to others a small matter would be the means of his losing a position which it had taken time and expense to find and which often could not be found a second time.

Foreseeing these difficulties and being ready to meet them meant forming a habit of "sticking at a job" which might in time become permanent. Miss Harper felt now, after their experience, that a year was not too long a time to plan for "follow up" work, that was if one's efforts were to mean permanent help in each person's life.

---

## NEW YORK NEUROLOGICAL SOCIETY.

*Regular Meeting, Held October 7, 1913.*

The President, Dr. Smith Ely Jelliffe, in the Chair.

**Tumor of the Spinal Cord.**—Dr. H. Climenko reported two such cases, and showed the specimens. The first case, which he said was an instance in which syphilis could mask the diagnosis of a tumor of the cord, was that of a married woman, a Jewess, 55 years old; a native of Austria. When she was admitted to the Montefiore Home, on November 17, 1911, she stated that both of her parents had died in the forties, her mother of some wasting disease of many years' duration. One brother died of cardiac disease. There was no history of miscarriages in the family. Her personal history was that she was the youngest child, breast fed; that she had convulsions in early childhood and was always of a weak and delicate constitution. Her menstrual history was negative. She married at the age of 21; she was the mother of nine healthy children and had never miscarried. About four years after her marriage she was treated for cystitis, and ten years ago she had a superficial ulceration of the left leg. Her present illness, dating back about fifteen months, was insidious and progressive. She first suffered from numbness and tingling and tugging sensations, commencing in the soles of both feet and gradually extending up to the hips. Shortly afterward she developed pains in the region of the mid-spine radiating downward into both legs. These were more or less constant. Following these, there was weakness and stiffness in both legs which was preceded by a girdle sensation in the lower abdomen. About three months later she lost the power to walk, and two months prior to her admission incontinence of both the urine and feces developed. A few weeks ago she noticed tingling sensations in the little finger of the right hand. There was no history of diplopia, headache, vomiting, or convulsions. When Dr. Climenko first saw the patient, at the time of her admission to the Home, she could neither stand nor walk. She lay on her back and could sit up only with difficulty. Both lower extremities were flexed and extremely spastic. The double Babinski, Oppenheim, Mendel, and Bechterew reflexes were present. There was double ankle clonus and both knee jerks were very lively. The lower abdominal reflexes were absent. The various reflexes of the upper extremities were present and normal; the pupils reacted to light, accommodation and pain, and consensually. The gross motor power of the active movements in the lower extremities was greatly diminished and carried out very sluggishly. The passive movements were difficult to carry out, due to the enormous spasticity. The spine did not show any deformities, but there was marked hypersensibility to pressure over the tenth, eleventh, and twelfth dorsal spines. The cranial nerves were negative. There were marked sensory disturbances,

extending from the mammæ downward anteriorly and posteriorly. An examination of the blood gave a positive reaction to the Wassermann test. The cerebrospinal fluid was negative, but showed an increase of globulin. The patient was given two full doses of salvarsan and many intramuscular bichloride injections, after which her condition was slightly improved. On May 20, 1912, after a careful study of the sensory disturbances, and influenced by the marked spinal tenderness, a diagnosis was made of a constant lesion within the spinal canal, causing pressure on the cord. The patient was operated on by Dr. Charles A. Elsberg on June 14, 1912, when he removed an elliptical, cauliflower-like tumor, situated at the level of the ninth, tenth, and eleventh dorsal vertebræ, and measuring ¾x½x¼ inch. Pathologically, this proved to be an endothelioma.

The second case reported by Dr. Climenko was that of a widow, 52 years old, born in Russia of Jewish parents, who entered the Montefiore Home on March 21, 1913. In her case the symptoms, which pointed to a lesion in the upper segment of the cord, were such that an operation could not be entertained. She died on July 6, 1913, and the autopsy showed a tumor in the cervical region, the cord here being enlarged throughout the entire length to about twice its normal thickness. Pathologically, the lesion was a gliosarcoma, with resulting degeneration of the cord.

**A Case of Manic-Depressive Psychosis in a Child.**—Dr. M. S. Gregory presented a girl, ten years old, who was born in Austria and came to this country with her parents about three months ago. No history of a pschosis or a neurotic taint in the family or its collateral branches was obtainable. The patient was the third of four children, two of whom died in infancy. Her childhood was apparently normal, and during that period she had the usual diseases, without complications or sequelæ. She was considered an average scholar, and her deportment showed no abnormality. She was bright and cheerful, took an active interest in play and associated with children of her own age. However, she was easily angered and excited, and unduly sensitive. She was an only daughter. The child's parents stated that she was perfectly well until the early part of August, 1913, when she experienced a great disappointment because her mother would not permit her to go to a party. On the following day she was unusually quiet and sad, complained of headache and refused food. She insisted that she was weak and had a pain in the cardiac region. She would remain seated in one place without showing much interest. On August 24, 1913, when she was brought to Bellevue Hospital, a physical examination revealed no objective evidence of a neurological disorder. The pupils responded to light and accommodation; the optic disks were normal. The knee jerks were active and there were no sensory disturbances nor hysterical stigmata. Mentally, she was profoundly depressed and remained in the characteristic attitude of flexion, with head bowed and body bent forward. Her general movements were slow and delayed. She said nothing spontaneously; answered a few questions to the point, but in a rather low tone of voice and after some deliberation. She complied with the usual requests, although slowly. When asked what ailed her she complained of headache and pain in the stomach; said that she could not walk and wished to go home. She would calculate slowly, and occasionally, when she made mistakes and her attention was called to them, she would rectify them. She was well oriented and gave a good account of herself, memory for both remote and recent events being good. There were no hallucinations nor delusions. In the ward she would sit quietly by herself, manifesting no initiative. She took food when it was given to her, but never asked for anything nor expressed any desire. However, she seemed to be in touch with her surroundings and apparently took notice of what was going on about her. She remained in this condition for several days, but gradually improved, so that on September 13, about three weeks after admission, she was taken home contrary to medical advice. Her mother stated that when she returned home she was in fairly good condition for a few days, but that her depression soon returned. She was readmitted to the hospital a week later in a condition much the same as that on her first admission. However, she soon began to improve and at the present time she was fairly active, smiled occasionally, spent her time in playing with picture blocks and puzzles, and took outdoor exercise, but she was still quiet and was rather slow in her movements. She did not talk spontaneously, but when addressed she smiled and answered questions in a low tone of voice. She said she now felt well and was anxious to go home. The Vinet-Simons test showed her scale of intelligence equal to nine and a half years of age. Manic-depressive psychosis, Dr. Gregory said, was apparently very infrequent in childhood. At least, the literature was very meager. It was possible that the disease was more frequent than suspected and that such cases were often unrecognized and mistaken for other disorders. Very often the depression might be associated by the parents and even by the family physician with the bodily condition of the child, and these cases naturally rarely came to the attention of the psychiatrist. During the past eleven years, the speaker said, he had seen only four cases under the age of twelve years. Manic-depressive attacks, however, occurring between the ages of twelve and fifteen were comparatively frequent. The youngest of his four cases was a girl of seven, who had the manic phase of the disease, which lasted six weeks and ended in recovery. In another, a boy of eleven, the disease followed a severe fall. He had alternate attacks of depression and excitement, each lasting a week. He recovered in five weeks. The third, a boy of twelve, manifested an attack of excitement of two weeks' duration, with complete recovery. It was of interest to note that in all of the cases mentioned, the attacks were of rather short duration, which coincided wih the observations of Ziehen and others.

Dr. Jelliffe said that so far as his review of the records showed, this was the first case of manic-depressive psychosis in a child of ten years that had ever been presented or reported at a meeting of this Society. He agreed with Dr. Gregory that such cases might readily be overlooked by the parents or physician, and that the symptoms might be attributed to malaria or constipation or various other bodily ailments.

Dr. William B. Noyes said it was rather difficult to definitely classify a case of this kind without a better understanding of the various gradations of mental depression or excitement associated with mental changes that were not uncommonly observed about the age of puberty. The exaggeration of the normal changes frequently observed in the child at that period of life resembled certain psychoses of later life. In some children, these changes were entirely physiological; in others they were slightly exaggerated, or again we might have the extreme type, as evidenced in this case, although the symptoms might not be so sharply defined. This, perhaps, might be accounted for by the fact that here we had a child of foreign parents, transplanted to a new environment, with poor surroundings and possibly influenced by the strain of over-study. Although the case presented by Dr. Gregory appeared to present clear-cut symptoms of manic-depressive insanity, in the opinion of many who frequently see pathological nervous and mental conditions during childhood, it was better explained as one of a series of mental variations, not so easily classified as Dr. Gregory stated.

Dr. L. Pierce Clark said that an accurate knowledge of the family history in a case of this character might prove a very important factor in making more definite the diagnosis here. Undoubtedly the case was rare in literature only. He had seen two similar cases, though less severe and definite. The case furnished a sad commentary upon our insufficient studies of the psychopathy of childhood. What we really ought to have was an intensive analysis of the development of physical and mental habits, the personality and character of childhood both in normal adjustments and abnormal adaptations to psychic shocks and crises. Often enough in the past all concerned had been quite content to put even as severe a mental depression as shown in Dr. Gregory's case into a class of physical ailments of childhood, but here a fairly defined psychotic disorder was too evident to be disproved in such a manner. He saw no good reason, however, why we should strive so hard to fit adult psychoses upon such young shoulders. Would it not be better to develop our types of psychoses of childhood upon the basis of symptom complexes as they presented themselves, and gradually make disease entities as they came into a well-rounded type largely independent of the nosological designations of adult psychoses? This had been one of the greatest contentions of Meyer, he believed, in his studies upon the nature of dementia præcox, and appeared to be the excellent purpose of Hoch's studies in the development of the shut-in and open personalities of the same group. No doubt psychopathic clinics in connection with the public schools, now being established in this country and abroad, would soon furnish us with a definite material and a better knowledge of just such cases as Dr. Gregory here presents.

Dr. A. A. Brill said he could recall two cases of this type, one a girl of about seven years whom he saw at the Vanderbilt Clinic and later referred to Dr. Gregory, and the other a boy of about ten whom he saw in Dr. Gregory's out-patient department. This boy was in a very excited and maniacal state; he constantly talked about blood,

which his mother attributed to the fact that he had seen some chickens slaughtered. The whole picture presented, besides the maniacal state, a certain phase of obsession of the compulsion neurosis type. The little girl, although evincing an unmistakable maniacal phase, also presented some hysterical features, and suffered besides from a rather severe gonorrheal infection. Dr. Brill asked whether there was any question of hysteria in these cases.

Dr. B. Onuf said that in cases of this kind the question of heredity was a very interesting one to follow up. His own observations had led him to believe that in psychoses of this character, particularly in the circular cases, we not infrequently found a history of manic-depressive heredity.

Dr. Gregory, in closing, replying to Dr. Brill, said he saw no grounds for calling this a case of hysteria. The child showed no evidences of that condition—no sensory disturbances nor hysterical stigmata. On the contrary, she showed all the symptoms of a manic-depressive psychosis. She was very active and restless. It was, of course, true that these conditions, especially the mild or excited types, were apt to be mistaken for hysteria. The speaker said he agreed with Dr. Noyes that we not infrequently saw children about this age with symptoms that were merely an exaggeration of the natural moods, but here we had a child with sharply defined symptoms coming on rather suddenly. The symptoms were those of a manic-depressive psychosis, and he did not see why we should not call it by that name. This girl, formerly very cheerful, meets with a disappointment and becomes depressed and remains in this stupid condition for several weeks. Normal children would not show the effects of such a disappointment for such a length of time, and upon analyzing the case we find psychic retardation and complaints of various ailments, in spite of the fact that she is perfectly healthy. She lacks initiative, and the symptoms are typical of manic-depressive insanity.

**Intraspinous Treatment (Swift-Ellis) for General Paresis.**—Dr. Jelliffe, in introducing a general discussion on this subject, said the year 1913 promised to be a memorable one in the history of general paresis. It was early in the year that Moore and Noguchi announced the finding of *Treponema pallidum* in the brains of paretics. It was demonstrated before this society at the March meeting. It was before this society, at the April meeting, that Drs. Swift and Ellis presented the details of their treatment by the intraspinous method; it was in the early part of this year that Drs. Nichol and Hough of Washington announced the successful cultivation of the treponema from the cerebrospinal fluid of cerebrospinal syphilis, which cultivation experiments were also successfully carried out by Noguchi and others. The findings of Moore and Noguchi were verified in various quarters; they were seen in the dead and living condition, and in the dead and living tissue; the latter first by Förster of Berlin, who obtained them from brain punctures of the living patients. Successful inoculation experiments on rabbits have been made with living brain tissue of paretics, and the results of these successful experiments have been passed on to other rabbits and the organism isolated, and the chain of evidence has practically been made complete. All this has been done within the twelve months preceding this date, and as a result the problem of the treatment of general paresis resolved itself down to the treatment of syphilis in a particular organ of the body, and how best can this be accomplished? Dr. Jelliffe said that his purpose in bringing this subject to the attention of this society again, after the lapse of so short a time as six months, has been determined by a number of reasons. In the first place, it has always seemed to him that perhaps the most important function of a society of this kind, consisting for the most part of active specialistic workers, should be to be on the firing line, as it were, of advance in that branch which the society represents; that subjects brought up for discussion, which have reached a fairly final state of solution, are already the property of most of the members of such a society; that when the final word has been said everybody knows it and therefore the material presented before ceases to have that quickening and stimulating value which would come from considerations of questions which are as yet in the state of being born. Therefore, the discussion which he had planned for the evening, and thanks for which he gave to those about to participate in it, was presented as a more or less nascent problem. If it was somewhat nebulous, if it contained more hopes and aspirations than definite records of positive acquisition, the position already outlined will be sufficient reason for bringing the matter up again. He had thought to narrow the discussion, more or less, to the treatment of paresis, because it seemed to him that here was an avenue in which a great work might possibly be accomplished, and that if attention were baldly and boldly directed toward a problem which in the past has been unconquerable, even an expression of our hope might be of value to the paretic. Certainly the valuable hints that were received at a former session of this society, in which the outlines of the Swift-Ellis method of treatment of syphilis of the nervous system were given, should not be laid aside while there is any possibility that a turning over of the same might result in profit. Even if it be granted that the time is as yet short, that the material as yet is but inconclusive, yet certainly in the experience of some of those about to discuss the paper of the evening, and in that of others who he hoped would discuss it, certain questions might arise which might be worthy of discussion. In the first place, what are some of the accidents which have accompanied spinal puncture, and the free utilization of the spinal canal? Have they been sufficiently serious to constitute a bar to its further use? Have they been sufficiently painful and disappointing to the patient to prevent their use? In other words, have we gained enough information concerning possibilities to enable us to outline a position? On the other hand, to what source must the advantages be attributed? What is the psychic factor of a new hope, of a new method of treatment? What reliance can be placed upon the unquestionable biological improvement? How does it coincide with the clinical manifestations? How long must one wait before a clinical observation must lag behind biological suggestions, and how far does the biological data enable one to extend one's hopes of positive results? Is the optimistic attitude a justifiable one, further than the general philosophical value of all optimistic attitudes in contradistinction to all pessimistic ones? These are the questions which he felt certain are of interest to others as well as himself and which he trusted would enter into the remarks of those about to speak.

Dr. William H. Hough, clinical pathologist to the Government Hospital for the Insane at Washington, D. C., said it had now been definitely established, chiefly through serological investigation and through the finding of the *Treponema pallidum* in the disease process by Noguchi and Moore, Levaditi, Foster, and others, that syphilis was an essential factor in the production of paresis, and although it was quite apparent that it was not the only factor entering into the etiology of the disease, yet our object of treatment, as in all infections, was to relieve the patient of the infectious organism. Therefore, any light that might be thrown upon the nature of the action of the infective virus might be of assistance in the treatment of the disease. This seemed especially important in the consideration of such a protean disease as syphilis. Concerning the treatment of paresis, the speaker said he would consider only the intraspinous injection of salvarsanized serum, as recommended by Drs. Swift and Ellis. We should bear in mind that we were dealing with a general constitutional disease which involved the nervous system especially, and not a disease confined to the brain alone. We were dealing with a disease process which involved a vital and inaccessible part of the body, the infective agent being the *Treponema pallidum*, probably in an especially virulent form. From his own experience with this method of treatment, which included three cases of paresis and one of cerebral lues, he could make no statements as to the final results, and his object in making this report was to show that they had already obtained results which could only be interpreted as evidence of the efficiency of the treatment for the inflammatory syphilitic process, but whether we could arrest the entire paretic process permanently was still undetermined, although from the clinical improvement obtained in some cases and from a theoretical standpoint, the outlook certainly seemed promising. The uniformity of the results obtained thus far indicated to him that it was the most efficient treatment for paresis that had thus far been recommended. The all-important point was to institute treatment early in the disease, and this we were now enabled to do with our improved method of diagnosis. This was perhaps more important in paresis than in tabes, inasmuch as a more vital and inaccessible part of the nervous system was affected. For this reason we naturally expected, and, judging from reports, were obtaining more favorable results in the latter disease than in the former. For syphilis of the central nervous system occurring in the early stage of the disease the speaker said he believed the intraspinous injections were to be recommended, although good results could be obtained in this condition by the proper use of mercury and salvarsan intravenously. Dr. Hough said the technique he had employed was the same as that originally recommended by Swift and Ellis, excepting that after the

first few injections he used 40 c.c. of a 50 per cent. serum instead of 30 c.c. of a 40 per cent. As to after-effects, he had observed none of any consequence, although there was sometimes a slight elevation of temperature, and in one case there was on several occasions a marked reduction of the pulse rate. The urine had remained normal in all cases. Thus far he had given 31 treatments. Dr. Hough then briefly reported three cases of paresis and one of cerebral syphilis in which he had employed this method of treatment. All of these patients were still under observation, and while he could make no statement as to the final results, he was convinced that it marked a distinct advance in the treatment of this hitherto almost invariably fatal disease. Judging from the effect that salvarsan had upon other similar spirochete diseases, especially yaws and other protozoan affections, and from the rapid advancement in chemotherapeutics as particularly indicated in the recent article by Ehrlich, he anticipated that in the near future the chemotherapy of syphilis would be so perfected as to prevent the development of the late nervous manifestations, which now showed such resistance to treatment.

Dr. H. S. Ogilvie, speaking for Dr. John A. Fordyce, who was detained at home by illness, reported the case of man who was taken to the Riverdale Hospital on June 12, 1913. He was extremely loquacious and made numerous unreasonable demands and suggestions. The following night he became very noisy and fought his attendants violently. He was disoriented, and his delusions, both visual and auditory, were very pronounced. He was fearful lest his attendants would kill him, and insisted that his brother and other members of his family were plotting against him. He boasted of his vast wealth and power. On June 19, he was transferred to Sandford Hall at Flushing, L. I., where his condition remained unchanged for the following three weeks. At times he was quiet and would take a small quantity of food, but for the most part he was extremely noisy and at times violent, and it was necessary to keep him almost constantly under the influence of hyoscine and morphine. On July 16, 1913, the patient was given an intraspinous injection of 30 c.c. of a 40 per cent. solution of salvarsanized serum, after the method of Swift and Ellis, the serum being prepared from blood taken from another patient one hour after a full dose of salvarsan. No change in his condition was noted during the following ten days. During this period it was found necessary to catheterize him daily. He was practically confined to bed, as otherwise it was extremely difficult to control him. His delusions and grandiose ideas still persisted. His memory had apparently slightly improved and orientation was better. On July 26, and again on August 4, the intraspinous injection was repeated. Following these treatments he was quieter, took his food well and slept better. His grandiose ideas were less marked and he seemed to have a better insight into his condition. His delusions of persecution, however, persisted, although not as marked as before. On August 14, about thirty minutes after an intraspinous injection, he had a mild convulsion. The nurse reported that his whole body suddenly became rigid and trembled for a few seconds, when he seemed to awaken with a start and looked about the room as though dazed. During the following week he steadily improved and sometimes it was almost impossible to detect any evidence of his psychosis. On August 22, he was given another intraspinous injection, which produced no reaction. The patient now seemed so much better that he was permitted to see his wife. He behaved well for the first fifteen or twenty minutes, but when the question of his leaving the sanatorium came up and he was told that he had better remain a few weeks longer he became very much excited and said that his family had no right to deprive him of his liberty. He agreed to return to the hospital, however, where he was now allowed to take long walks in the country and receive daily visits from his wife. He behaved well and showed but little evidence of his trouble. This was chiefly a tendency to be aggressive and sometimes unreasonable toward his attendants and physicians. On August 29, he received another intraspinous injection. As there had not been much change in his condition during the two previous weeks, it was decided to treat him with serum from his own blood. On September 4, he was given 0.45 gm. of salvarsan intravenously, and fifty minutes later about 50 c.c. of blood was taken from the opposite arm. From this a 40 per cent. serum was prepared, and on the following day he was treated intraspinously. He had no reaction from the salvarsan nor from the intraspinous treatment, and following this there was a very definite improvement in every way. The patient was brighter; he had a splendid insight into his condition; his grandiose ideas had practically entirely disappeared, and he spoke kindly of his brother and his wife. He was so well that he was permitted to go home for two days, and upon his return to the hospital he seemed to be normal in every way. His last treatment was on September 11, when he was again given salvarsan, followed by an intraspinous injection with a solution of his own serum.

Dr. H. A. Cotton of Trenton, N. J., presented a young man of eighteen who first came under his observation about April 29, 1912, with the history of convulsions, the first attack in December, 1911, the second the following April, and after that occurring with greater frequency. He was then attending school, but had to give up his studies on account of increasing irritability and dullness. The patient had a specific history, and a lumbar puncture, made in April, 1912, gave a positive reaction. He received several doses of salvarsan, and in April, 1913, after a consultation with Dr. Swift at the Rockefeller Institute, the intraspinous treatment with salvarsanized serum was commenced. The injections were repeated every two weeks up to June 2, and the patient, who was now living on a farm, was still under Dr. Cotton's observation. The cytological findings were now practically negative, the patient had gained thirty pounds in weight and showed no mental abnormalities at the present time. He still had stiff pupils and an occasional convulsion, but he was able to travel about by himself, and the improvement in his general condition had been very marked under this new method of treatment. In connection with this case, Dr. Cotton briefly reviewed the findings in eight additional cases of general paresis in which the intraspinous method of treatment had been employed by him. In two of these cases that came to autopsy, salvarsan was found in the ventricular fluid, which seemed to effectually answer the query whether the remedy was carried to the brain after the intraspinous injection, or was limited to the cord. Dr. Cotton said that while these reports were only preliminary, the results obtained thus far had convinced him that this method would prove efficient, providing it was undertaken in the early stages of the disease. In his early cases, the clinical symptoms had undoubtedly improved, together with the biological findings. This did not hold good in the late cases. He had, however, seen no bad effects follow the treatment in the late cases; he knew of no contraindications to the method, and expected to continue to employ it, especially in the early cases. He regarded it as a step in the right direction, and said that in the intraspinous method of treatment we had something that promised well in general paresis. We all understood, of course, that there was no possibility of curing these patients in the end stage. Just how far a case of paresis could go before the treatment had lost its effect on the process we could not say. We should not expect to regenerate a paretic brain, but the results thus far obtained led to the hope that we might be able to arrest the process during the early stages of the disease. The extent of recovery would depend on the amount of destruction of the brain that had already taken place. At the Trenton State Hospital the treatment had been resorted to in nine cases, including the juvenile case shown to-night. In all of these the pupils had remained stiff. The knee jerks had returned in one case. All the early cases had shown marked improvement, but in that connection we should take into consideration the normal proportion of remissions that were frequently seen in general paresis, as well as our own optimism in taking up a new method of treatment.

Dr. Burt Asper of the Sheppard & Enoch Pratt Hospital at Towson, Md., said there was practically nothing to add to this excellent presentation of this subject. At the institution with which he was connected they had injected ten cases of general paresis and one case of tabes by the intraspinous method, and their results closely paralleled those reported by Drs. Hough and Cotton. At the Sheppard Hospital they were fortunate in having had two early cases. One was a stonecutter, 39 years old, who gave a history of specific infection dating back 21 years, and who developed mental symptoms some two months before coming to the hospital. The case was unquestionably one of general paresis of the grandiose type, and the symptoms were typical. Following the first intraspinous injection the symptoms were aggravated, but after the second injection they moderated somewhat, and after the third one his mental condition cleared up entirely, although his physical signs remained unchanged. His memory defect had disappeared and he was permitted to return to his occupation, at which he was still engaged. Thus far he had shown no evidence of a re-

lapse. He was still under observation and treatment. The second early case was that of a cigarmaker, 45 years old, whose mental symptoms dated back six months. They were of the maniacal type and cleared up entirely under the intraspinous method of treatment. This patient was still under observation. Dr. Asper expressed the opinion that in the intraspinous injection of salvarsanized serum we had a very valuable method of treating general paresis —something which we had never had before.

Dr. Homer F. Swift of the Rockefeller Institute said that their experience with the treatment of general paresis by the intraspinous method was comparatively limited, and he would restrict himself to a few points in regard to the method. He was interested in the statement made by Dr. Cotton that after an intraspinous injection, the fluid taken from the ventricle of the patient was found to contain arsenic. This finding was in line with some work done in Dr. John Howland's clinic in Baltimore, where phthalein was introduced by lumbar puncture into the subarachnoid space and two hours later fluid obtained from the ventricles was shown to contain phthalein—50 per cent. of phthalein as compared with 100 per cent. in fluid obtained at the same time from lumbar puncture. In cases where the phthalein was introduced intravenously, however, there was no excretion into the fluid of either the ventricles or subarachnoid space. It is fair to assume, therefore, that arsenic or other drugs introduced into the spinal canal by means of lumbar puncture reach all points of the cerebrospinal system (at least the larger cavities) which are bathed by the cerebrospinal fluid. Uhlmann had shown that after intravenous injection arsenic is not present in the nervous tissue in the same proportion as in other parenchymatous organs. Dr. Swift said that the experience with the direct introduction of neosalvarsan into the spinal canal had shown that severe, unpleasant symptoms followed the use of the drug in this way. Both from a practical and experimental standpoint, the direct introduction of salvarsan into the cerebrospinal fluid is inadvisable. Contrary to the experience of some of those who preceded him, no catheterization has been necessary after the introduction of salvarsanized serum into the spinal canal except where the patient has previously suffered from retention. In most of the cases the bladder symptoms have improved following intraspinous injections. Dr. Swift said that he wished to call attention to the value of the titration method in doing the Wassermann test of the cerebrospinal fluid, and the importance of using a large quantity of the fluid. In doing the test, they employ up to five volumes as compared with blood serum and by using these larger quantities, the negative reactions become less numerous. The speaker also mentioned the value of making control tests, continuing either intraspinous or intravenous treatment until a negative reaction is obtained. In their own cases the improvement in the reaction usually goes hand in hand with clinical improvement. In some of the cases the fluid has remained negative for a year and a half after cessation of treatment, and there has been no advance in the tabetic symptoms. They have found that the pleocytosis is the first to disappear, the Wassermann is more likely to disappear next, and, finally, the globulin excess. In the four patients with paresis or taboparesis, the clinical improvement has not been very marked. One of the patients, however, is showing very distinct improvement. Patients with an initial, intensely strong Wassermann reaction in the cerebrospinal fluid usually require much more treatment than those with a weaker reaction. Of twenty-seven cases of tabes that are under treatment with the combined method, 50 per cent. show an entirely negative Wassermann in the fluid; 30 per cent. require the largest quantity of fluid to show a reaction. If tabes and general paralysis are similar diseases involving different portions of the central nervous system, then the results obtained in tabes certainly offer an encouraging outlook in paresis.

Dr. H. LeBaron Peters of Bridgeport, Conn., said he had at the present time six cases under treatment by the intraspinous injection method, of whom none had received more than four treatments. Two of these were cases of general paresis, two of tabes and two of cerebrospinal syphilis. The two paretics had shown considerable improvement from the biological point of view, and in one of them, particularly, there was a marked clearing of the mental condition. Of the others it was too early to speak definitely. No untoward symptoms following the treatments were noted except in the case of one of the tabetics. Here, however, there was for several hours after the treatments a marked exacerbation of lightning pains.

Dr. William M. Leszynsky said that it is not at all surprising that salvarsan should be found in the fluid in the lateral ventricles after injections into the spinal canal. During the epidemic of cerebrospinal meningitis several years ago, it was noted by the late Dr. H. P. Loomis that after argyrol was introduced into the spinal subarachnoid space, it was found at the autopsy distributed over the cerebral cortex.

# State Medical Licensing Boards.

## STATE BOARD EXAMINATION QUESTIONS.

State Board of Medical Examiners for the State of Texas.

*Austin, June 24-26, 1913.*

(*Continued from page 92.*)

### PATHOLOGY.

1. Name some of the tissue changes incidental to old age.
2. Give the pathology of acute lobar pneumonia.
3. Name some of the most essential lesions found in acquired syphilis: first, second, and third stages.
4. Name the chief findings in enteric fever.
5. Give the pathology of chronic interstitial pneumonia.
6. Give the pathology of hemorrhoids.
7. Give the morbid changes resulting from disease of the pituitary body.
8. What morbid condition is brought about from disease of the adrenals?
9. Name some of the pathological changes resulting from cerebral hemorrhage.
10. What is an opsonin?
11. What do you understand by productive inflammation?
12. What is the pathology of diabetes mellitus?

### OBSTETRICS.

1. Describe the changes that take place from the time the ovum is impregnated to the beginning of the second month.
2. Give the cause and mechanism of labor.
3. How would you manage a shoulder presentation?
4. Define ectopic gestation. Differentiate same from uterine pregnancy.
5. Give etiology and management of eclampsia.
6. (*a*) Define uterine inertia. (*b*) What do you understand by primary and secondary inertia? Describe them.
7. Give management of third stage of labor.
8. How would you do a podalic version?
9. Give management of puerperal stage.
10. Give etiology of hyperemesis and management of same.

### GYNECOLOGY.

1. Give the (*a*) clinical diagnosis, (*b*) microscopic diagnosis of carcinoma of the cervix uteri.
2. Differentiate between tubal pregnancy and ovarian cyst.
3. Name and describe the ligaments of the uterus and briefly outline an adequate operation for the correction of retroversion of the uterus.
4. What pathological conditions demand an hysterectomy?
5. Give a clinical description of a case of chronic pyosalpinx and outline an adequate surgical operation for relief of same.
6. Define Amenorrhea, dysmenorrhea, menorrhagia, metrorrhagia, and vicarious menstruation.
7. Describe clinically and pathologically three types of endometritis.
8. Describe the ovary (*a*) as to its anatomical relationships; (*b*) as to its physiological function.
9. A woman, aged 35, has an intermenstrual flow or discharge streaked with blood; mention four probable causes of same and make differential diagnosis with reference to malignant disease.
10. Give the etiology, pathology, and clinical diagnosis of chronic cystitis of woman.

## ANSWERS.

### PATHOLOGY.

1. *Physical changes characteristic of senility:* Cessation of growth; loss of weight; loss of stature; brittleness of bones; rigidity of cartilages; loss of elasticity of crystalline lens; feebleness and atrophy of muscles; grayness of hair; diminution of sexual activity and power;

arteriosclerosis, or other diseased conditions of the arteries; lessened capacity of chest; atrophy and degeneration of digestive glands, kidneys, and testicles or ovaries; slowed reflexes; impairment of the special senses.

2. *Lobar Pneumonia.* "(1) *Stage of engorgement.*—This is the stage of inflammatory hyperemia and edema, and it is characterized microscopically by overfullness and slight tortuosity of the pulmonary capillaries, and by swelling of the alveolar epithelium. The lung is of a dark red color; it is heavier and less crepitant than natural; it pits on pressure; and its cut surface yields a reddish, frothy, tenacious liquid.

(2) *Red hepatization.*—Here there is an exudation of liquor sanguinis and blood corpuscles. The exuded liquids coagulate within the alveoli and terminal bronchioles, the coagulum enclosing numerous white and a few red blood corpuscles. The alveolar epithelium is swollen and granular. The lung is now much heavier than in the preceding stage, and is increased in size, so as to be often marked by the ribs. It is quite solid; sinks in water, and cannot be artificially inflated. It is remarkably friable, breaking down with a soft granular fracture. The cut surface has a markedly granular appearance, seen especially when the tissue is torn, and due to the plugs of coagulated exudation-matter which fill the alveoli. The color is of a dark reddish-brown, often here and there passing into gray. This admixture with gray sometimes gives a marbled appearance. The pleura covering the solid lung always participates more or less in the inflammatory process. It is opaque, hyperemic, and coated with lymph.

(3) *Gray hepatization.*—"This stage is characterized by a continuance of the process of inflammatory cell-emigration, and by more marked changes in the epithelium. The white blood corpuscles continue to escape from the vessels, and the alveolar epithelium becomes more swollen and granular. The alveoli thus becomes more completely filled with young cell-forms, so that the fibrinous exudation is no longer visible as an independent material. The fibrinous exudation now disintegrates, and the young cells rapidly undergo fatty metamorphosis. The alveolar walls themselves, with few exceptions, remain throughout the process unaltered, although very occasionally, when this stage is unusually advanced, they may be found here and there partially destroyed. Owing to these changes, the reddish-brown color of the lung becomes altered to a grayish or yellowish white. The granular appearance is much less marked; the solid tissue is much softer and more pulpy in consistence, and a puriform liquid exudes from the cut surface of the organ. This stage, when advanced, has been termed "suppuration or purulent infiltration" of the lung. (Quain's *Dictionary of Medicine.*)

3. In the *first stage of syphilis,* the chancre is the important lesion.

*The second stage of syphilis* is characterized by: Sore throat, mucous patches; the skin lesions or syphilides, which are characterized: By not itching; by being of a coppery or raw ham color; by being painless; by polymorphism, macules, papules, pustules, etc., being present at the same time; by being generally symmetrical. In this stage may also appear: Iritis, periostitis, and alopecia.

The *third stage* is marked by: Anemia, gumma formation, periosteal nodes, headaches, endarteritis and various other diseases.

4. *Pathology of typhoid fever.*—"Principally inflammation of the lymphoid tissue of the lower portion of the ileum, with more or less catarrh throughout the bowels. Peyer's Patches—1st week.—Are swollen through infiltration of leucocytes, the surfaces raised and fawn-colored—the infiltration involves the submucous coat. The lesions are most numerous at the lower end of the ileum. 2nd week.—The surface becomes abraded; sloughs form which are often bile-stained. 3rd week.—Sloughs come away, leaving ulcerating surfaces. Typical typhoid ulcers are thus formed. A few solitary glands undergo the same process. At the end of the week the ulcers begin to granulate, but healing is usually slow. Mesenteric glands may undergo the same changes, but more often become swollen, red, and tender only, or break down into cheesy masses. Other organs.—Spleen and liver are enlarged; heart is soft and flabby. The voluntary muscles undergo granular degeneration; in fact, similar changes to those found after death from high temperature." (Wheeler and Jack.)

5. In *chronic interstitial pneumonia,* the affected lung is cirrhosed and shows marked development of fibrous tissue; there is also tuberculous involvement of the lung; the lung is much contracted.

6. *Pathology of hemorrhoids.*—"*External piles* are found at the margin of the anus, and are covered with skin. They consist of a small central vein in a varicose state, surrounded by a development of subcutaneous fibrocellular tissue, which latter is much more abundant than the vascular element; in fact, they practically consist of longitudinal folds of skin of a dark brown color radiating from the anus, and superficial to the sphincter."

"*Internal piles* consist of dilated veins held together by a certain amount of connective tissue, and covered by mucous membrane. At first they are quite soft and compressible, and easily emptied on pressure; but when they have existed for some time the connective tissue may be increased in amount, and arterial twigs are often found running into the mass. The condition is limited to the lower 2 inches of the bowel, and may present very varied appearances in different cases. Thus, there may be general dilatation of the veins in the submucous tissue without the formation of any distinct tumors. The mucous membrane is then of a deep claret color, somewhat thickened, and liable to protrude during defecation.....When distinct hemorrhoidal masses form, they may be of two types: (*a*) The *longitudinal or fleshy pile,* consisting of broad sessile masses, dusky in color, soft and compressible in consistency, and covered by mucous membrane, which, although thin and stretched, still remains smooth and shiny, like the skin of a black grape. ..... (*b*) The *globular or bleeding pile* is single or multiple, and as a rule somewhat pedunculated; the surface of the tumor is roughened and granular, like a strawberry, due to the existence of dilated capillaries. When, however, a portion of it has been repeatedly protruded, the exposed mucous membrane becomes hard, and practically converted into skin, and the columnar epithelium may be replaced by the squamous type. The hemorrhage may be abundant, and comes either from the dilated superficial capillaries, or occasionally from a central arterial twig." (Rose and Carless' *Surgery.*)

7. *Disease of the pituitary body* may result in:—Hypertrophy, gigantism, acromegaly, formation of tumors, infantilism and obesity.

8. *Disease of the adrenals* may produce Addison's disease.

9. *Cerebral hemorrhage.*—"Primary effects are tearing and compression of the brain-substance. If the patient does not immediately die, softening occurs. As a result of the staining by the retained hemoglobin the area is known as red softening. Shortly after the blood escapes it undergoes coagulation, forming a cerebral hematoma. This acts as a foreign body and sets up an inflammatory reaction, with more or less hyperplasia of the surrounding neuroglia. The fluid portion finally becomes absorbed, the corpuscles broken down, and the pigment liberated, which stains the walls of the cavity. Occasionally a cyst filled with a clear fluid may form. If all fluids are absorbed, the walls of the cavity may come in contact and a scar result. Other primary effects are distant ones in the form of paralysis, both motor and sensory, and generally on the side of the body opposite to the seat of the hemorrhage. Although there may be a considerable return of the lost faculties, yet in a majority of cases permanent damage is done. This is due to the secondary effects—the secondary degenerations. These are systemic, and follow the direction of the nerve impulses. The commonest degeneration is one of the pyramidal tracts. The optic tract and fibers from the temporosphenoidal area may also be involved. In the brain there is finally loss of nerve-cells, without destruction of the neurogliar fibers. As a result of traumatism, hemorrhages may take place in any part of the brain, with or without fracture of the skull. The hemorrhage may be found on the side of the head opposite to that where the blow was received." (McConnell's *Pathology.*)

10. *Opsonin* is a quality of serum, or something occurring in it, which makes a microorganism more susceptible to phagocytosis.

11. *Productive inflammation* is inflammation specially characterized by the formation of fibrous connective tissue.

12. *Pathology of diabetes mellitus.*—"The normal blood contains a fairly constant quantity of grape-sugar, 0.09-0.1 per cent. This proportion is not decreased by starvation, or increased by the ingestion of carbohydrates; but should the quantity of sugar in the blood increase, an appreciable amount of grape-sugar will appear in the urine. The sugar is derived to a great extent from carbohydrates in the food, to a smaller extent from the splitting up of albuminous bodies and possibly also from fat. The glucose and other sugars, thus formed from food in the digestive tract, pass through the portal vein into the liver; hence the portal vein during digestion may contain as much as 0.4 per cent. of sugar; while a small quantity of sugar may pass into the chylous vessels and thus reach the blood through the thoracic duct. It is generally be-

lieved that in the liver the sugar is converted into glycogen, and by most observers that the glycogen in the liver is changed again into sugar and passed gradually into the blood; but Pavy and others maintain that the liver absorbs the sugar and prevents it from passing into the circulation. It must further be remembered that the muscles also contain glycogen and that they contain more when large quantities of carbohydrates are taken as food and when the muscle rests, but less during starvation and during increased muscular exercise. It is generally held that the liver and muscles by converting the sugar into glycogen act as storehouses, and that the glycogen remains stored up to be again oxidized; fat may also be formed from the sugar; this also becomes oxidized later on." (Quain's *Dictionary of Medicine.*)

OBSTETRICS.

1. *Development of the fertilized ovum:* "(1) When the ovum is mature, two small cells are detached from the main body of cells; these are called polar globules. It was formerly supposed that these were associated with the disappearance of the germinal vesicle, but recent experiments have demonstrated that the germinal vesicle plays an active part in their formation. This can take place independently of fecundation. (2) The portion of the ovum remaining after the throwing off of the polar globules is called the 'female pronucleus.' (3) Fecundation is effected by the penetration of the head of one spermatozoon. This is called the 'male pronucleus.' (4) The male and female pronucleus coalesce. The ovum is now called the oösperm, or blastosphere. (5) The *segmentation* of the nucleus and vitellus, *i.e.* they both split into two masses, these into four, and so on until a large number of segments are formed: This is known as the morula, moriform body, or mulberry mass. (6) A clear fluid is secreted within the ovum, which presses these segments to the surface of the ovum, where they form a double layer of cells, differing somewhat in size. The outer and larger is termed the *epiblast* or *ectoderm*, and the inner and smaller the *hypoblast* or *endoderm*. Together they are known as the blastodermic vesicle. (7) There then appears upon the outside of the vitellus a small oval elevation, surrounded by a depression, which is called the *area germinativa*. (8) There appears in the area germinativa a small, dark line called the *primitive trace*. About this line will be grouped the various parts of the embryo, the rest of the ovum serving only as a covering and for nutriment. (9) A covering for this trace or embryo is now formed. Thus far the vitelline membrane has been sufficient. The embryonic line sinks into the center of the ovum, while the edges of the external blastodermic layer about the area close around it, inclosing it in a sac called the *amnion*. Between the amnion and the embryo, fluid at a later period is deposited; this constitutes the liquor amnii. The vitelline membrane then disappears." (Landis' *Obstetrics.*)

The changes during the period indicated in the question are thus summarized by Polak: "*First week.*—Segmentation of fertilized ovum to form morula while passing along oviduct to uterus. Cleavage cavity present, marking stage of blastula. Great increase in size. Cells of inner cell-mass rearranged to form entoderm and ectoderm. Embryonal area. Primitive streak. Amnion completed at fourth or fifth day. *Second week.*—Ovum in uterus imbedded to mucosa. Chorion and its villi. Vascularization of chorion and its villi. Heart indicated as two tubes. Oral pit. Gut tract partly separated from yolk sac. Medullary plate. Nasal areas. *Fourth week.*—Marked flexion of body. Cephalic flexures. Pancreas begun. Liver diverticulum divides. Bile ducts acquire lumina. Pulmonary anlage bifurcates, the two pouches being connected by a pedicle, the primitive trachea, with the pharynx. Anterior lobe of hypophysis begins. Optic vesicle stalked and transformed into optic cup. Limb buds apparent."

2. *Causes of labor:* Distention of the uterus after it has reached the physiological limit of its growth at the end of pregnancy; increased irritability of the muscle fibers of the uterus; increased reflex excitability of the parturition center in the lumbar enlargement of the spinal cord; extra distention of and pressure upon the cervix uteri; uterine contraction aided by the contraction of the abdominal muscles and the diaphragm.

The *mechanism of labor* differs in the different presentations. In a *vertex* presentation, the stages are: Flexion, descent, rotation, extension, and external rotation. In a *face* presentation, the stages are: Extension, descent, rotation, flexion, and external rotation. In a *breech* presentation, the stages are: Moulding, descent, rotation, and delivery of the breech: descent, rotation, and delivery of the shoulders; flexion, descent, rotation, and delivery of the head.

3. In cases of *shoulder presentation,* if seen before labor, version should be performed to correct the malpresentation; in case of impaction a cesarean section is indicated; sometimes decapitation or embryotomy has been performed, but a cesarean section is preferable. Cases of shoulder presentation have been known to terminate spontaneously, but it is not advisable to rely on this possibility.

4. *Ectopic pregnancy* is a pregnancy where the fetus is being developed outside of the uterine cavity. It may be interstitial, tubal, ovarian, or abdominal. *Symptoms of tubal pregnancy* will be signs of early pregnancy, hypogastric or inguinal pains, probable history of a previous sterility, probable expulsion of decidual membrane or shreds, softening of the cervix, enlargement of the uterus, presence of a distended tube, contractions of the wall of the gestation sac; if rupture occurs, there will be sudden, excruciating pains over the lower abdomen and on the affected side, shock, collapse, and symptoms of internal hemorrhage.

*Positive signs of pregnancy:* (1) Hearing the fetal heart sound; (2) active movement of the fetus; (3) ballottement; (4) outlining the fetus in whole or part by palpitation; and (5) the umbilical or funic souffle. *Doubtful signs of pregnancy:* (1) Progressive enlargement of the uterus; (2) Hegar's sign; (3) Braxton Hick's sign; (4) uterine murmur; (5) cessation of menstruation; (6) changes in the breasts; (7) discoloration of the vagina and cervix; (8) pigmentation and striæ; (9) morning sickness. *Subjective signs of pregnancy,* in the order of their appearance, are: Cessation of menstruation, morning sickness, increased frequency of urination, active fetal movements. *Objective signs of pregnancy,* in the order of their appearance, are: Softening of the cervix, changes in the mammary glands, discoloration of the vulva and vagina, pulsation in the vaginal vault, Hegar's sign, active fetal movements, ballottement, palpation of the fetus, intermittent uterine contractions, hearing the fetal heartbeat, rate of growth of the uterine tumor.

5. PUERPERAL ECLAMPSIA is an acute morbid condition occurring during pregnancy, labor, or the puerperal state, and is characterized by tonic and clonic convulsions, which affect first the voluntary and then the involuntary muscles; there is total loss of consciousness, which tends either to coma or to sleep, and the condition may terminate in recovery or death. *Etiology:* Uremia, albuminuria, imperfect elimination of carbon dioxide by the lungs, medicinal poisons, septic infection; predisposing causes are renal disease and imperfect elimination by the skin, bowels, and kidneys.

*Preventive treatment:* (1) The amount of nitrogenous food should be diminished to a minimum; (2) the production and absorption of poisonous materials in the intestines and body tissues should be limited and their elimination should be aided by improving the action of the bowels, the kidneys, the liver, the skin, and the lungs; (3) the source of the fetal metabolic products and the peripheral irritation in the uterus should, if necessary, be removed by evacuating that organ. The *curative treatment includes:* (1) Controlling the convulsions (by chloroform, veratrum, or chloral; (2) elimination of the poison or poisons which are presumed to cause the convulsions; (3) emptying the uterus under deep anesthesia, by some method that is rapid and that will cause as little injury to the woman as possible.

6. "*Inertia of the uterus* is the somewhat misleading term applied to weakness and inefficiency of the uterine action. It may be either primary or secondary, and it is of the greatest practical importance to distinguish between the two.

"*Primary inertia* is present from the beginning of labor, and is due to some inherent weakness of the uterus. Among conditions that are said to predispose to it are: Nervousness, frequently associated with primiparity, and particularly if the patient be very young or elderly; obliquity of the uterus; fullness of bladder or rectum; these conditions appear to affect the proper innervation of the uterus; previous disease of the uterine wall, or the presence of fibroid tumors; overdistention of the uterus, as in hydraminos or twins.

"*Secondary inertia* comes after the labor has been in progress normally for some time. It is more common in the second and third stages than in the first. It may be due to the same causes as primary inertia, but is more usually an indication of exhaustion of the uterine muscle after a prolonged effort to overcome some obstruction. Such obstruction may be due to the size, position, or presentation of the child, or to some fault in the hard or soft

passages. The all important point is to remember that to deliver the child with the uterus in this state is the worst possible treatment, as it is almost certain to be followed by severe post partum hemorrhage. A flabby, exhausted uterus is not a danger while the child remains inside it, but as soon as it is empty and the placenta begins to be separated the lack of proper retraction may readily permit a fatal bleeding." (Johnstone's *Midwifery.*)

7. In the *third stage of labor* the physician should seize the fundus of the uterus through the abdominal wall and knead and rub it until it contracts vigorously; then he should press it down in the direction of the axis of the pelvic inlet. This should last for about a quarter of an hour after the child is born. The placenta, after it is expressed, should be carefully taken by the physician so as to be sure that it is *all* expelled; at the same time care must be taken that no particle of membrane remains behind. Fluidextract of ergot may be administered. The *dangers* are: hemorrhage, retained placenta or clots or pieces of the membrane, and sepsis.

8. "*Internal version* is done by passing one hand into the uterus, seizing and bringing down one or both feet. The cervix must be sufficiently dilated to allow the hand to pass. It should be done as soon as possible after the membranes have ruptured. If there is only slight retraction of the uterus it may be done, by an expert operator, by deeply anesthetizing the patient, but one who has not had much experience of the operation should not attempt it. If the uterus is firmly retracted it should never be attempted. The patient may lie on her left side, or preferably on her back. The right hand may be used in all cases, but in some the left one does better. It depends on which way the child is lying. Use the hand which will most easily reach the front of the child. Thus, if its back is toward the mother's right side, use your right hand, and if the back is toward her left, the left hand; but if you are not accustomed to working with your left hand always use the right. The hands and arms should be thoroughly sterilized, and well washed in lysol solution. Pass the hand in a cone shape to dilate the cervix, if it is not sufficiently dilated already, and pass the hand on to the front of the child, rupturing the membranes, if they are unruptured. As much of the liquor amnii as possible should be retained in the uterus by damming it back with the wrist. If a contraction comes on, spread your hand flat on the front of the child and wait until the uterus relaxes. If you do not do this the pressure upon your closed hand will almost paralyze it, and may cause rupture of the uterine wall. Catch one or both feet, making sure it is a foot and not a hand. As soon as you get a foot, pull the leg down steadily into the vagina, if the uterus is quiescent, but if a contraction comes on, wait, spreading your hand out as before. The child's body usually rotates quite easily, unless the uterus is retracted round it. If version is attempted when the uterus is retracted, as in a transverse case, care must be taken to unhitch the shoulder from under Bandl's ring, if it is caught, but only an expert should undertake such a risky operation, and it should only be undertaken if there is a chance of saving the child's life. The final part of the delivery is carried out in exactly the same way as when the breech presents." (Jardine's *Delayed and Complicated Labor.*)

9. See HYGIENE, *Question* 3.

10. HYPEREMESIS GRAVIDARUM. *Causes:* Toxemia, reflex irritation, and neurosis. *Treatment:* If possible, remove the cause; pay attention to hygiene, diet; almost any drug can be tried, iodine, cerium, oxalate, bismuth, strychnine, ipecac, bromides, cocaine, have all been recommended; prompt induction of labor or even abortion may be necessary.

## GYNECOLOGY.

1. *Cancer of cervix:* Laceration and erosion are predisposing factors. It occurs most frequently between the ages of 35 and 50. The symptoms are hemorrhage, pain, and discharge. The diagnosis is made on the physical and microscopical examination. The cervix is hard and nodular, and the mucous membrane seems immovably fixed to the underlying tissue. These nodules break down, the entire cervix becomes ulcerated, or large cauliflower-like masses may fill the upper part of the vagina. The diseased tissue is friable and bleeds upon touch.

*Squamous celled cancer* is most likely to begin on the vaginal aspect of the cervix; it appears as an ulcer which erodes the cervix and consists of epithelial cones which invade the underlying tissues. *Columnar celled cancer* attacks the cervical canal; the endometrium here consists of spaces filled with columnar epithelium.

2.

| EXTRAUTERINE PREGNANCY. | OVARIAN CYST. |
|---|---|
| 1. Rapid and regular growth. | 1. Slower growth. |
| 2. Amenorrhea, followed by menorrhagia, with discharge of pieces of decidua. | 2. Menstruation not altered except occasionally in broad-ligament cysts. |
| 3. General symptoms of pregnancy present, changes in color of vagina, etc. | 3. Symptoms of pregnancy absent. |
| 4. Enlargement of the uterus. | 4. No enlargement of the uterus. |
| 5. Attacks of pain increasing in severity, finally culminating in a very severe attack, followed by shock and symptoms of internal hemorrage. | 5. In small cysts, no attacks of pain except from pressure. |
| 6. Pain is intermittent. | 6. The twisted pedicle may cause sudden and acute pain. |

—(From *Wells.*)

And see OBSTETRICS, *Question* 4.

3. The LIGAMENTS OF THE UTERUS are: (1) *Broad ligaments,* which extend outward on each side from the side of the uterus to the side of pelvis. (2) *Rectouterine ligaments,* which extend backward from the intraperitoneal portion of the cervix uteri to the peritoneal investment of the rectum. (3) *Round ligaments,* which extend from the uterus just below the Fallopian tubes, through the inguinal canal to the labia majora. (4) The *ovarian ligaments,* which extend from the superior part of the uterus, behind the Fallopian tubes, to the inner end of the ovary. (5) The *uterosacral ligaments,* which extend from the highest part of the cervix uteri to the sides of the sacrum, opposite the lower border of the sacroiliac synchondrosis.

*Alexander's operation:* "The pubic hair is shaved off and skin and vagina disinfected. The uterus is replaced and a glass stem with attached silk thread introduced into its cavity. A narrow Hodge pessary is placed in the vagina. Next, the patient's legs are extended. The operator stands on the side opposite to the liagment to be shortened; he locates the pubic spine, which is the leading landmark during the whole operation, and makes an incision from 1 to 3 inches in length through the skin over it, in the direction of the slit between the pillars of the external inguinal ring. Its length must be proportionate to the amount of adipose tissue present, but it should, if possible, not extend beyond the hairy portion of the mons Veneris, as then, after the hairs grow out again, the cicatrices will be entirely hidden. Next, the subcutaneous fat and the superficial fascia are divided in the same direction, exposing the glittering, satin-like pillars of the external ring, which is situated above and a little outward of the spine of the pubis and can be felt at the bottom of the wound. It is well to dissect the aponeurosis of the external oblique abdominal muscle, so as to see not only the pillars, but the intercolumnar fascia extending between them. During the incision several small arteries will be severed and must be clamped. In the external inguinal ring is seen a lump of fat which contains the ligament. This whole mass is grasped with an artery-forceps and drawn in the direction of the vulva. The genital branch of the lumbocrural nerve is seen as a fine white cord in front or to one side of the ligament. If it is in the way, it may be cut, but generally it suffices to push it aside. From the ligament extend a number of sinewy threads to the sides of the inguinal canal, which must be severed. Sometimes the peritoneum is invaginated and forms around the ligament a sheath, which must be stripped back with the nails of the fingers. When the isolated white tendinous ligament peels readily out from the canal, the wound is covered with iodoform gauze or sterile gauze; the operator takes his position on the other side and treats the second ligament in the same way. Before fastening the ligaments he should pull both forward and ascertain through the abdominal wall or the vagina, that the uterus is tilted forward. He should then slacken them from ¼ to ½ inch, in order to avoid undue strain on them and the formation of a hernia. They are fastened by passing three sutures of chromicized catgut through them and both pillars on each side, the last one comprising some of the tendinous tissue in front of the pubic bone. When the sutures have been tied, the superfluous

piece of the ligament, which will measure from 2 to 4 inches, is cut off. The superficial fascia is closed with running suture of plain catgut, and finally the skin wound is closed with two or three sutures of silkworm gut. The two wounds are dressed with one piece of iodoform gauze, guttapercha tissue, and plain gauze, kept in place by a double spica or straps of rubber adhesive plaster. At the end of a week the superficial sutures are removed. The patient should remain in bed three weeks." (Garrignes' *Gynecology.*)

4. The INDICATIONS FOR HYSTERECTOMY are given as follows: *For the abdominol operation:* All solid or cystic tumors of the uterus; cancer; uterine rupture during labor; certain conditions of puerperal sepsis; pregnancy complicated by pelvic deformity, cancer, or other serious obstacle to the passage of the child; uterine prolapse or inversion, and incidentally as a step in the removal of complicated suppurative conditions of the uterine appendages.

*For the vaginal operotion:* Bilateral suppurative conditions of the appendages; prolapse, cancer, pregnancy with cancer before the sixth month; certain septic conditions of the uterus; certain rare conditions which may require the ablation of a small movable uterus.

*For the combined operation:* Cancer, certain complicated fibroids; failure to secure hemostasis from below. (From *Reference Handbook of the Medical Sciences.*)

5. CHRONIC PYOSALPINX. *Symptoms:* A dragging sensation in the neighborhood of the affected tube; colicky pain, which is increased on exertion or even on standing; abdominal tenderness; menstrual disorders, as amenorrhea, metrorrhagia, dysmenorrhea, menorrhagia; dyspareunia; there may be septic symptoms and peritonitis; sterility generally ensues. On examination there will be found a fullness in Douglas' pouch and one or both lateral fornices; in these latter will be felt either the tubes, distorted and possibly adherent, or a sausage-shaped tumor, which is very painful; the uterus is retroverted or retroflexed, and may be bound down by adhesions; there may be an intermittent expulsion of pus, accompanied and preceded by a burning pelvic pain. There will be a leucocytosis. *The treatment* of the acute form consists in rest in bed, free purgation with Rochelle salts (5i every hour), hot vaginal douches, and hot applications to the abdomen. If the symptoms become more severe celiotomy is indicated. The chronic form may be treated during the menstrual period by rest in bed, free purgation, hot vaginal douches, local applications of iodine to the cervix and vaginal vaults, and glycerine tampons. If these measures fail removal of the tube and ovary and replacing the retroverted uterus, etc., are necessary.

6. *Amenorrhea* is absence of menstruation during the period of sexual activity. *Menorrhagio* is a condition characterized by excessive loss of blood during the menstrual periods. *Metrorrhagia* is a hemorrhage from the uterus at other than the menstrual periods. *Dysmenorrhea* is painful menstruation. *Vicarious menstruation* is the flow of blood from some organ (other than the uterus) recurring at the monthly periods and taking the place of menstruation. It may occur from the hemorrhoidal vessels, the lungs, the skin, under the nails, the mammary glands, ulcerated surfaces, and many other parts.

7. *Endometritis* is inflammation of the mucous membrane lining the uterus. There is no agreement as to classification, varieties, or terminology. The *acute form* is due to the introduction of septic bacteria, and is manifested by pain, constipation, irritability of bladder, rapid pulse, rise of temperature, and a profuse discharge. *Chronic endometritis* may accompany numerous pathological uterine conditions, but is generally due to gonorrhea. The symptoms are backache, headache, leucorrhea, profuse menstruation, and impairment of the general health.

*Pathology:* "In the *glandular* variety, there is both a hypertrophy and hyperplasia of the glands, the latter taking place mainly by lateral outgrowths of old glands; it is doubtful if new ones grow inward from the surface epithelium, as some state. Many of the glands have, on longitudinal section, a serrated appearance. In the *interstitial* variety, the interglandular connective tissue elements are most affected. The ordinary chronic changes in inflammation are found, the tendency to the formation of spindle-shaped cells and dense tissue being prominent. The glands may become pressed upon and obliterated. Sometimes small retention cysts are formed. These may sometimes cause projections of the surface. In *mixed* forms, the above changes are found in various proportions." (Webster's *Diseases of Women.*)

8. The *ovarics* are almond shaped, about 1½x¾x½ inch; they are attached to the posterior layer of the broad ligament, at the outer end of and a little below the Fallopian tube. Their *function* is to develop ova, and also an internal secretion.

9. Carcinoma, sarcoma fibroid, ectopic gestation, and abortion. In *malignont diseases*, there will be hemorrhage, offensive discharge, pain, and (later) cachexia.

10. CHRONIC CYSTITIS. *Etiology:* Microorganisms (including the gonococcus, staphylococcus, bacillus coli communis, and others), congestion, foreign bodies, rheumatism, gout, cold, traumatism, certain drugs. *Pathology:* The mucosa is thickened, exfoliated, ulcerated, gray in color, and may be covered with pus; villous projections may be observed, and phosphatic deposits are not uncommon. *Symptoms:* Frequent urination, with tenesmus and a burning sensation in the urethra; later on pain in the bladder, hematuria, and the urine contains pus and epithelial cells. Chills, fever, rapid pulse, and headache may also be present. A feeling of weight or pain in the pelvis is noticed.

(*To be concluded.*)

## BULLETIN OF APPROACHING EXAMINATIONS

| STATE | NAME AND ADDRESS OF SECRETARY | PLACE AND DATE OF NEXT EXAMINATION† |
|---|---|---|
| Alabama* | W. H. Sanders, Montgomery | Montgomery... |
| Arizona* | J. W. Thomas, Phoenix | Phoenix |
| Arkansas | F. T. Murphy, Brinkley | Little Rock |
| California* | C. B. Pinkham, 929 Butler Building, San Francisco | Sacramento.. |

*No reciprocity recognized by these States.

†Applicants should in every case write to the secretary for all the details regarding the examination in any particular State.

**Chronic Hypertrophy of the Lips.**—E. G. Graham Little reports the case of a young man, aged about 28, who had suffered from swollen lips for about three years. Both lips were greatly enlarged, covered with hyperemic mucous membrane, without noticeable fissures or increased glandular secretion. The degree of swelling varied within certain limits, increasing and decreasing from time to time, but never receding to normal limits of size. Owing to the persistent swelling the lips were everted, shiny, and rather dry than moist. There was no nasal discharge, but there were numerous carious teeth, especially in the front of the mouth. The gums were not swollen or tender. The Wassermann reaction was negative.—*Proceedings of the Royal Society of Medicine.*

### OCCUPATIONAL DISEASES.*

By W. GILMAN THOMPSON, M.D.,

NEW YORK.

I HAVE been for some years interested in the occupational diseases which have become, in the last few years in this country, a matter for intensive study, leading toward preventive legislation. The first American Congress on this subject was held in Chicago in 1910; the second in Atlantic City in 1912, in cooperation with the American Medical Association. These have been the chief public meetings, and any special study that has been made has been confined to a few states and a few individuals.

The United States Labor Bureau appointed Dr. Alice Hamilton to investigate the subject of lead poisoning in connection with the painter's trade. This trade covers 300,000 painters in various branches of the trade. As an instance of the frequency of poisoning in this trade, 18 per cent. of the workers were poisoned sufficiently to complain of the symptoms and seek treatment; and it was not known how many were less seriously poisoned. but as many as one-fourth had some evidences of poisoning symptoms. The Health Boards of Massachusetts and New Jersey also have investigated the subject of occupational disease, and the Illinois and New York State Factory Commissions have conducted valuable researches.

Poisoning by nitrate of mercury is acquired in the felt hat industry. The fur of rabbits is treated by nitrate of mercury, which seems to be the only substance that affects the cut fur in such a way that the fibers become interlaced, thus producing a firmer quality of felt. One hundred and two cases of chronic mercurial poisoning have been reported in the felt hat trade by Mrs. Lindon W. Bates; and in some of these cases a senile dementia was produced.

Dr. J. B. Andrews has made an investigation of phosphorus poisoning which has led to legislation controlling the match industry. In match factories he found a large series of cases in which either the upper or lower paw had been lost through phosphorus poisoning. In investigating the number of deaths from lead poisoning, in New York State alone in 1909-10, he found recorded 60 deaths, and in my own experience in hospital records 300 cases were gathered of sufficient gravity to seek hospital treatment. At the Cornell Medical Clinic an assistant, Dr. Kenney, has studied 25 cases in one winter. Some very good work has been done in the occupational diseases by Price and Graham Rogers of the New York State Factory Commission. In Massachusetts the State Board of Health has investigated through Dr. Hanson in the past five or six years the inhalation of dust in the dusty trades.

There seems to be a great lack of literature of the subject of the occupational diseases. At the present time in this country we should collect, as physicians, more accurate data. Legislation on the subject has been copied from the English law, by which four poisonous metal trade diseases, caisson disease and anthrax, are required to be reported. This latter is useless as regards this country, as cases of anthrax are so rare that many physicians have not seen one case. In England anthrax comes from sorting hides and rags. Legislators need intelligent cooperation from physicians in order to regulate hazardous trades in this country.

In the "blue beds," where lead workers produce lead carbonate, fermentation is produced by acetic acid, and sometimes by vegetable substances. Often the workmen go into the closed chamber without gloves or masks, their hands and clothes become covered with lead carbonate. Sometimes respirators are worn, but, as a rule, perfectly inadequate protection is found. In rooms where paints are mixed the room is often filled with lead dust, inhaled by the workmen. Workmen who make storage batteries have a particularly dangerous trade. The rooms are often dirty and the red lead paste invades everything. These men often chew tobacco and so swallow particles of lead and become poisoned. One rather exceptional case was that of a track walker: He carried torpedoes covered with lead, and also in the same pocket a quid of tobacco. In this way he acquired plumbism.

In the canning industry, where solder is much used, lead poisoning sometimes ensues.

In England, Sir Thomas Oliver initiated the study of occupational diseases. He found that in the pottery industry a very large number of women and children are employed, a large proportion of whom become seriously affected with lead poisoning. Articles of pottery to be glazed are dipped into lead nitrate solution. All kinds of materials have been tried, but potters prefer lead glaze for the work. Part of the risk is that the men dip their arms into the wet glaze composed of lead solution. In the ware cleaning room of some potteries a large revolving drum scours off the excess of lead glaze. The dust can be carried off by aspirating ducts which minimize the risk of lead dust. A man occupied in polishing porcelain ware may be protected by a respirator and the article polished is held inside a closet, so that the dust is not breathed by the workman. The employers are now interested in an overhead douche where the workmen can strip and wash off the lead particles, and put on clean clothes, so that the body is protected to a great extent from the hazard of lead poisoning. There are one hundred and fifty trades in which lead poisoning is a hazard.

*Abstract of an illustrated paper read at the two hundred and fifty-seventh meeting of the Practitioners' Society of New York, November 7, 1913.

Congressional legislation has placed the employment of white phosphorus under so prohibitive a tax that its further use will be impracticable. This is the only example of legislation of this kind. In the match industry a phosphorus paste is prepared and a traveler carrying thousands of match sticks dips them into the phosphorus, holding them till sufficiently dry to be removed. The fumes and handling of phosphorus are a hazardous condition. Many women and children are employed in this industry and the unhygienic rooms add to the risk of the workers. Child labor is well represented in the match industry, where girls are occupied in sorting matches, and when, as formerly, poisonous phosphorus was used, many cases of necrosis were reported.

A dramatic incident happened in the case of the investigation of Dr. Andrews. The passage of the legislation was blocked by a certain senator, who was suspected of sympathizing with the match industry. Dr. Andrews got permission to make an exhibit. The senator obstructed the motion, but Dr. Andrews produced his exhibit, which was a man who had lost his jaw by phosphorus poisoning. When the senator saw the man he turned pale and fled, and no more was heard of his opposition.

Arsenic constitutes a hazard in many industries, though its use has largely been given up in the manufacture of wall paper, artificial flowers, etc., and has been replaced by aniline dyes. Workmen in dyeing industries are not sufficiently protected. They wear poor overalls and dip their arms into vats containing various solutions, such as Paris green.

In the examination of caisson disease, Dr. F. L. Keays did a very important work as physician to the Pennsylvania tubes under the East River. He had the examination of all the workmen, of whom 10,000 were employed for several years. There were 3,692 cases of caisson disease and 20 deaths. The treatment of the workmen is now regulated by law. When a man comes out with the "bends" he is immediately recompressed in an air lock, so as to allow the nitrogen bubbles which he has absorbed, to escape more slowly. The workmen also have warm and dry clothing on coming out of the tubes.

In the glass cutting industry workmen require protection from the powdered emery used in cutting and polishing glass. Miners require protection in overhead drilling. The stream of dust and falling particles have to be directed away from the workman. Stone cutting needs the same protection. Granite dust is particularly irritating to the lungs, and the workers often have chronic rhinitis and bronchitis. Owners of textile and other factories are careless about dust and report that the girls get used to a chronic catarrhal condition, especially in the button industry, which evolves a large amount of irritating dust. The buttons are made from the inside of mussels obtained in the Mississippi River. The button is punched out and the refuse used for fertilizer. In the making of meerschaum pipes the dust sometimes produces pulmonary disease and bronchial catarrah. Rag sorting is a very dirty, unhealthy process, although the rags are treated beforehand. In jute picking the organic dust is particularly irritating to the lungs.

In the polishing of rubber shoes naphtha is used, and this leads to symptoms of pronounced anemia on the part of the workers. In metal tempering the men stand so near the furnace as to acquire affection of the eyes from the intense heat, and the fumes and steam are a hazard. In glass bottle blowing, which is now not so much done with the lungs as formerly, owing to the introduction of machinery, the glass blower is apt to suffer injuries of the skin of the hands from the hot tubes and may acquire emphysema. In paper mills, because of the chloride of lime used in the manufacture of paper and from the rag sorting and consequent dust, the workers often suffer poisoning from lime and dust.

In Vienna, Berlin, and nearly a dozen other foreign towns, there are now Museums of Safety; and in Milan there is a hospital containing one hundred and fifty beds with excellent laboratories and an Out Patient Department exclusively for the treatment of industrial diseases. In the museums all kinds of devices for securing the safety and health of the workmen are exhibited.

I want to impress on this meeting the importance of definite and cooperative investigation. In my clinic I use a special kind of history card for the reporting of industrial disease.

In connection with the subject of occupational disease a man who recently came for treatment suffered from an unusual condition. He was a motor man who was accustomed to refrain from emptying the bladder for a long time, and in this way the bladder became enormously distended. He also was accustomed to bolt his meals and thus his stomach was distended. This case can be classed as an occupational disease.

The subject of occupational disease calls for the cooperation of economists and philanthropists as well as legislators and physicians. Suitable legislation is bound to come.

61 West Forty-ninth Street.

## BERIBERI.*

### AN ADDITIONAL EXPERIENCE AT CULION. HOW CAN A KNOWLEDGE AS TO ITS PREVENTION BEST BE APPLIED FROM THE STANDPOINT OF STATE MEDICINE?

By VICTOR G. HEISER, M.D.,

MANILA.

DIRECTOR OF HEALTH FOR THE PHILIPPINE ISLANDS.

THE tremendous morbidity and mortality rate in the Orient due to beriberi warrants me, I believe, in bringing this disease to your attention once more.

In previous papers proof was offered of the intimate relationship that exists between polished rice, when used as a staple article of diet, and beriberi. Since these papers were written, medical literature has fairly teemed with additional evidence to support this relationship.

The recent International Congress of Medicine and Surgery held in London during August passed resolutions which substantially reiterated those adopted by this association in 1910 and 1912. It is indeed gratifying that similar action should come so quickly from the foregoing and also from other independent sources.

On account of the large number of persons involved, it was thought that it might prove of interest to report the following additional experience which was had with beriberi in the Philippines. In a previous paper read before this association in 1912 at Hongkong, among other instances cited was that of the Culion Leper Colony, in which beriberi completely disappeared after unpolished rice

*Read at the third biennial meeting of the Far Eastern Association of Tropical Medicine, held in Saigon, November 8-15, 1913.

was used exclusively, and the colony remained free from beriberi from March, 1910, to January, 1912; or, in other words, during the entire period during which unpolished rice was provided.

During the autumn of 1911 there was a great shortage in rice throughout the Orient and this led to much speculation which had for its object the controlling of all the available rice. The price was advanced in some instances 100 per cent. or more. The Philippine Government, in order to protect the people of the Philippines as much as possible from extortionate prices, successfully broke the corner in rice so far as the Philippines were concerned, and in a short time the cost was reduced to more normal figures. Unfortunately, however, in order to accomplish its purpose the government was compelled to purchase large quantities of polished rice and in order to dispose of it, large issues to the Culion Leper Colony were begun in November, 1911, and continued until February, 1912. During January, 1912, cases of beriberi began to occur among the inmates of the colony and the general mortality rate began to rise rapidly. At the beginning of February the use of polished rice was discontinued and the use of unpolished rice was resumed. A reduction in the number of new cases of beriberi soon took place. The following table will show at a glance the morbidity and mortality rates before polished rice was used, during the period it was used, and after it was discontinued:

| 1911. | Total Deaths. | Deaths from Beriberi. |
|---|---|---|
| October | 26 | 0 |
| November | 24 | 0 |
| December | 31 | 0 |
| 1912. | | |
| January | 35 | 2 |
| February | 86 | 36 |
| March | 82 | 60 |
| April | 25 | 3 |
| May | 29 | 6* |
| June | 38 | 2* |
| July | 22 | 1* |

*Cases admitted to the colony suffering from beriberi.

It will be noted that two months after the use of *polished* rice was begun cases of beriberi began to appear and that the maximum number was reached three months after its use began. It may also be seen that three months after the use of *unpolished* rice was begun beriberi had completely disappeared. Nor has there been any beriberi at Culion since that time among inmates who were subsisted by the government. From time to time there are, of course, persons admitted who are suffering from beriberi or occasionally there are inmates who purchase polished rice for themselves and sometimes beriberi occurs among them. All cases, however, regardless of their origin, are recorded in the foregoing table.

In the experience of Culion, then, we have an institution of over 3,000 inmates that prior to the use of unpolished rice in 1910 had an annual death rate of 201 per thousand from beriberi, which was reduced to zero during the period of 21 months that unpolished rice was used, and upon the use of polished rice being resumed beriberi returned and was directly responsible for a death rate of 157 per thousand per annum. When unpolished rice was substituted for polished rice beriberi again disappeared and has remained absent to date, or a period of 20 months.

With the exception of the very general scheme to educate the masses, no practical plan to reduce the occurrence of beriberi upon a large scale has as yet been put forward that has received universal support. With the overwhelming evidence now available that beriberi, in epidemic form at least, can be successfully eradicated among those who use rice as a staple article of diet, it seems strange that at least 100,000 deaths should continue to occur annually in the Orient from this disease. At this conference we should seriously ask ourselves whether everything possible is being done to put our knowledge into practical effect. In the Philippines education has been faithfully tried. Over half a million school children have been taught the contents of Health Bulletin No. 12, entitled "Beriberi and How to Prevent It," of which I submit a copy to each of you in order that you may judge for yourselves as to whether the subject is adequately presented. In Manila, articles have been published in the newspapers since 1910 at intervals of a few weeks in English, Spanish, and the vernacular. Public addresses on beriberi are frequently made.

The official statistics for Manila show the deaths from beriberi to have been as follows:

| Year. | Number of Deaths. |
|---|---|
| 1910 | 970 |
| 1911 | 1480 |
| 1912 | 1209 |
| 1913 | 980 |

From these figures it is apparent that after three years of faithful trial of the educational methods we are practically where we were in 1910. A review of the statistics of other oriental countries shows that much the same condition of affairs exists there.

In the past the writer has recommended that a definite standard as to what constitutes polished and unpolished rice should be adopted and that the amount of phosphorus pentoxide might be used as an index of the degree of polishing which the rice has undergone. There seems to be a very general agreement among workers in beribri that any rice which contains more than four-tenths of one per cent. of phosphorus pentoxide may be regarded as incapable of causing beriberi. A quite extensive practical experience with this standard in the Philippines has shown it to be very satisfactory. The accurate method for arriving at the amount of $P_2O_5$ is, of course, through chemistry, but we have found that for a rough test the method suggested by some writers, that the approximate degree of polishing could be roughly ascertained by the depth of the color when rice is stained with either methylene blue or iodine, is satisfactory. Briefly, any rice that stains deeply with Loeffler's methylene blue or Churchill's tincture of iodine contains less than 0.4 per cent. of $P_2O_5$ and a rice that stains only slightly contains more than 0.4 per cent. $P_2O_5$. By the use of this simple method a dealer could be reasonably certain, by applying the test himself, as to whether he was buying or selling polished or unpolished rice.

The writer has further recommended that probably the best way in which the very general use of unpolished rice could be brought about would be to

place a tax upon polished rice. This plan has many features to recommend it. In the first place, if adopted by general agreement by all the countries in the Orient it would in no way disturb the fiscal arrangements in any country because it would be in addition to any other tax. Second, it would leave polished rice available for those who could afford to pay for it, and among whom, on account of their better financial ability to purchase other foods in addition, it would cause no beriberi. Third, the owners or managers of rice mills would immediately adjust their process of manufacture so as to produce a rice that contained at least 0.4 per cent. of $P_2O_5$. Fourth, the small amount of rice which is polished by hand could be safely disregarded. Fifth, the tax would soon result in the discontinuance of the manufacture of polished rice and there would be no tax to collect. Sixth, in the few instances in which there would be a tax to collect it would be done economically and with the smallest amount of disturbance to business.

Briefly, the greatest obstacle toward bringing about the more general use of unpolished rice has been the fact that rice mill owners refuse to produce unpolished rice, probably fearing that by so doing they would be placed in an unfair position with competitors who had not adopted the manufacture of unpolished rice.

On account of the fact that the solution of the beriberi problem would probably save more human lives and at the same time be of greater economical advantage than any one health measure proposed in modern times, it is thought that this subject well merits the most serious consideration by the various governments concerned, and it is respectfully recommended that this congress urge upon the governments taking part to name a delegate or delegates who would have authority to discuss the matter and to draw up a practical working plan to bring about that desired result. As Singapore is probably the center of the greatest number of interests involved, it might be well to suggest that the convention of delegates be asked to meet there in conference.

## THE RELATION OF EXPERIMENTAL SYPHILIS TO EUGENICS.*

By HENRY J. NICHOLS, M.D.,

CAPTAIN, MEDICAL CORPS, U. S. ARMY.

(From the Department of Pathology, Army Medical School, Washington, D. C.)

SYPHILIS is generally conceded to be the worst of all the infectious diseases in relation to the welfare of the next generation. Taken the world over, the only other specific disease which can be compared to syphilis, in this respect, is gonorrhea; and it is doubtful if the evil consequences of gonorrhea, such as sterility in the prospective parents and blindness in the children, equal the sum total of damage which is traceable to the spirochetes of syphilis, in the way of miscarriage and of the flooding of the child's body with such dangerous and resistant parasites. This is not the place to rehearse the tragedies of conjugal and inherited syphilis; but the confidences of the physician's office bring out the terrible reality of syphilis as a family disease and the testimony of school teachers, of employers, of directors of homes for feeble-minded children and of hospitals for the insane is eloquent in regard to the handicap under which congenital syphilitics face life.

In the strict academic sense of a unit character bound up in the chromosomes of the parents' germinal protoplasm, syphilis is not hereditary for generations; although there are authentic cases on record of the mechanical transfer of the parasites of the disease to the third generation. However, from the practical viewpoint of the welfare of the immediate offspring, syphilis is worse than a detrimental unit character because the parasites are not limited to any one organ or tissue, but can and do permeate them all.

The dangers of the marriage of syphilitics have long been known and the medical profession has long insisted on safeguarding the health of prospective parents and that of their children by rules which covered the situation as far as existing knowledge permitted. Until recent years, however, our knowledge of syphilis has been far from satisfactory and our rules have frequently failed of their purpose. Within the past decade our knowledge of the disease has been greatly enlarged especially by experimental and laboratory studies, and we are now equipped with more efficient tests to determine the marriageability of persons who have had syphilis and are better prepared to prevent the advent of damaged successors.

Along with this increase of knowledge and partially dependent on it has developed the modern movement of eugenics, which is only a part of a larger movement for the control of nature and society for human welfare and happiness. The first essential of this movement is knowledge or science, for we cannot act with good effect if we are in the dark. The second essential is rightmindedness or the desire to use knowledge for human welfare. When evils are brought to light, right-minded persons feel an irresistible impulse to correct them and the eugenics movement along these lines is one of the most encouraging signs of the times. In the words of the most illustrious living exponent of the larger movement we may say that the eugenics movement is "a sure indication of the eternal forces of human growth, of the God-given impulse implanted in mankind to make a better race and a better earth."

As has already been pointed out, the great recent advances in our knowledge of syphilis have come from the laboratory rather than from the clinic. Experimental syphilis is still a young branch of syphilology and much work remains to be done, but certain facts have been established and experimental syphilis has a claim for consideration because its findings once established are more reliable than those of the clinic. One of the best examples of the superiority of the experimental and laboratory method over that of simple observation of the patient is seen in the recent downfall of Colles' so-called "law." It has long been taught as an outcome of clinical observation that an "apparently" healthy mother of a syphilitic child will not become infected by nursing or handling her child, because in bearing a syphilitic child she has become "immune" to the disease. It is usually true that the mother under such circumstances does not become infected, but as a result of experimental work and laboratory tests, we now know that she does not become infected, not because she is "immune," but because she herself has the disease, usually in a so-called "latent" form. That is, she is only "apparently" healthy and later on will pay toll to the hidden para-

*Read before the Eugenics Section of the American Association for the Study and Prevention of Infant Mortality, November 15, 1913, Washington, D. C.

sites. The same is true of Profeta's so-called "law" which relates to the "apparently" healthy child of a syphilitic mother. The child is really not immune and really has the disease and will suffer accordingly. There are many other aspects of the disease which can be thoroughly understood and intelligently handled only by the production of the disease in animals and by the study of it under the rigid conditions of scientific experiment.

*The possible affinity of Treponema pallidum for the reproductive organs.*—What is the explanation of the almost deadly certainty that a syphilitic husband will infect his wife and that some at least of their children will be born with the disease? As a result of recent experimental studies in syphilis, we know that the disease is a septicemia in its early stages. The virus is circulating in the blood and has been recovered in as high as 80 per cent. of cases in this period.[1] It would not be surprising, therefore, that in this period the virus should be transmitted in the marriage relation. But this is not the stage in which the damage is usually done; more often it is later in the disease, when the future father thinks he is cured, that marriage occurs and the disease is passed on. Experimental syphilis has something to say on this subject and undoubtedly will have more to say in the future.

It cannot be stated as an established fact that the *Treponema pallidum* has an especial affinity for the reproductive organs, but there are several evidences of this insidious possibility. The most fruitful part of experimental syphilis has followed the transmission of the disease to the rabbit and this field of work remained limited until it was discovered that the sexual organs are the best place for the multiplication of the parasites. It is a fact, also, that an intravenous injection in the rabbit results first and sometimes only in lesions of the scrotum and testicle. Such observations are suggestive to say the least. Along the same line of thought, Uhlenhuth has called attention to the fact that the virus of dourine, a sexual disease of the horse, multiplies best in the testicle in experimental inoculations of the rabbit, either direct or intravenous. Again, Neisser says that in infected monkeys the testicles are more highly inoculable than milk or bone marrow. These observations seem to indicate that infection of the reproductive organs is not merely a part of the general flooding of the body with the parasites, but that the parasites actually have an affinity for these tissues. If this is so we may be dealing with a character of the parasite which has been acquired in order to perpetuate itself, and if this is the case the disease becomes just so much harder to combat. The solution of this problem, which is a very practical one, can come only by the experimental method.

Neisser[2] has reviewed this subject up to 1911. Spirochetes have never been found in the seminal fluid by direct microscopical examination, but inoculation experiments have revealed their presence. Neisser himself failed to infect monkeys in seven trials with fresh seminal fluid from cases in various stages of the disease. Hoffman failed in three trials with fluid from cases of $2\frac{1}{2}$ months, 11 months and 18 months standing. Finger and Landsteiner were successful in two cases. In one the patient had had a syphilitic orchitis so that this case can be ruled out. In the other instance spermatic fluid was obtained from a case in the secondary stage by expression of the seminal vesicles and prostate; it was centrifuged and injection of the centrifugate into a monkey resulted in a definite syphilitic lesion. The fluid was apparently perfectly normal and contained active spermatozoa. This result is a distinct contribution to our knowledge of syphilis in relation to eugenics. It also raises the question if the male sexual element does not actually carry the virus. Since 1911 the only work recorded in this line has been done by Uhlenhuth and Mulzer,[3] who have confirmed Finger's observation in so far as relates to the infectiousness of the seminal fluid in the secondary stage. They obtained seminal fluid from an early case with relapse after salvarsan and successfully inoculated three rabbits. The entire fluid was used. Seminal fluid from the same case after treatment failed to infect the rabbit.

It will be seen from these experiments that the seminal fluid of secondary cases is infectious. We are still uncertain about the seminal fluid of later cases, but clinical suggestions are strong here and it remains for experimental syphilis to say the final word. We are also in the dark about the mechanism of infectiousness, whether the virus is in the fluids or in the male elements themselves. The entire subject of the relation of the spirochetes to the female reproductive organs is untouched. In the solution of these problems little headway is to be expected, except by the experimental method.

Uhlenhuth and Mulzer have also taken up the difficult subject of experimental hereditary syphilis by breeding syphilitic rabbits. The great practical difficulties of this subject are apparent, but Uhlenhuth and Mulzer have already had some success. They have shown that there is no immunity in young born from syphilitic females and that the young may be infected *in utero* by producing the disease in the mother. A continuation of this work will probably yield very valuable results. If known to our misguided friends who oppose the experimental method, this work will also probably provoke the usual protest. This protest can be met by one question which has never been satisfactorily answered by the "antis" and until it is so answered it must remain as a stumbling block. The question is, how many rabbits is one human child worth?

*The relations of syphilis to the family.*—The relations of syphilis to marriage and the fruits of marriage may be outlined as follows: (1) The husband has syphilis. He infects the wife and she infects the embryo and has a miscarriage or an infected child. This is probably the most usual occurrence, but as stated above, it is possible in some cases that the father infects the ovum and that the mother is secondarily infected. (2) The husband has syphilis. He infects the ovum without infection of the mother. This is very rare, if indeed it is possible. (3) The wife has syphilis and infects the child *in utero;* the husband may be infected or not. (4) The wife is infected after conception and infects the child. In any case the result seems to be the same, the child is infected and suffers accordingly. It may be said that this outline should also include the more cheerful statement that either the father or mother may have syphilis and the child may be healthy. This may be true of the later children, but in a given case any such statement, unless backed up by the results of modern methods of examination, should be heard with scepticism. If a child is born to syphilitic parents and is not all broken out with sores on the skin, it is no sign that the child is healthy. The evil consequence of syphilis may not become evident for years afterward, and who has followed these "apparently"

healthy children for a sufficient length of time to speak with certainty of the clinical results? The only sure way is to use the laboratory tests available at present and the more they are used the more widespread the disease appears in the family. We frequently hear a syphilitic father say that his wife and children are healthy, but on examination we rarely fail to find evidence of the disease in the wife and in one or more of the children.

*The fitness of persons who have been infected for marriage.*—When is a person who has had syphilis fit to marry? In other words, when is syphilis cured? If either a man or woman still has syphilis we cannot safely give consent to marriage because there is a distinct risk in either case that the offspring will be infected. We cannot say that this will always happen, much less can we say that it will not happen. The chances are all in favor of its occurrence. Under the older rules, if a syphilitic had had more or less continuous treatment for one or two years and had shown no external symptoms for two or three years more, he was allowed to marry. It has been a great disappointment to find that a large number of such cases were not really cured and that they were not really fit for marriage. In fact, in the light of our modern tests for the presence of the disease, we have reason to believe that the majority of cases treated in the most approved way by mercury and potassium iodide were not really cured.' The disappointment over the failure of salvarsan to produce permanent effects in a small number of doses does not compare with the disappointment over the failure of our historical remedy, mercury, even when given for years to really cure the disease in the majority of cases.

At present we have four tests which have been contributed by experimental and laboratory work for the detection of the disease. These tests cannot safely be disregarded in determining the marriageability of persons who have had syphilis. These are as follows: (1) A series of Wassermann reactions. (2) The provocative Wassermann reaction. (3) The luetin reaction. (4) Examination of the cerebrospinal fluid. If any of these tests are positive, I believe that consent should not be given to marriage, because a positive result in any one of these tests, according to our present knowledge, indicates the presence of living parasites. In regard to the Wassermann reaction there is a tendency on the part of some clinicians to regard a positive result in late cases simply as an evidence of past infection, like the persistence of the Widal reaction after typhoid. In my opinion this is an entirely mistaken view and one full of danger. Everything we know about this reaction indicates that it is a symptom of the disease and it should be regarded as such. It is not strange that the other more comfortable view should be held, because, unless we hold such a view, we are compelled to admit that the older methods of treatment failed to cure in a majority of cases and even with salvarsan we are compelled to admit that some cases are practically incurable. But it is the duty of scientific medicine to seek and to state the truth and while the clinician in daily touch with the hopes and fears of the patient may be inclined to take the easiest route, it is the duty of the laboratory to stand by the facts as it knows them.

It is not necessary to enter into a detailed discussion of these tests here, but they should be used to supplement each other. I have compared the results of the first three tests in a series of late cases in the following table:

| | Wassermann Reaction | Provocative Wassermann Reaction | Luetin Reaction |
|---|---|---|---|
| 1 | – | + | + |
| 2 | – | + | – |
| 3 | – | + | – |
| 4 | – | + | – |
| 5 | – | + | – |
| 6 | – | + | – |
| 7 | – | + | – |
| 8 | – | + | – |
| 9 | – | – | + |
| 10 | – | – | + |
| 11 | – | – | + |
| 12 | – | – | + |

It is evident that we cannot safely rely on a single test; we must use all the means at our disposal. We must insist on a clean bill throughout if practical advance is to be made in eugenics. The standard here outlined is a severe one and many candidates will fail to measure up to it, but in view of the nature of the disease as already outlined, it seems to me the only safe standard. The requirement of an examination of the reproductive fluid is probably an impracticable measure, but it is not out of the bounds of possibility.

On the other hand it would be a great mistake to imagine that syphilitics are doomed because we find evidence of a hidden infection in so many cases. We have good reason to believe that a majority of the human race have tuberculosis at some time of life and in most cases without even knowing it, and syphilis in many respects is no worse than tuberculosis. In addition we have means of treatment. We can control the disease even if we cannot thoroughly eradicate it in late cases. Many syphilitics do the hardest kind of physical and mental work and are fit for all the activities of a useful citizen, with the one exception of the perpetuation of the race. For this function they should be made to qualify. In my experience most men, under these circumstances, are right minded. They are not willing to experiment with human flesh and blood. They are willing to forego marriage, for the time, and entirely, if necessary. Of course there are others who are not so mindful of duty and they should be forced into the same position by the combined efforts of parents, physicians, clergymen and public opinion as seen in the eugenics movement of to-day.

## REPORT OF CASES OF AMEBIC DYSENTERY TREATED WITH EMETINE.*

By JEROME WAGNER, M.D.,

NEW YORK.

THOUGH there is no doubt that heroic doses of ipecacuanha administered in bulk has greatly lowered the death rate of amebic dysentery, it is far from an ideal method of treatment, aside from the fact of its many failures. Dr. Leonard Rogers, who has performed noble service in India in combating this disease, is responsible for the use of emetine, the active principle of ipecacuanha, in the treatment of dysentery due to *Amœba histolytica*. Vedder has shown that emetine in dilutions of 1 to 100,000 killed the ameba in broth culture. At present there are still doubts as to the purity of these

*From the Clinic of Professor Jerome M. Lynch, New York Polyclinic Medical School and Hospital.

cultures, consequently Rogers determined to test the efficacy of emetine on the amebas as they exist in the stool. He found that placing mucus containing numerous active amebas in a physiological saline solution of emetine hydrochloride resulted in the killing of the amebas and in an instantly altered microscopical appearance, the strength of the emetine solution being 1 to 10,000. A solution of 1 to 100,000 resulted in death to the amebas within a few minutes. The first opportunity of testing the worth of emetine in the human subject came when a case presented itself where ipecacuanha could not be administered by mouth, and the results of the use of the drug were most gratifying. In his preliminary report Rogers cites three cases, one of acute hemorrhagic dysentery, one of chronic dysentery and one acute. In each case the drug effected a cure, whereas ipecacuanha had failed.[1] In these cases blood disappeared from the stools as early as the second day, and formed feces appeared. A later report by Rogers mentions twelve cases in which the drug had been used. This series of cases included all varieties and stages of amebic dysentery and its sequela, liver abscess. As Rogers states,[2] he had previously shown that in the vast majority of cases of liver abscess the pus in the liver was sterile, containing only the *Amœba histolytica* (85 per cent. of cases). The cases of plain amebic dysentery he treated with hypodermic injections of emetine hydrochloride, though at first the hydrobromide was used, but was found to be too insoluble, the dosage varying from injections of one-third grain to one-half grain twice a day, though at times as much as two-thirds grain was given at a dose. In fact, as much as one grain has been administered subcutaneously. In this series two of the cases had abscesses of the liver and the third a splenic abscess. In the first case the pus of the liver abscess was aspirated and quinine injected, but this resulted in failure. The emetine was then resorted to. Eight ounces of pus were aspirated and one grain of emetine in two ounces of sterile salt solution injected into the cavity; cure resulted. In the other case of liver abscess, in addition to the injection of the emetine into the cavity, one-half grain of emetine was injected subcutaneously for four successive mornings. An abscess of the spleen was similarly treated and cured. In none of the cases did nausea or vomiting follow the use of the drug, regardless of the dosage; though one-third of a grain of the salt, emetine hydrochloride, is equivalent to thirty grains of ipecacuanha. Two cases of persistent bloody diarrhea were also treated with emetine, but without result. Subsequently these proved to be other than amebic dysentery. From this fact Rogers assumes that it is only in dysenteries of the amebic type that emetine is effective. To sustain his argument that emetine is specific in amebic dysentery, he claims that he lost one-third of his cases treated with ipecacuanha in doses ranging from thirty to sixty grains a day and one-quarter of the cases left the hospital uncured. He finds that the emetine may be given by mouth in one-third grain doses, providing that the stomach is empty three hours before administration and kept empty for three hours following. In these cases no nausea or vomiting has resulted. It might be interesting to peruse a table that Rogers has prepared showing the relative action of emetine hydrochloride and ipecacuanha. The table covers thirty cases treated with the latter and twenty-five with the former.[3]

| | Died | | | Discharged otherwise | | |
|---|---|---|---|---|---|---|
| | In 3 days. | After 3 days. | Of other disease | Very bad. | Not cured. | Cured. | Total. |
| Ipecac | 4 | 7 | 2 | 2 | 4 | 13 | 30 |
| Emetine salts | .. | .. | .. | .. | .. | 21 | 25 |

The two cases treated with emetine that died of other causes can not in fairness be classified as failures, while the other two cases treated with emetine who died, were moribund at the time of admission. So it may be said that all the cases treated with emetine were successful. In those cases dying from other causes, the ameba was not found in the bowel post-mortem. With ipecac the average stay in the hospital was 16.4 days, with emetine 7.2 days. The stools became normal on an average of 11.4 days with ipecac, while with emetine they assumed their normal character in 2.35 days. The average number of grains of ipecac required was 406, with emetine two grains of the drug sufficed, the equivalent of 180 grains of ipecac. In two to four days all blood and mucus disappeared, while in acute hepatitis the pain disappeared in twenty-four hours. The temperature was reduced within a few days. In one case Rogers introduced one-half grain of emetine hydrochloride intravenously in 5 c.c. of saline with good results as to action. From this brief survey of the work of Rogers it can readily be seen that the active principle of ipecacuanha must be of undoubted value, and only time is necessary to render proof.

Allen[4] reports two cases of amebic dysentery treated with soluble salts of emetine, in one of which enormous doses of the drug were required. In this case the hydrobromide solution was first used, supposedly, but response came only after the hydrochloride was used in a dose of four grains. This dose caused nausea and vomiting. Lyons[5] reports six cases in which emetine hydrochloride was used with successful results in five, the sixth dying. In the five cases the stools became normal in nine days. Thompson[6] reports seven cases of cure after the use of emetine, one being a case of acute hepatitis. He states, further, that he has so treated one hundred and fifty cases, in some of whom the drug had no effect. This he explains by stating that in all probability they were a dysentery of the bacillary type. In these cases the emetine had no effect. The important item, however, is that of the dysenteries, 85 per cent. are of amebic origin.

There have been other isolated cases reported where emetine has cured an amebic dysentery.

No mass of evidence has ever been presented in so acceptable form, relating to the specificity of a drug in dysentery. Though Wadhams and Hill report three cases of amebic dysentery in whom the ameba disappeared after treatment with neosalvarsan, no further record is at hand.

The first case of amebic dysentery in America was reported by Osler in 1890. Since then the presence of this disease in our community is more or less a recognized fact. Ipecac has had its advocates and its opponents. Phenomenal success has never attended its use in this country, particularly when the cases are not under hospital control. At our clinic in the New York Polyclinic Hospital we have seen over one hundred cases in the past twelve years. While in most of these cases the diarrheal symptoms were severe, in only a small percentage was hospital retention necessary, and no moribund case has ever come under our observation. In all our cases the diagnosis was made only after the

finding of the *Amœba histolytica* in the stools, although we were always able to recognize the typical ulcers in the lower bowel.

In the cases reported below the treatment was ambulatory, the patient returning to the hospital each day for examination and treatment. In the first case the buttocks were used as the site of injection; but in the others, we used the fleshy part of the arms. We used one-half grain tablets of emetine hydrochloride dissolved in ten to fifteen minims of saline solution. In these cases we endeavored to give the patients total doses of three and one-half grains in daily fractions, thus consuming seven days in the treatment of a case. Protoscopic examinations were made as frequently as was possible, and microscopical examinations of the stools were also made at each opportunity. These examinations were made on a warm stage, and the material used was obtained from the surface of the ulcers in the bowel. When ulcers were no longer present mucus from the bowel was utilized. At times it was necessary to give the patients salts by mouth in order to obtain good material for examination.

From the study of the cases which have come under our observation, and which we are reporting in detail, we find that the average number of stools per diem, before treatment was instituted, was twelve to fifteen. On an average of one and two-thirds days after the initial injection the number of stools dropped to one, or at the most two, in twenty-four hours. At the end of a series of seven injections the stools numbered but one a day, and continue so to the present time. In all the cases the stools were fluid and freely mixed with blood and mucus before the first injection. In two of the cases the blood and mucus disappeared from the stools twenty-four hours after the first treatment, while in the third case the stools were free from blood and mucus on the third day after the first dose of emetine hydrochloride. This was the first time in years, the patient said, that his stools did not contain blood and mucus. On an average of three days after treatment had started, the stools became formed. In no case was the *Amœba histolytica* found after the first twenty-four hours. It required, on an average, two days to relieve the patients of all tenesmus, in two of whom this symptom was very severe at the time they first came under observation. In all cases following the first injection the patients felt very much better according to their own statements, and in each case there was great improvement in the appearance of the rectal mucosa, as revealed by proctoscopic examination three days after the first injection; while at the end of a week little sign of the ulcers remained, however numerous at the first examination. At the end of two weeks, with the exception of a slight anemia, the mucous membrane of the lower bowel was absolutely normal, and even the anemia had disappeared at the end of three weeks' time. One month after the patients came under observation a protoscopic examination showed a perfectly healthy mucous membrane in the lower bowel. In all cases the patients felt better, generally, reported gain in weight, and ability to indulge themselves in varieties of food. None of the cases receiving hypodermic injections of emetine ever vomited following the injection, nor were they even nauseated. The site of injection never developed any pathological condition. In but one case was a blood count made, as reported hereafter.

Case 1.—No. 240. P. M. Age 42. Male. Married. Occupation—Bottle Washer. Family History, Negative. Past History, Never ill before. Non-alcoholic. No tobacco. Venereal denied. Present condition. Dates back ten years when patient had his first diarrhea. The stools at this time were watery and had a foul odor. One week later noticed blood and mucus in stools. At first the blood was dark but later assumed a lighter hue. The stools now became very numerous, numbering twelve to fourteen a day; and associated with each movement there were severe griping pains in the abdomen and a bearing down sensation in the rectum. He went to a hospital in this city where he remained for two weeks and was discharged as cured at the end of this time. He said the diagnosis of dysentery was made. For two years he was free from all trouble, then a similar attack occurred, more severe than the first. The patient went to a hospital in this city, where he was confined for two months, at the end of which time he was again discharged as cured. Two years later he had another attack, which necessitated his confinement in a hospital for three months. Since then he has been free, until three months ago, when the patient was again attacked with diarrhea. The bowel movements numbered fifteen to twenty a day, consisting mostly of blood and mucus. Though he had no abdominal pains between movements, he suffered severe tenesmus with and immediately following each movement A severe headache was almost constant. In the past three months he had lost thirty pounds in weight.

*Physical Examination:* Revealed a poorly nourished individual, evidencing loss in weight; dirty, yellow complexion, with appearance of a profound anemia.

*Proctoscopic Examination:* Showed typical amebic ulcers in rectum. There was a large amount of blood and mucus in the canal from which emanated a characteristic foul odor. A specimen of this mucus was examined microscopically by Dr. Jeffries (Pathologist of Polyclinic Hospital) and the *Amœba histolytica* was found. *Treatment:* On May 14, two hypodermics of emetine hydrochloride were administered, one into each buttock. The dose was one-half grain. The following day this dose was repeated. May 15. On this day the patient said he felt better inasmuch as his bowels had moved but twice in the previous twenty-four hours instead of fifteen times, and in addition both movements were free from blood. The odor of the movements was still foul. On May 16, the following day, the patient reported but two bowel movements for the twenty-four hours, of a pea-soup consistency with but little odor. He had been absolutely free from all pain of any kind. A proctoscopic examination was made this day and showed a marked improvement over the previous existing conditions in the rectum. There was very little bloody mucus in the bowel. Another one-half grain dose of emetin was administered this day. Patient returned three days later, May 19, and was again proctoscoped. At this examination very few ulcerations were left in the rectum and the mucous membrane had a normal appearance. His stools were now formed, and for three days past his bowels had moved but once a day. On the 20th of May another half grain of emetin was given by hypo. Patient reported one movement in twenty-four hours, well formed and free from blood. No pain had accompanied the movements the previous week and the patient had gained one pound in weight. On May 24 a proctoscopic examination revealed but two ulcers in the lumen of the bowel while the patient reported regular daily formed movements. On June 3, patient came for treatment, reporting three loose movements after a glass of beer on June 1. On June 6, patient was again examined with the proctoscope, and showed a perfectly normal mucosa, with no signs of any ulceration, no mucus in stools or any amebæ in any of the excreta. Stools were now hard and well formed. On July 11, patient returned for observation and reported that he had some diarrhea after drinking beer or eating sour food. Was given five grains of ammonium bromide and ten grains of sodium bromide *t.i.d.* On the following day patient reported cessation of diarrhea and since then there has been no recurrence. One month later patient was still free of all trouble, regardless of what he ate or drank.

This was the first case in which we had an opportunity to test the efficacy of emetine as a specific in an amebic case. For this purpose the case was an ideal one. Typical ulcers were present in the bowel, the amebas were found and the patient was having from fiteen to twenty movements a day. The above

history describes most graphically the effect of the administration of the emetine. Though we have no means of knowing, we might make bold and assert that in all probabilities the patient was not cured of his ulcers in the previous attacks, notwithstanding a two months' confinement in a hospital. As is well known in amebic disentery, there are periods of rest where the patient has no diarrhea; and, in a small percentage of cases, there are even intervals of constipation. And although we have at present no means of knowing whether the patient will now remain free of his infection, the immediate action of the drug must be described as nothing short of most marvelous and gratifying. Our next case might be said to have been of even greater severity. The history is as follows.

Case II.—No. 279. W. P. Age, 33. Single. Shoemaker. U. S. *Family History:* Negative. *Past History:* Diphtheria at thirteen. Malaria and dysentery in Philippines in 1899 (14 years ago). Chancroids in 1901. (Sixteen sores.) Moderate drinker and smoker. General diet. *Present Condition:* Dates back to 1899 when patient contracted dysentery in the Philippine Islands. At that time had twenty to thirty daily movements with severe tenesmus. Was in the hospital for two months and although at the time of his discharge he was improved, he still had three or four soft movements each day, occasionally passing blood. This condition had persisted for all these years and for the past six months he had had at least six movements a day with passage of blood and mucus. Occasionally he had severe tenesmus and complained of great weakness. He was at least thirty pounds under his normal weight.

*Physical Examination:* The patient was extremely thin and sallow. The spleen was enlarged though there had been no malarial attacks in seven years.

*Proctoscopic Examination:* The entire mucous membrane of the lower bowel was thickened and edematous and there were numerous small and coalescel ulcers surrounded by an area of swollen white tissue. Temperature 99.6°, pulse 90, resp. 18. A microscopical examination of the mucus obtained from the surface of the ulcers revealed the presence of the *Amœba histolytica*. Treatment was instituted on June 27, one-half grain of emetine being injected into the subcutaneous tissue of the right arm. This was repeated on the following day, the left arm being used. There had been no improvement. This dose was repeated on June 29 and 30, and on the last occasion patient reported but one movement for the preceeding twenty-four hours, stating further that for the first time in years his stool seemed to be entirely free from blood. The movement was a semi-solid formed one. On July 1, the report was four stools, watery with traces of blood. Again one-half grain emetine was given by hypo. On the following day he reported three stools, soft, but no pain accompanying the movement or blood in the stools. One-half grain emetine was injected. July 3, the following day, was exceedingly hot and the patient felt very much depressed, consequently no emetine was given this day; there had been two soft passages in the past twenty-four hours. July 4, two movements, no pain. July 5, one movement, slight abdominal pain, no blood in feces. July 6 and 7, one stool, well formed, no blood or mucus. One-half grain emetine injected. On July 7, 8, and 9, there was one normal movement each day, without concurrent symptoms. On the 9th, one-half grain of emetine was iniected. On July 11, the patient returned for examination. His appearance was greatly improved, the pallor was not nearly so marked, his appetite was better and he was having one normal movement each day. A blood count was taken and showed 4,200,000 red blood cells and 15,000 whites, as compared with 3,800,000 red cells and 18,000 whites on June 23. A proctoscopic examination showed the mucosa to be somewhat pale and anemic but absolutely free from any kind of ulceration or other abnormality. No mucus was present, except in normal state, and no amebas were to be found in the excreta. July 16, was the last visit of the patient and on this occasion the mucosa of the lower bowel showed a decided improvement over the condition existing five days previously. The anemia of the mucous membrane was no longer present, and as before, no ulceration was evident. The patient said he felt like a different man, was having but one movement a day, rarely two; stools were perfectly normal in character and to all intents and purposes a cure had been effected.

This case must impress the reader with the remarkable powers of emetine when injected hypodermically. Suffering from a constant diarrhea for nearly fourteen years, a mere shadow of his former self in body and mind, subjected to the ravages of *Amœba histolytica*, abetted by germs in the lower bowel, finding a perfect media in the ulcerated areas; this man was relieved after three daily injections for the better part of three weeks, and at the end of three weeks was cured. Quite true is it that equally remarkable results have been observed following appendicostomy; but it must be borne in mind that whereas one is a major operation, attended with those dangers with which general anesthesia and intraperitoneal manipulations are always fraught, the other is a simple procedure —merely the administering of a hypodermic injection, a procedure which, if necessary, could be performed by the patient himself at any place or at any time.

Case III.—J. S. No. 281. Age 26. German Sailor. Present condition dates back to a sojourn in India, one year ago, since which time patient has had a steady diarrhea. This consists of a bloody mucus, watery stool, more frequent at night, at which the patient claims he has movements as frequently as one every hour. Proctoscopic examination showed that *Amœba histolytica* was present, together with the typical ulcers of amebic dysentery. The general condition of the patient was good and on July 27 the injection of one-half grain doses of emetine was started and continued for seven days. The arms of the patient were utilized as the site for injection. After two injections the bowel movements dropped to one a day and so continued to the end of treatment, at which time the proctoscope showed that the lower bowel was clear of ulceration. Further trace of the patient was lost, as he failed to return after the seventh day. It is presumable that he had no further difficulty.

There is a fourth case, a private patient of Dr. Lynch's, that also responded most ideally to injections of emetine; but, unfortunately, the history and data of this case have been lost, and we are unable to cite the case in detail.

First thought might lead one to assume that four cases are only too few from which to draw conclusions or upon which to base statements of substantiation. The work and reports of other observers, however, are all characterized by the similarity of results, results which can be summed up in one word, "cure." Marvellous as the results obtained by the hypodermic injection of emetine, more wonderful still is the rapidity of action. As our cases show, within a few days of the initial injection, improvement is most marked. The number of movements decreases within three days, blood and mucus disappear from the stools in a period equally brief, while at the end of a series of seven injections of one-half grain of emetine each, the patient is apparently cured, the ulcerations within the bowels healing in that length of time. In none of our cases has the *Amœba histolytica* been identified in the stools or mucus after the first injection. The most skeptical cannot fail to be impressed by the apparently deadly effect of emetine upon the ameba of dysentery.

Ipecac has been used for years in the treatment of amebic dysentery, with variable success. There have been many other medicinal remedies recommended, and only recently, as stated above, has salvarsan been used as a curative measure. There is no question, however, that medicinal treatment, up to the time of the use of emetine, has not been

attended with constant success, and operative treatment has been resorted to. The object, of course, being a ready means of irrigation of the lower bowel. Two operations have been utilized, the cecostomy, as devised by Gibson; and appendicostomy, first used by Weir. The latter, to date, has been used more frequently and seems to be the operation of choice. Dr. Lynch, who has performed appendicostomies on over one hundred cases of amebic dysentery, has never met with any untoward results, and has never failed to effect a cure, providing the bowel was irrigated for a sufficient length of time. In these cases the opening was left for a varying length of time, depending upon the condition of the lower bowel, and the irrigations were always continued for some time after the bowel was free from ulcerations. The kind of solution used in irrigating the canal was of no material consequence, as the purpose is to keep the bowel clean. In the average case the appendicostomy opening was not closed before a lapse of two years. In the past year Dr. Lynch has been performing the operation under local anesthesia, thereby greatly lowering the operative risk. No difficulty has been experienced in performing the operation in this manner, and we thought the ideal method for treatment was at hand. Then came reports of the wonderful success of Rogers in his treatment with emetine, and in the light of present results it would appear that the day of appendicostomy in amebic dysentery has passed.

The purpose of this paper is not to describe amebic dysentery, but the author of this paper would like to impress upon his readers that amebic dysentery is not endemic or epidemic alone in the tropics. There are many cases in this section of the world, and only too many of them are not diagnosed. The reason for this, perhaps, is due in part to inadequate facilities to assist in arriving at a diagnosis. It is not easy for the inexperienced to demonstrate the amebas in the stools, particularly when it is remembered that below 65° F. the ameba ceases to move. On the other hand the man who has seen a number of cases recognizes the typical ulcers in the bowel, on proctoscopic examination; but, here again only too few of us resort to proctoscopic examinations when a patient comes with diarrhea. Now, however, no case of persistent diarrhea should escape our hands without first proving to our own satisfaction the presence or absence of amebic dysentery. As Rogers has shown, emetine is a diagnostic specific. A few doses of emetine, injected hypodermically, will result in improvement in a diarrhea providing it is of amebic origin; on the other hand, if due to some other cause, the emetine is without effect. There is no danger attendant on its use, no constitutional effects ever having been observed. Indeed is this to be marveled at when one considers the deadly action of the drug upon the ameba.

We have had no experience with the drug in the treatment of liver abscess due to amebic dysentery, but as Rogers has shown, the drug is as potent as in an uncomplicated case of dysentery. For some unknown reason the occurrence of liver abscess, complicating amebic dysentery, is not as frequent with us as in the tropics, though no doubt many of the liver abscesses brought to the operating table could be traced to an amebic origin.

From our own experience with emetine hydrochloride injected in cases of amebic dysentery we draw the following conclusions:

1. Emetine hydrochloride is a specific in dysentery due to *Amœba histolytica*.
2. The method of administration is hypodermatically in daily doses of one-half grain of emetine hydrochloride dissolved in sterile water, extending over a period of seven days.
3. The effect upon the pathological condition is most pronounced and immediate. At the end of seven days all the symptoms of the disease have disappeared.
4. The patient shows no ill effects from the use of the drug.
5. To date there has been no reason to suspect the possibility of recurrence.
6. Two or more doses may be injected in cases of diarrhea to assist in diagnosing the origin of the dysentery. Improvement indicates an amebic dysentery.

January 5, 1914. Since the writing of this article two additional cases have been treated with emetine hydrochloride with results similar to those obtained in our other case.

Within the past week, two of the cases originally treated have returned with recurrences. In each the amebas were found though the diarrhea had been of but a few days duration. Emetine treatment has been promptly instituted.

Recently there have been other reports of recurrences, so it would seem that intermittent treatment with emetine is necessary.

# SOME REMARKS ON THE MEANING OF DREAMS.*

By MEYER SOLOMON, M.D.,

CHICAGO.

ASSISTANT ATTENDING NEUROLOGIST, MAIMONIDES HOSPITAL; INSTRUCTOR IN PSYCHIATRY AND CLINICAL PSYCHIATRY AND INSTRUCTOR IN NEUROLOGY, COLLEGE OF MEDICINE, UNIVERSITY OF ILLINOIS, CHICAGO.

THE subject of dreams has taken on a new interest to most of us since the origin of the psychoanalytic movement. Whereas, previously, most dreams were looked upon as curious products of the imagination, without meaning or significance, and of no practical value whatever, we have now come to appreciate that dreams are not merely the insignificant and meaningless conglomerations of a wandering mind. We now know that there is a meaning to every dream and to every portion of a dream; that there is a reason, a definite explanation for the trend and content of the dream thoughts; that it is frequently important to be able to analyze and interpret dreams; and that there is a real, practical benefit to be obtained by a study and understanding of the mental processes and mental content of dreams.

The members of the Freudian school have given considerable attention to the subject of dreams. Freud has devoted a book to the "Interpretation of Dreams." About dreams as a basis an extensive psychology has been elaborated by the Freudian school. This psychology is the basis of the Freudian method of psychoanalysis and is the

*Read at a meeting of the West Side Physicians' Club, November 21, 1913.

groundwork upon which as a foundation most of the sweeping and dogmatic conclusions of the Freudian school have been built up.

It is not my object here to attempt to explain the principles of the Freudian psychology. Nor shall I enter into a comprehensive exposition of the Freudian conception of dream interpretation. This has already been done by many writers, and articles along this line have previously appeared in this journal and elsewhere. I shall, however, be compelled to enumerate the essential points in the Freudian conception of the meaning and interpretation of dreams. This I must of necessity do, since I wish here to present certain views more or less diametrically opposed, in many respects, to the Freudian viewpoint; differing from it in others and agreeing with it in still others.

Let us, therefore, note, categorically, the main conclusions arrived at by Freud and his school with respect to dream analysis and interpretation. For a full exposition of the Freudian conception the reader is referred to Freud's "Interpretation of Dreams" and to the writings of certain Freudians, particularly Jones and Brill here in America. In this paper, as above stated, I shall merely note the essential landmarks of Freud's contention.

Very briefly stated, Freud's ideas concerning dreams and their meaning may be summed up as follows:

(1) The law of rigorous psychical determinism holds true for dream life. This means that for every psychic state, for every idea in the dream there is a logical and efficient antecedent causative mental state in the present life of the individual. All the dream thoughts are related to one another and are of more or less intimate significance to the dreamer.

(2) Dreams express wish-fulfilment.

(3) The underlying thoughts or sources of the dream are always unconscious; they are (4) generally of infantile origin, and fundamentally are (5) usually of a sexual nature.

(6) The dream is the result of a struggle between repressed, unconscious tendencies striving for recognition and what has been called the endopsychic censor, as a result of which a compromise is brought about so that the hidden thoughts, unacceptable to the individual in their naked form, and constituting the latent content of the dream, are transformed into other, more acceptable forms, which go to compose the manifest content of the dream (which is the dream as we have it), this manifest content thus symbolically expressing the meaning of the latent content. Various mental mechanisms are employed in a free and high-handed manner to bring about this transformation which is purposive and which accounts for the strangeness, the bizarreness, the shifting scenes, the changing persons, the kaleidoscopic, crazy-quilt, topsy-turvy tendencies of so many dreams.

(7) Thus the function of the dream is to guard sleep, to prevent certain disagreeable thoughts from appearing in undisguised form. When the dream is not accomplishing its purpose of properly transforming the latent content by the free employment of symbolism, no matter how far-fetched, the endopsychic censor rouses the dreamer who, by awaking, prevents these unacceptable thoughts or ideas from disporting themselves in nude form in the dream.

The forgetting of a dream is also purposive, the most significant parts being frequently earliest and most completely forgotten, the least important being longest and best recalled. The distortion of dreams during the waking state is a continuation, in greater degree, of the distortion taking place during sleep.

In fine, according to the Freudian conception, dreams are the result of an intrapsychic struggle. They usually represent, in disguised form, the repressed sexual strivings of the individual. Somatic and external stimuli and recent experiences, generally of the day before, although woven into the dream, are merely inciters of the true dream thoughts, which, in their ultimate analysis, are found to be of a wish-fulfilling nature, unconscious, of infantile origin, of sexual nature, hitherto repressed, hidden, kept in subjugation, but continually lurking in the dark and ever silently but powerfully striving for expression and unconsciously guiding the individual during his sleeping and his waking state.

To analyze a dream thoroughly, therefore, and unravel its true, underlying meaning, the psychoanalyst must, according to the Freudians, penetrate to the infantile and early childhood life history. Dreams will then be seen to be a means of gaining various sense-gratifications and emotional heavings which Dr. Putnam of Boston would classify as sensuous or sexual. With this classification I cannot agree since it would mean that all feeling, all affectivity, all bodily yearning, hence all human energy, in fact the vital energy of the universe, would have to be called sensual or sexual and be included within the meaning of the term libido. On the other hand, most Freudians, in employing the term sexual, include under this heading, in addition to the usual meaning, all possible incestuous, bisexual, narcissistic, and polymorphous perverse sexual tendencies, physical and psychical, conscious or unconscious. It is in this latter sense that infantile sexuality is commonly and almost universally used by Freudians, and it is from this standpoint that they conduct their analyses and interpretations.

I shall not here take up seriatim these beliefs of the Freudian school and analyze them with regard to their truth or fiction. A few of these points are discussed to some extent in previous papers. I shall, however, without comparative discussion pro and con, enumerate the points on which I take issue with Freud's conception of dream interpretation. To discuss the various points of difference of opinion would require more time and space than can here be devoted to the subject at hand.

The author's conception of dreams, very briefly sketched, may be stated as follows:

(1) The law of psychical determination does hold true for dream life. True, for every psychic state, for every thought in the dream, there is and must be a logical and efficient antecedent causative mental state. But this mental state cannot always have occurred in the present life-history. On the other hand, the entire ontogenetic and phylogenetic history, the evolutionary life-history, must be taken into consideration. When this is done we find that our instinctive tendencies, physical and mental, play a prominent part. Moreover, although all thoughts, tendencies, activities, and reactions have a valid cause, which occurred in the past, nevertheless all these states, even when closely related and of a similar nature, do not necessarily show a cause-to-effect relationship between early and late experiences, nor is any special intimacy to the individual

indicated by the appearance, due to association, of any of these.

(2) Instead of wish fulfilment, which is not a broad enough term and does not include all fears, I would say that the biologic tendency, conscious or unconscious, toward *self-expression* is the real driving force of the dream, and, incidentally, of all other mental states (which merge by an imperceptible series of gradations one into the other and which differ from dreams primarily and essentially in degree of consciousness).

(3) The basic sources of origin of dreams are not necessarily of an unconscious nature, using the term unconscious in the sense in which it is employed by the Freudian school. If subconscious were used in a broad sense, as including co-conscious thoughts (those just beneath the realm of clear consciousness, Prince)—corresponding to Freud's foreconscious and unconscious (the latter being really physiological in nature) mental processes—then I should be willing to admit the term unconscious. But if all past experiences, all memory, physiologically and biologically, temporarily or permanently forgotten, be referred to as unconscious thinking, then I cannot agree to the use of this term. Dreams are at bottom composed not only of so-called unconscious thoughts and tendencies but of thoughts, tendencies, activities, and yearnings of all degrees of awareness and significance to the individual, and of a varying life-history both as to age and intensity.

(4) Dreams are not primarily of infantile origin. Infantile and early childhood experiences, tendencies and activities play a very important part in determining our later lives, and hence our dreams, but, besides these early influences and determinations, recent experiences, presleeping thoughts, especially of the day before, and various somatic and external stimuli play a most important rôle in dream content and dream formation. As a matter of fact, any portion of our past life, up to the very moment of the dream thoughts, plays its part. And, in the end, it is the instincts which are really at the bottom of all dream activities—as of all other tendencies and activities, physical or psychical, conscious or unconscious.

(5) Consequently, any one or more of our instincts may be the root of the dream. It is about the instincts as nuclei that our mental life is built up. Hence, in the ultimate analysis of a dream or of any other mental state, as a final explanation of a certain tendency, activity or reaction, we come upon our instincts. The material with which our instincts play may be taken from any portion of our lives.

(6) Let us next endeavor to learn the significance of the mental processes during sleep. Briefly stated, we can explain them in the following fashion: Sleep is an instinct. It is just as much of an instinct as are eating and other similar processes. Sleep is a biological and physiological defense against the possibility of fatigue and exhaustion. The sleeping state is characterized by a certain degree of consciousness which is much lower in the scale of mental evolution than that which is present in the waking state. Reasoning, judgment, critique, intellect, logical and orderly thinking are greatly lessened; creative activity is slight or absent. There is a return to free play on our instincts and emotional strivings, the material being furnished by the past (recent or remote) mental content or make-up of the dreamer. Some dreams may deal with particular, intimate experiences, centred about one or the other of our instincts. Other dreams may have to do with experiences or thoughts which are not specially important to the dreamer or make only a feeble appeal to one or more of our instincts. In the latter case association, and flight of ideas, often initiated by peripheral stimuli, is apt to be very marked, touching upon this or that past experience or tendency or thought; related first to this, then to that instinct. The experience may be of any degree of intimacy. Association of ideas is frequently determined by the law of chance or probability, as conditioned by the expectations or anticipations of the dreamer, this being dependent, of course, upon his past life history. Retardation of one portion, scene, idea, etc., and anticipation of another may result in fusions, condensations, reversals. These may or may not be of significance. This will explain the protean manifestations and the helter-skelter, panoramic, kaleidoscopic, apparently purposeless tendency of so many dreams.

Repressed ideas may make their appearance in dreams. But they are brought into play in exactly the same way that insignificant ideas are woven into the dream. There is no special transformation of "latent" into "manifest" content, no special symbolism is employed, no ever-present intrapsychic struggle is going on behind the scenes. It is just like in the waking state—but on a lower order. The same symbolism, the same intrapsychical struggle, the same mental mechanisms are found in dreams as in the waking state, except that in the former thinking is less logical, less orderly, more loose, less critical, is guided much more by our instinctive reactions and tendencies, and our emotional strivings.

(7) As to the function of the dream it may be said that so long as any appreciable degree of consciousness exists, there must be some degree of mental activity. This mental activity results in the dream, during which thoughts of recent or ancient origin play havoc with our instincts and emotions.

The forgetting of a dream is essentially, biologically and physiologically and not individually purposive, although, by the exercise of repression for one reason or another, the individual factor may be brought prominently into play. It permits the clearer consciousness to once more deal with the cold, hard facts of the real, waking life.

In short, according to the writer's conception, sleep is physiologically and biologically useful and necessary, and easily explained. So, likewise, with the mental processes during sleep. The mental material may be of any date of origin, and of any degree of intimacy; the mental processes may be of any degree of clearness, directness and logicalness; not the infantile experiences alone, but rather the instincts are at the bottom of dreams; not only the sexual instinct but any one or more of the instincts may be the groundwork of the dream; not mere wish-fulfilment, but rather self-expression or self-preservation (in the broad sense of preservation of the bodily and mental personality or individuality) is at the bottom of all dream life; furthermore, ideas of all degrees of consciousness or awareness may be employed. Dream thoughts and mental processes run the gamut of possible variations of like conditions occurring in every-day life. They vary from simple to very complex; from clear and definite to vague and indefinite presentations; from a brief, direct, clearly remembered dream to a long,

circuitous, hazily recalled dream; from a very significant to a most insignificant dream; from dealing with recent experiences to the employment of early childhood and even infantile mental material; from appealing to one instinct to touching the chords of several instincts; from showing us the recent heart-pangs, wishes, fears, disappointments, cravings, etc., to showing us the instinctive make-up and underlying personality of the dreamer. And so we can enumerate all the varieties or types of dreams. They are as numerous and as different as are the individuals about us; as numerous and changeable as are our feelings, emotions, sentiments, passions and moods.

Sometimes they lay bare the soul of the dreamer. At other times they show those hidden, instinctive forces which are ever urging us on and on and, like an octopus, stretching forth their tentacles in all directions, forming the foundation for the springs of conduct which make us what we are and which are characteristic of our personalities.

He who understands dreams understands human psychology. He who can analyze a dream and properly interpret it is at the very root of psychoanalysis.

The analysis of dreams may be important in the diagnosis and treatment of certain mental disturbances, particularly the psychoneuroses. But the most practical use of dream analysis should be its value in permitting us to understand the workings of the normal and abnormal mind—in understanding Man.

The Freudians have justly made dreams the central theme of their psychoanalytic work. It is upon dreams as a basis that psychoanalysis is developed. If our ideas with regard to dreams be incorrect, then the foundation for our psychoanalysis is faulty, our conclusions are false, and our work has not only been of no avail but actually harmful, and actually pernicious. If the author's conception of dream analysis and interpretation be well-founded, as he believes it is, then, it seems to him, it is of the utmost importance to correct our notions with regard to certain conclusions of the Freudian school of psychoanalysis.

This paper deals with the subject very briefly. Detailed explanation and discussion have not been entered into. Nor are any illustrative dream analyses here presented because the writer desires to present, in the briefest possible manner, only the essentials of dream analysis and interpretation. For a somewhat fuller discussion of the writer's views, and for the presentation of dream analyses from the standpoint here discussed, the reader is referred to other papers by the writer.*

**Concentrated Solutions of Neosalvarsan.**—P. Ravaut has employed glass ampoules containing the ordinary doses of neosalvarsan dissolved in 8 c.c. of distilled water. He finds that these concentrated solutions eliminate the toxic febrile effects attributed to the large volumes of water usually used. He has kept these ampoules for two months, and has found that the contained solution is in no respects inferior to that prepared with freshly distilled water.—*La Presse Médicale.*

## THE HEALY PUZZLE PICTURE AND DEFECTIVE ALIENS.

By M. K. GWYN, M.D.,

NEW YORK.

SURGEON, U. S. PUBLIC HEALTH SERVICE.

THE problem of the feebleminded is one of growing importance and is attracting a great deal of attention. Whether the condition is one of pure heredity; due to the lack of some internal secretion; or due to some poison within the body is still to be determined. Each school has its numerous followers. The Eugenists point out the presence of a strain of feeblemindedness in families, and have collected a large amount of data in support of their contention. There are records of two especially famous ones, the Jukes and Kallicak families which are quoted rather extensively. The transmission of anatomical characteristics is capable of demonstration by direct animal experiment, but in the human being it is necessary to depend upon such cases as may be run across from time to time. Every one is familiar with the resemblance of the members of an immediate family, and deformities like supernumerary fingers may be traced through two generations; but to say that a condition of defective mentality may be traced through several generations extending over a period of a hundred years or more is open to question.

Cretins are an example of lack of internal secretion. Fed upon thyroid gland, they improve both mentally and physically. Work has been done along this line by feeding pituitary gland to feebleminded persons, but the results so far are not very encouraging.

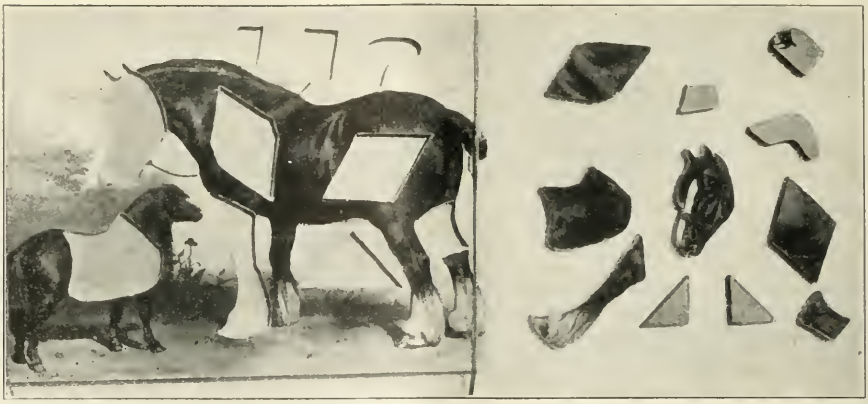
That feeblemindedness is due to a poison of some kind, is on a theoretical basis. It has much to recommend it. Whatever may be the cause of the condition, there is no question that something must be done to control it if possible. Of course, if the absolute cause were known, then a definite attempt might be made to eradicate the condition, but as it is, the best that can be done at present is to ameliorate it as far as possible.

First, institutional treatment appears to be the best method of attack offered at present.

Second, educational treatment in the public schools, by segregating these unfortunates in special classes under skilful teachers. The special classes in the public schools undoubtedly do some good, but it is doubtful if the returns justify the amount of time, money, and energy expended. The child after school hours is back on the streets, a danger to every normal child with which it comes in contact. In the institution they are continually under observation, and what is more important, they are separated from normal children.

Another phase of the feebleminded problem is one that is especially important to the Public Health Service, and that is to prevent as far as it is humanly possible the introduction into the country through the immigration stream of these undesirables. It is a unique problem in that it is not alone one of diagnosing the condition, but of picking out from the enormous number of aliens entering the country those who are defective. How far they are successful is shown by the increasing number of feebleminded deported during the past two years over that of previous years.

Given a history by parents or school teachers extending over a period in which the child has been under observation, the fact that a defect exists is



Picture-puzzle Test Made for Alien Defectives.

usually not difficult to establish. All these agencies have in view the helping of the child, and the examination is made to determine the best method of treatment to adopt.

With the Public Health Service Officer the problem is essentially one of diagnosis, without aid from parents or other agencies who might help. It is complicated by the large number of races involved; each one of which presents its particular characteristics, which only a large experience permits them to make allowance for. A large number are illiterate and come from a very poor environment. Once the diagnosis is determined the case is reported to the Board of Special Inquiry of the Immigration Service for action. Under the law these cases are mandatorially deportable, so that for the alien it is a serious thing.

A great deal of work has been done during the past two years in detecting the feebleminded among aliens arriving at Ellis Island. The Simon-Binet tests were tried out but found to be impractical on a large scale. They required too much time in the first place, and in practice were not found suited to illiterates. It was necessary to secure tests which could be used in common among a mass of people of various races, or varying school advantages, together with a large number who were utterly illiterate.

The most hopeful method appeared to be a series of performance tests. What may be called the Healy frame, and the Fernald test, and the Healy Picture Puzzle, taken from the series of tests devised by Healy and Fernald have been found of great value. To show the value of the picture puzzle in determining feeblemindedness among defective immigrants, a small series has been tabulated from the case histories available at the present time. The time only has been recorded, and ten minutes allowed for the test. The picture with the cut out parts lying by its side are shown to the alien, and he is told that this is a picture which can be completed by filling in the vacant spaces with the pieces lying by the side of the picture. He is also told that the pieces will all go in easily when placed in the right position, that it is not necessary to use force. The parts are so cut as to give a clue to the correct position by shape and color and reference to animals in the picture. If successful the time is recorded in minutes and seconds. A failure is recorded as "F" followed by the time within ten minutes during which the alien works at the test before deciding that he can not do it. Normal aliens over 16 years of age will usually solve the picture within two minutes; defectives, on the other hand, require more than five minutes, if they are successful at all. The main portion of the picture gives comparatively little trouble except to the idiot and imbecile, who here fail utterly. The fitting of the two component triangles into the large triangle takes ordinarily twice as much time as the rest of the picture. It is here that the defective shows up so glaringly with his absurd mistakes. The fact that the two right triangles are the component parts of the isocles triangle is not noticed at all until by a process of elimination by fitting the rest, they are the only two pieces left on the board. At this point I have frequently seen the alien lift up the board and look underneath to see if there were some parts missing. Almost invariably this is left to the last, although during the fitting of the rest of the picture he may pick up one of the triangles only to drop it immediately in favor of some other part of the picture. Although no single test is sufficient for a diagnosis as a general thing it will be found that immigrants who take more than three minutes to correctly solve this puzzle should be gone into further before deciding that they are normal. It has been found in practice that an alien who solves the picture puzzle in two minutes or less will usually solve the Healy frame and Fernald test equally as well, but I have not been able so far to determine the lower age limit at which success is attainable for the picture puzzle, as most of my cases have been over sixteen years of age. But the few instances in which I had an opportunity of testing the picture puzzle in nine, ten, and twelve-year-olds they have failed to solve the triangle although successful with the rest of the picture.

At present this puzzle appears to be essentially an adult test, that is to say that although those under sixteen are successful in filling in the geometrical portions of the puzzle and the portions of the figures cut away, with the exception of the isosceles triangle, it requires the adult type of mind to solve this latter difficulty.

From the results tabulated in the accompanying table, of twenty-two feeble-minded aliens it will be seen that ten failed utterly, twelve were successful after working from 2 minutes and 22 seconds to 7 minutes, eight requiring more than 4 minutes.

There was one case aged thirteen years and one aged eleven years in the series; the rest ranged from sixteen to forty-four years.

The sexes were evenly divided.

Only three members of the group could read and write.

## A VEGETABLE HORMONE IN CASES OF ILEUS AND GASTRIC DILATATION.

By DOUGLAS H. STEWART, M.D.,

NEW YORK.

EMETOCATHARSIS may be produced by swallowing putrid cheese, decomposed shad-roe, or an overdose of podophylin. Control dictates the use of the plant-product if remedial measures are the desired aim. Even the lowered blood pressure, collapse, and other possible bad effects of hormonal might be avoided by substituting the aforesaid podophylin were it not for the five to ten days of severe pain which its injection causes. Yet the best synergists to cascara are this very podophylin (and belladonna) for internal administration and physostigmine and arecoline if hypodermic service is prudent. Cascara, frangula, and senna will serve as examples of exciters of vermicular constriction in the intestine, blood absorption being the preliminary to the action of such vegetable hormones. This paper will limit itself to cascara.

Veterinarians have experience with hypodermic purgation. The horse eats hay, but possesses a small stomach and a one hundred foot intestine. These anatomical and dietary conditions have led to the discovery that when physostigmine fails arecoline will suffice and *vice versa*. I have always begun with the first and followed with the second, but the reverse is usual in veterinary practice.

E. C. Dudley has used a preparation of cascara bark in 32 cases. With one patient it was successful alone, with ten it required annexed measures (physostig, enemata, etc.), and in the remainder all treatment was absolutely ineffective. I, too, have sometimes passed through that "absolutely inefficient" stage aided by the very best consultants that I knew. If the preparation be the same I think it should be given during or prior to anesthesia. This holds true of pituitary extracts, etc., because if distention once takes place its persistence so thins, stretches, and exhausts the musculature that peristalsis is put beyond attainment. There should be an earnest attempt to forestall the possibilities of meteorism by initiating preventive measures in advance of their need. Waiting for clear indications may mean that one's best but belated endeavors will obtain the doctor's well delineated word picture and secure "absolute inefficiency" as a terminal result.

Call the vicious circle either preanesthetic purgation or post-cathartic anesthesia it means a hurt, over-stimulated, or dehydrated bowel at a time when prophylaxis demands an empty colon and noninterference with the small intestine, which latter is the "lion in the way" or the "sleeping dog" so far as the operator's chances of success are concerned. It is a funnel the caliber of which is arranged to promote an upward movement of its contents; it is a barrel hooped inside and unfit to withstand internal pressure; its motive power depends upon the impetus of peristalsis from above downward and yet when pinched between one's fingers and thumb it immediately starts a contraction on the "distal" side.

After testing the quality of the ingredients have capsules made containing cascara gr ii, podoph., gr 1/8, ext. belladon., gr. 1/16. Three hours before anesthesia give an enema and two such capsules. Repeat these in one hour and then the peristaltic wave would be started in the precise direction; but it may be postponed, at the will of the surgeon, by the use of morphine and without possibility of salivation, occult blood, or other evil consequence of drug retention. Proceed with two capsules night and morning till the bowel movements are redundant, then diminish the dosage according to indications but persist in the daily administration of a suitable quantity, for thirty days or longer, to forestall late symptoms which sometimes appear after the patient has returned to a more or less distant home. Should excessive vomiting persist on the second day replace the capsules with a hypodermic of cascara (active principles) combined with (gr. 1/50) physostig. salicylat. Repeat the latter in one hour. If no flatus is passed give it a third time at the end of the second hour. Ten minutes later administer an alum enema. Should inefficiency persist for a half hour longer give (gr. 1/10) arecoline hydrobromide. Repeat this in another hour, if absolutely necessary. Should everything fail and marked distention appear, then stop the action of the splanchnic nerves (rami communicantes) by lumbar anesthesia.

Inhibition is more persistent than contraction, since the constrictor fibers lose their irritability sooner, but even powerful peristalsis may be brought to a standstill by electric stimulation of the splanchnics. On the other hand a man's bowels may be moved by over-stimulation of the motor fibers of the pneumogastric-spinal accessory (*e.g.* in death by hanging). Just why this happens belongs to the province of physiology, and its discussion may be omitted here. Lavage and all other valuable aids must be taken for granted, if indicated, as they surely will be as a sequence of procrastination in initiating the downward tendency of the peristaltic wave which the relaxation of deep anesthesia has a tendency to reverse.

The usual cause of failure to empty the bowels with lumbar anesthesia is an hypertrophied sphincter ani, commonly caused by uterine, septic, or prostatic troubles. Dilatation is necessary and fortunately easy.

*Summary.*

1. In laparotomy danger should be considered the normal.

2. Cascara is a peristaltic excitant.

3. Get the wave under way in the right direction.

4. Start preventive measures in advance of anesthesia.

5. Use internal administration of remedies, if possible.

6. If impossible, employ the hypodermic syringe.

7. By hypodermic, give combined active principles of cascara reinforced by eserin.

8. Aid them with arecoline.

9. Maintain the downward wave for at least 30 days.

10. There are distentions in which all measures must fail, but the plan proposed will lessen their number.

11. As a last resort lumbar anesthesia, plus dilatation of sphincter ani, is invaluable.

128 West Eighty-sixth Street.

## THE TREATMENT OF DEAFNESS WITH SONOROUS VIBRATIONS BY THE ZUND-BURGUET METHOD.

By LESTER MEAD HUBBY, M.D.,

NEW YORK.

All the cells of the body must functionate or degenerate. In subnormal hearing all the physiological processes of the entire auditory apparatus (the membrana tympani, tympanic ossicles, and muscles, Corti's organ, auditory nerve fibrils and nuclei, and all the auditory central nuclei in the medulla, corpora quadrigemina, cerebrum, etc.) functionate only a fraction of the amount that occurs in health. For instance, if the hearing is reduced to one-thirtieth of the normal, the auditory nervous system receives one-thirtieth of the impulses received in health. This continuous reduction (for the auditory apparatus never absolutely sleeps) has its necessary sequelæ not only on the parts actually used but also on the neighboring structures such as the tympanic and Eustachian mucosa, the labyrinth, etc.

The application of sonorous vibrations of sufficient intensity at the external auditory meatus, affects the different parts of the auditory apparatus in the following ways: Vibratory massage is produced on the external auditory meatus and all its parts, such as the ceruminous glands, etc., increasing their circulations and functions. The membrana tympani is massaged and also vibrated within physiological limits. The ossicles and the hair cells of the organ of Corti are exercised. The tympanic mucosa is stimulated by the vibratory massage transmitted through the membrana tympani and by the exercise of the ossicular chain. The Eustachian mucosa is stimulated by the vibratory massage of the tympanic portion and its venous circulation is also bettered by the improvement of the tympanic venous circulation. The tensor tympani and stapedius muscles are exercised and therefore their circulation and metabolism are increased. The internal ear is massaged by the vibratory waves in the endolymph and perilymph. The auditory nerve fibrils and nuclear cells (peripheral, along the course, and central) are exercised—their efficiency therefore developed.

Thus it is evident that all the constituents of the auditory apparatus are stimulated and their circulation and metabolism improved.

Stimulation of the auditory apparatus of the deaf by sonorous vibration is not a new idea. From the first century A. C. when Orchigène, a Greek physisian from Alexandria, used sounds of varying intensities for improving the hearing of deaf-mutes, up to the present time, various sounds and exercises have been tried with more or less success.

Thus the human voice, bells, clocks, tambourines, the flute, whistles, tuning forks, the accordion, the phonograph, sirens, etc., etc., have been utilized as means of stimulation.

Since the hearing for the human voice is the especial objective of all treatment for deafness, the use of instruments not containing the tones and harmonics of the human voice can not be of much value in developing the perceptions for the latter.

For instance, with the pure tones of the tuning-forks, perceptions for the latter especially are developed and all the intermediate tones and harmonics are neglected.

The use of the human voice of one individual as an excitant can be utilized only for a short time each day, as the required intensity is too great for even the strongest voice to bear without injury. Moreover at least three voices should be used each time, namely of low, medium, and high registers.

Urbantschitsch has successfully used the voice supplemented by his accordion, but the length of his course of treatment is prohibitory.

The phonograph has too many extraneous noises (the noises of the needle producing the original record, the noises of the needle used in the reproduction, the exaggeration of other noises, etc.). The prominence of the extraneous noises prevents the proper increasing of the intensities of the tones desired, and the impossibility of sufficiently varying the sounds, produces a monotony which is exceedingly trying in a long series of treatments.

The sirens of Marage are open to the same objections as the tuning forks. The hearing is improved for certain vowel sounds only and the course of treatment is exceedingly long and tiresome,—half-hour treatments for a period of many months.

The Meyer-Rowan instrument is constructed as follows: It has faradic hammers which strike on mica plates over four cylindrical chambers of different dimensions. These hammers cause the air in the chambers to vibrate, thus producing three different notes depending on the different sizes of the chambers. By opening or closing the connections with the other chambers the tones are varied in pitch. In this way several notes can be produced with each of the four chambers. Rubber tubes carry the sounds directly to the ears.

Suction or compression can be exerted on the ears by means of a piston pump attached to the system of tubes. A pneumomassage motor is also connected.

The objections to the instrument are as follows: The notes produced are too few, they contain too few harmonics, and their intensities cannot be sufficiently controlled. The use of either the piston suction and compression pump, or of the pneumomassage motor, is liable to cause harmful stretching of the membrana tympani.

The electrophone of Zünd-Burguet comes nearest of all instruments thus far devised in fulfilling the requirements in the treatment of the deaf by means of sonorous vibrations.

It covers the range of the human voice. It contains about the same harmonics. By means of the three registers, the timbres of three voices (low, medium, and high) are produced. The amplitude

of the vibrations can be instantly varied to stimulate each ear according to its separate requirements. The intensity of the sounds can be raised sufficiently so that the length of treatment is not fatiguing to the patient or the operator. The tones can be maintained at a given intensity as long as is necessary. The length of the course of treatment is not nearly so great as that of the methods of Urbantschitsch, Marage, Dussaud, etc.

In its essential details the instrument consists of three faradic hammers, whose lengths can be altered by means of levers; telephonic ear receivers; switches for altering the intensities of the sounds to each receiver; switches for shifting the current to the different registers; a switch for shifting the current to both receivers at once or to a single receiver; an ampèremeter to show the amount of current passing, and a volt-meter to show the condition of the battery used.

The usual method followed is to give a course of 50 treatments of three minutes duration, two treatments a day. This can be varied somewhat to suit the requirements of the patient. One treatment a day can be given to those who find it impossible to come twice a day. This is not so effectual and is not to be recommended.

A very good method is as follows: 30 treatments, two given each day. 4 to 6 weeks of rest. 20 treatments, two given each day. 1 to 3 months of rest depending on the progress of the case. Then 10 to 12 treatments every 3 months, two treatments each day.

For obstinate cases the following method may be followed: 50 treatments, two treatments a day. 1, 2 or 3 months of rest, not more. 30 treatments, two treatments a day. 1, 2 or 3 months of rest. 20 treatments, two treatments a day. Then 10 treatments every 3 months, or 20 to 30 treatments every six months, two treatments being given each day.

But no rigid system can be outlined in advance. Each individual must be studied and the appropriate method selected.

Functional examinations are made before beginning the course and after the fifteenth, thirtieth, and fiftieth treatments.

By these examinations an accurate measure of the progress and an estimate of the probable length of treatment can be obtained.

The treatment consists in continuously playing scales on each of the three registers separately, shifting from one ear to the other, the rapid varying of the intensities of the sounds by the finer adjusting button during the production of the scales, the varying of the intensities by coarse shocks produced by shifting the primary button while making the scales, the production of jerky scales, etc., etc.

All these exercises can be changed in many ways at will. The intensities of the tones to each ear must be altered frequently to meet the changing sensibilities of the two ears.

After each treatment there are often some subjective sensations in the ear such as a feeling of fulness, numbness, etc. Zünd-Burguet overcomes this with a Delstanche vibrator, gently used. I prefer to use a mechanical vibrator on the skin in the neighborhood of the ear and also over the pinna, care being taken not to cover completely the external meatus.

Indications.—Some improvement is to be expected in all diseases of the sound-conducting apparatus such as otitis media catarrhalis chronica, otitis media chronica residualis, radical mastoid deafness, partial ankylosis of the ossicular chain, and also secondary partial so-called nerve deafness, and otosclerosis if not too advanced.

In subacute otitis and chronic purulent inflammations of the middle ear, the treatment can be gradually and cautiously tried. The improvement of the circulatory tone due to the stimulation of the tympanum by the vibratory massage is said to be very efficacious in these conditions.

Psychic functional deafness is said to be often curable by this treatment, through its strongly suggestive therapeusis, and its stimulating effect on the auditory perceptive apparatus.

The following claims have been made for the treatment: The ceruminous secretion becomes more normal. The Eustachian tube becomes more healthy, and if it has a tendency to remain too closed, its patency increases, provided there is no organic stricture. The metabolism and health of the tympanic and Eustachian mucosa improve. Partial ankylosis of the ossicular chain decreases and sometimes disappears. The muscular tone and strength of the stapedius and tensor tympani increase, so that the patient is again better able to properly adjust the receiving mechanism of the membrana tympani, and the ossicular chain, for the proper transmission of the sonorous vibrations. Tinnitus of aural origin generally decreases in intensity or entirely disappears. Sensations of numbness and fulness, neuralgic otalgias, etc., diminish or disappear. Obstinate otorrhea frequently ceases.

Zünd-Burguet thus tabulates his results in 528 cases, after one course of 50 treatments by himself according to the above method:

| Number of Cases | Hearing Distance Increased | Percentage |
|---|---|---|
| 44 | 12 times | 8.3 |
| 52 | 10 " | 9.9 |
| 48 | 8 " | 9.1 |
| 70 | 6 " | 13.3 |
| 68 | 5 " | 12.8 |
| 60 | 4 " | 11.4 |
| 84 | 3 " | 15.9 |
| 64 | 2 " | 12.1 |
| 38 | Less than 2 times | 7.2 |

In this series there were the following conditions:

| | |
|---|---|
| Otitis media catarrh. chron. (simple and mixed) and otosclerosis.. | 497 cases |
| Otitis media catarrh. chron. residualis | 12 cases |
| Otitis media purulenta chronica | 4 cases |
| Trauma of the perceptive apparatus | 1 case |

A. Raoult of Nancy, G. de Parrel of Paris, John Helsmoortel of Antwerp, and others report similar results.

27 West Sixty-eighth Street.

## CLINICAL OBSERVATIONS OF AUSCULTATION AT THE ACROMION PROCESS

By MAX GREENWALD, M.D.,

NEW YORK

ASSISTANT IN THE MEDICAL CLINIC OF THE N. Y. POST GRADUATE MEDICAL SCHOOL AND HOSPITAL; VISITING PHYSICIAN TO THE NORTHWESTERN DISPENSARY.

Acromial breathing was first described by Dr. Robert Abrahams in the *Archives of Diagnosis* for April, 1913: "When the bell of the stethoscope is placed over the acromion process with perfect adaptation to the bone and the patient is told to breathe, count, whisper, or cough, the sounds conveyed to the ear will be found to be greatly accentuated."

In my observations of many cases of incipient tuberculosis in the Medical Clinic of the N. Y. Post Graduate Medical School; the above method

has proved a valuable auscultatory sign. I dare say that resort to an *x*-ray examination in a large number of our so-called questionable cases will be found unnecessary in many instances with a proper interpretation of the acromial breathing sign.

Remembering that at the right apex normal breathing is bronchovesicular and that the whispered and spoken voice is louder than that heard at the left apex, we have a mental picture of the normal right apex in auscultation. It is here that the general practitioner not especially trained in diagnostic methods of incipient tuberculosis will encounter some difficulty.

The change from normal bronchovesicular breathing in a questionable case of right apex tuberculosis to the prolonged expiratory note of incipiency is not always well defined. The importance of acromial breathing here becomes apparent to one who has given this sign some study. Auscultation of the acromion process in this condition will show the breath sounds exaggerated in quality and sharply defined; the whispered voice will be heard louder and clearer. This sign will be found of some help in determining definitely the progress of the disease in its different stages.

Auscultation of the left apex normally reveals vesicular breathing and indistinct whispered voice. In early involvement of this apex, with only one or two auscultatory signs present, diagnosis is sometimes made difficult through musculature of patient, poor breathing, and other causes. Examination of the acromion end will here accentuate signs if present and help eliminate sound foreign to lung tissue.

Appreciating the significance of crepitant râles when heard at the end of inspiration, and the tendency to overlook this very important sign when not prominent, we can with some degree of certainty establish its presence or absence through the above-mentioned method.

While this sign was found to be present in a small number of cases of chronic bronchitis and probable healed tubercular processes this would not discount its value; breathing here when not forced would show little change, and the whispered sound and spoken voice were not influenced.

To summarize the advantages of this new sign:—

1. We auscultate over a fixed point eliminating anatomical peculiarities of the patient that may be present.

2. In right apex tuberculosis when the step from normal to incipient disease is not always easily elicited, a clearer transmission of sound will be obtained over the acromion process.

3. Râles can be found very often by acromial breathing sings that were not heard when examining the apex. This alone should give this method place in a routine examination of the apices for incipient tuberculosis when we consider that upon the presence of râles depends our determining the activity of a tubercular process.

4. It is a corroborative sign and should be made use of after first having examined the apices by the regular methods in use.

340 East Seventy-ninth Street.

**The Gastric Ferments in the Urine.**—Carlo Romagnolo has demonstrated the presence of a minute quantity of pepsin and rennin in the urine of normal individuals. These are either absent or greatly diminished in cases of carcinoma of the stomach. They are absent in cases of achylia gastrica. In pregnancy they are increased in amount. They are slightly increased in febrile conditions, and are diminished in states of cachexia.—*La Riforma Medica.*

## Medicolegal Notes.

**Practising Without a License—Officers of Corporations.**—In proceedings for practising without a license, it is held that an officer, employe, or agent of a corporation who practises medicine without a license commits an offense, though he purports to act for the corporation.—Norwood v. State, Texas Criminal Appeals, 158 S. W. 270.

**Privileged Communications — Waiver.** — In a personal injury action it appeared that the plaintiff was taken to the office of Dr. C., who dressed his wounds, which included an injury to his hand, and treated him for about three weeks. He then changed physicians and consulted Dr. M. He testified himself that Dr. C. took out a bone, and lanced his hand, which was festering, and Dr. M., as a witness for the plaintiff, testified that when the plaintiff came to his office his hand was very much swollen and infected. It was held that by introducing the evidence of Dr. M. the plaintiff had waived the right given to a patient by Missouri Rev. St. 1909, P. 362, to object to testimony by his physician as to information acquired in his professional character, so as to permit Dr. C. to contradict such evidence by testifying that when he stopped treating the plaintiff the hand was healing.—Oliver v. Aylor (Mo.), 158 S. W. 733.

**Malpractice—Opinion's Evidence—History of the Case—Insufficient Evidence.**—In an action for damages for alleged malpractice in mistakenly diagnosing and treating an ailment of the leg it was alleged that the defendant diagnosed the disease as blood poisoning, when in fact it was a disease of the leg "at the right tibia," which disease and ailment had well-known and peculiar signs and symptoms. The disease was not named, and it was not alleged wherein the treatment was wrong. It was held that the complaint was uncertain and not specific and subject to demurrer on the ground of uncertainty. Two physicians were called as expert witnesses to give their opinions based upon assumed facts and the "history of the case," which history of the case was material to their opinion. It was not within the personal knowledge of the expert witnesses, but had been obtained from conversations with the parents and friends of the plaintiff. It was held that their opinions had no value as proof. The defendant contended that it was necessary for the plaintiff to establish (1) that he had octeomyelitis at the time the defendant treated him; (2) that the defendant's mistaken diagnosis was due to negligence on his part; (3) that the treatment, judged by the proper legal standards, was improper, and that the injury resulted therefrom. It was held that, the opinions of the expert witnesses being eleminated, there was no evidence showing that the plaintiff was afflicted with osteomyelitis prior to the defendant's last visit to him. There was not sufficient evidence to show that the defendant carelessly and negligently treated the disease or that the disease was not blood poisoning or septicemia. It further appeared that osteomyelitis might develop from the septic condition due to septicemia, and that the presence of osteomyelitis on a date subsequent to the defendant's last visit to the plaintiff was not proof positive of its existence in the plaintiff's leg previous to the defendant's last visit. Judgment for the plaintiff was reversed.—Osborn v. Carey, Idaho Supreme Court, 133 Pac. 967.

## OPERATIVE TREATMENT OF THE GASTRIC CRISES OF TABES.

MAUCLAIRE (*Archiv. Gen. de Chir.*, Nov. 25, 1913) has given a very clear and concise résumé of the operative attempts to cure this condition, or at least afford some relief from the intense suffering experienced during these crises. He first calls attention briefly to the factors concerned in the production of gastric crises. The sensitive innervation of the stomach is furnished by the pneumogastrics and the sympathetics. Between these nerves and their branches there are countless anastomoses. The gastric path of conduction towards the center ascends from the stomach toward the posterior roots by passing through the splanchnic nerves, which spring from the thoracic ganglia, then by the communicating branches, by the intercostal nerves, by the posterior roots and their ganglia, and finally arrive at the cord, the center of the reflex pain. The initial cause of the gastric pains is a sensitive reflex starting from the gastric mucosa. But the point of departure of the painful sensitive reflex is perhaps also localizable at the level of the medullary roots themselves, or upon the meningeal root sheaths, or at the surface of the posterior columns. Many different suggestions for operative treatment to overcome these pains have been made and Mauclaire considers the most promising of these.

Regarding lumbar puncture he recalls that there was a great amelioration of the symptoms in one single case that has often been cited, that of M. Debove, while in another there was a grave syncope. Intraspinal anesthetic injections have been inadequate. The next four suggestions receive short adverse comment. Jaboulay, in 1900, suggested that the elongation of the solar plexus would be beneficial. Mauclaire cites seven instances in which this formidable operation was tried. In one case the patient was relieved for two years, in one for one month, and in the other five there was an immediate recurrence of the symptoms. Root resection was tried by Dana, Abbe (1889), Horsley, and others, but it was Foerster who recommended the methodical employment of intradural root resection in the treatment of Little's spastic paraplegia and the gastric crises of tabes. This operation has been done many times for Little's disease in America, but the early enthusiasm seems to be dying out, and the proposition to treat tabetics by root resection never gained much headway. Abroad the most extensive series is that of Foerster, which is summarized by Mauclaire as follows: "In 64 operations there were 6 operative deaths, plus 4 secondary deaths from urinary infection; 52 ameliorations, 2 negative results. There is, in fact, nearly 24 per cent. mortality. As for late results, among 47 patients re-examined one notes 29 cures without recurrences, 18 have had recurrences but less painful, while the other cases could not be followed up." Foerster says that it is necessary to resect at least seven roots between the fifth dorsal and second lumbar. Küttner had two deaths in thirty-two operations; von Eiselsberg none in eleven cases. In spite of these favorable statistics, Mauclaire thinks that the operation remains a very serious one, for certainly many of the failures have not been published. Guleke advised extradural rhizotomy in order to avoid injuring the arachnoid, thus preventing the escape of spinal fluid. Leriche tried this modification of Foerster's operation four times, finding it easy once and very difficult in the other three cases, while in two it was impossible because of abundant hemorrhages.

Regarding subdiaphragmatic resection of the pneumogastric, Mauclaire states that in two cases Exner did a gastrostomy in addition in order to avoid postoperative paralytic dilatation of the stomach, and also put a drain into the pylorus in order to avoid pyloric spasm. This resulted in one success and one failure; von Eiselsberg had two successes and one failure; Küttner had one failure. Exner himself, however, reports (*Zentralblatt für Chir.*, Dec. 27, 1913) that in the last nine cases, besides the subdiaphragmatic resection of the vagi, he has also done a gastroenterostomy with no deaths. He states that the mortality of Foerster's operation amounts to 12 to 15 per cent. and is thus appreciably greater than in vagus resection; that Foerster's operation gives failures and recurrences in about 40 per cent., and these percentages are about the same in his (Exner's) operation. Whether a special case may be suited for one or the other of these operations may be decided perhaps, under the circumstances, through the injection of novocain into the neighborhood of the spinal ganglia or atropine injection.

In one case, where the vomiting was so severe and incessant that the patient threatened to commit suicide if the operation was not done, Küttner did a two-stage intracranial resection of the left vagus. The patient appreciated the gravity of the operation and had made provision in advance for his funeral. This turned out to have been wise, for while there were no immediate serious symptoms either as to pulse or respiration, a fistula, with discharge of cerebrospinal fluid, appeared on the sixteenth day and this was soon followed by purulent meningitis and death. The interval between the first and second operations was eleven days, the patient dying three weeks after the preliminary craniectomy. Franke's operation (avulsion of the intercostal nerves and the medullated roots, the spinal ganglion and the communicating branches) calls to mind the avulsion of the nerves in the treatment of facial

neuralgia. In pulling upon the intercostal nerves he expected to act upon the communicating branches of the great sympathetic and upon the root ganglion. Twice out of three times the ganglion does come away with the nerve. It is necessary to resect in this way the third to the eleventh intercostal nerves in order to avoid the intestinal as well as gastric crises. The principal operative accident is the opening of the pleura. There are reports extant of eighteen cases operated upon by this method. There were three deaths, one two weeks after operation from purulent pleurisy, one forty-three hours after operation from shock (and unilateral pneumothorax); the third cannot be charged to the operation, since it was brought about by an intraspinal injection for the treatment of recurrent crises five months after operation. There were eight recurrences of gastric crises at periods varying from six weeks to a year. There were seven complete cures. It is evident that Franke's operation gives a good percentage of cures or ameliorations and that the death rate is much lower than in Foerster's operation; it would seem justifiable therefore to try this before doing the more serious root resection.

## THE CAUSE OF DIABETIC COMA.

A GREAT deal of controversy has arisen regarding the pathogenesis of diabetic coma. In spite of ample experimental and clinical evidence that this condition represents an intoxication by β-oxybutyric acid and its derivatives, there is still no consensus of opinion as to the actual rôle played by these substances. Klemperer and von Noorden advanced the view that certain unknown toxic products arising in diabetes act upon the brain, causing coma, and then act destructively on the protoplasm of the body as a whole, giving rise to β-oxybutyric acid. This substance, according to the theory of the above observers, is a result rather than a cause of diabetic intoxication and bears the same relation to the latter as it does to hunger and fever, in which it is also produced in fairly large amounts. The coma of anemia and of dyspepsia is also accompanied by the excretion in the urine of acetone and diacetic acid, and occasionally by β-oxybutyric acid. The last is sometimes excreted in uremia and hysteria, although coma may not be present.

Stadelman and others of the Naunyn school pointed to their investigations which seemed to show that diabetic coma is not the result of a specific acid intoxication but is to be attributed to the withdrawal of sodium from the organism. The good effect following the administration of sodium bicarbonate apparently confirmed this hypothesis. But within recent years a number of investigations carried out by Goldscheider and his pupils tended to discredit the above teaching. The latest attempt to solve this question was made by J. Masel, who died just as he completed his investigations. His article appears in the *Zeitschrift für klinische Medizin*, Vol. 79, Nos. 1 and 2.

From a review of the most recent work on this subject, Masel concludes that diabetic coma is a poisoning caused by β-oxybutyric acid, diacetic acid, and acetone which act chiefly upon the cerebrum and the respiratory and vasomotor centers, and produces both experimentally and clinically the symptom-complex of diabetic coma. In a series of observations made on animals subjected to experimental coma, and on diabetic individuals in the precomatose and comatose conditions, Masel noted that a real acid state of the blood, that is, an excess of the hydrogen ions over the hydroxyl ions, is not present in any of these states. On the other hand, in other conditions, particularly in narcosis, there is a pronounced excess in the amount of hydrogen ions. This shows that the relative diminution in the hydroxyl ions is not present in diabetic coma. Moreover, Masel studied different stages of diabetes and found that some patients with a pronounced degree of acidosis have the same hydroxyl content in their blood as normal individuals, even though they have not received any sodium for several days. Conversely, it was found that some individuals suffering from gout have even a smaller content of hydroxyl ions in the blood than diabetic individuals. The conclusion is drawn that the occasional reduction in the hydroxyl ions in diabetes is not a primary manifestation, but, occurring in consequence of the disturbed metabolic regulating mechanism, is to be regarded rather as a secondary manifestation, such as occurs during narcosis and in agonal conditions. The point is emphasized that the reduction in the hydroxyl ions is merely a relative one; there is no actual acidity in the reaction of the blood.

Masel concludes from his study of this subject that an acid intoxication or acidosis in the sense implied by Naunyn and Stadelman does not exist. There is no excess of free acids in the blood, β-oxybutyric and diacetic acids being present in the form of salts. These compounds therefore are responsible for diabetic coma which is not, according to the theory advanced by Masel, to be regarded as an acid intoxication.

## MEDICAL EDUCATION.

THE question of medical education is one that is attracting a good deal of attention just now, for it is generally recognized by those who are in the best position to judge, that all is not as it should be, so far as medical education is concerned in the United States and in Canada. Nor is the training which is given to medical students in Great Britain meeting with that full meed of approval which has been given to British methods of medical training in days gone by. Criticism of a severe kind has been directed against the British system recently by well-known members of the profession of Great Britain. All are practically agreed on one point, and that is that the curriculum of the medical student is too full. It is impossible for a man to digest and assimilate all the various subjects which make up his course. He may indeed pass searching examinations on these subjects but this is not to say that he really knows them, merely that he has crammed sufficiently to pass, while as a matter of fact he has only a bowing acquaintance with most of them. He has

perforce to specialize and consequently a great deal of his time has been wasted and probably his health injured by cramming subjects for which afterwards he will have little or no use. Even examinations are beginning to be regarded askance and indeed it may be doubted if a large number of severe examinations serve any useful purpose.

But the point chiefly in question now seems to be as to whether the German system of medical education or the English system is the best adapted for turning out the well-rounded practitioner and the specialist. Possibly the German system is the best from the scientific standpoint, but it is now argued in some quarters that it is also the best from the clinical point of view.

In the *Dominion Medical Monthly* for December, 1913, is published the presidential address delivered before the Academy of Medicine of Toronto by Dr. Herbert I. Hamilton which deals with medical education. Referring to the matter of clinical teaching the speaker noted that it had been suggested by some that the clinical teaching in Toronto hospitals should be in the German way, that is by professors who devote their whole time to this work, and undertake no private practice whatever, occupying a chair in the university and receiving adequate remuneration. Their work consists of teaching, setting examinations, and determining the qualifications for practice. In the opinion of Dr. Hamilton such an arrangement would be by no means ideal and he goes on to point out that while it is, of course, essential that the clinician should be thoroughly acquainted with theoretical medicine and hospital practice, it is at the same time highly desirable that his experience should not have brought him into contact with hospital patients only, but that he should have also had ample opportunities for coming into close contact with private patients and of thus acquiring the qualities which make for success in that line of work. It would be as easy, thinks Dr. Hamilton, to fit a square peg into a round hole as to find a man who has never himself personally had to deal with patients of this class, who is capable of imparting to the students the tact and intuition which are so essential in dealing with them.

It may, perhaps, be said that the British system of medical education tends to produce the most efficient general practitioners and the German system is calculated to turn out the best laboratory workers and possibly specialists. The former system is responsible for the best general practical results and the other system for the best theoretical results. Would it not be possible to evolve a system of medical education in which were to be found the best features of each system? It would seem that the solution of the problem lies in this direction and that thus an ideal system might be brought about.

## A Simple Treatment of Anthrax.

An important communication presented before the recent International Medical Congress was that in which Salvatore Gucciardello, Surgeon to the Hospital of Vittoria, Italy, described his rapid method of treating anthrax by means of live steam. The virtues of this method reside in its bloodless character and in the fact that it can be carried out with an improvised apparatus. Any kettle or vaporizer can be used, provided that it be fitted with a spout 2 cm. in diameter, bent in such a manner that the outer end points in a horizontal direction. Generally a temperature of 50° to 55° C. can be easily borne. The steam is directed upon the lesion and the normal parts that immediately surround it, the whole being enclosed within a cardboard cylinder, which serves to confine the action of the steam. The cardboard cylinder should be 30 to 40 cm. long, and may be held at a slight distance from the skin so that the steam may have ready egress. If the lesion of anthrax is on the neck or head, the latter should be wrapped in cold cloths, frequently renewed, in order to prevent cerebral congestion. From five to seven applications of the steam, of one hour each and at intervals of one and a half hours, may be given in the course of one day. During the intervals the sore part may be covered with gauze dipped in hot water. From the very beginning of the treatment the patient is said to experience its soothing effects. The pain diminishes, sleep becomes possible, and the temperature tends to subside. The extension of the disease process is stopped from the outset. The infected tissue becomes less hard, the characteristic sieved appearance becomes more marked, and a small amount of pus, together with other substances, exudes from the openings. No washing or irrigation of the parts is necessary. The fever ceases and every sign of infiltration about the lesion disappears in mild cases in from two to three days, and in the worst cases in from five to six days. In cases that have been subjected to the knife the vaporizing treatment effects a still speedier recovery. The author's experience comprised fifty cases. The good effects of the treatment are attributed to the great degree of heat to which the diseased part is subjected. The temperature of 50° to 55° C. at the surface, and of 42° to 48° in the interior of the lesion serves to destroy the anthrax bacillus and the secondarily invading staphylococcus. At the same time the vitality of the tissues and their resisting power are increased.

## Death of Goldmann.

A scientist barely known to the American medical public has just passed away at the age of fifty, and the Germans are mourning the loss of one who was coming to the front so rapidly that he might, had he lived, have become a Virchow, or greater. To anticipate, he was best known for his patient and triumphant work in staining living tissues. His contributions in this field would alone have made him famous. According to an appreciation in the *Münchener medizinische Wochenschrift*, No. 49, 1913, Goldmann was an odd example of a cosmopolite. He was born in Dutch South Africa of German parents. Under the English rule he grew up an intensely British subject, and all his life belonged to the Anglican Church. He was of the theological bias and throughout his brilliant medical and surgical career was always wishing himself a cleric. He returned to Germany with his parents and finished his medical studies at Freiburg, 1886. Proceeding to Frankfurt he mastered histology and pathology under Weigert; then surgery under Kraske. His work afterwards was chiefly in these fields. Some special influence, or perhaps lack of influence, always prevented his promotion as a teacher. He should have held a full chair at an early date, and have

risen rapidly, but his honors were so meager that he hardly regarded them. His work in pathology and surgery touched almost all great subjects and adorned them. He was only professor of surgery in a Diakonnissen Home in Freiburg but patients came to see him from all regions for surgical treatment, which he did not hesitate to style "the brutal art." As an operator he was excelled by no one. One of the greatest students of malignancy, he died of sarcoma of the eye. The sensation caused by his discovery of vital staining has not yet abated. Goldmann, with his religious bent had also a strong esthetic bias. He was unusually gifted in the arts and music.

## News of the Week.

**To Revoke the License of Drug Addicts.**—A bill drawn up by Dr. C. B. Towns of this city and now under consideration by the Senate Committee on Public Health, is designed to prevent the sale of all habit-forming drugs except under severe restrictions. One of the sections of special interest to physicians provides that "Any license heretofore issued to any physician, dentist, veterinarian, pharmacist or registered nurse may be revoked by the proper officers or boards having power to issue licenses to any of the foregoing upon proof that the licensee is addicted to the use of any habit-forming drugs, after giving such licensee reasonable notice and opportunity to be heard." If such a bill is to become a law it should state specifically what are "habit-forming drugs" and to what extent one may use them before being regarded as "addicted" to them. Alcohol and tobacco are habit-forming drugs.

**Health of the Canal Zone.**—For the months of October and November, 1913, the death rate among employees in the Canal Zone was 7.61 and 10.01 per thousand respectively, these figures representing a total of 37 deaths from all causes among employees in October and of 45 in November. For the entire population of Panama, Colon, and the Canal Zone the death rate during October was 25.33 per thousand, and during November 27.94. During the two months there were 11 deaths from tuberculosis, 5 from lobar pneumonia, 3 from malarial fever, and 35 from external violence. Smallpox is reported as prevalent in Lima and Callao, Peru, and the plagues as decidedly on the increase in Guayaquil. No case of the latter disease has reached the Isthmus, however, but one case of smallpox was removed from a vessel entering Balboa during the month of November, and was carefully isolated. No cases of yellow fever originated on or were brought to the Isthmus during the month. Surgeon John L. Phillips is the Acting Chief Sanitary Officer of the Isthmus.

**City Hospital Alumni Dine.**—The Society of the Alumni of the City Hospital, New York, held its annual dinner at the Hotel Royalton on January 21. The guest of honor was Michael J. Drummond, former Commissioner of Public Charities, to whom an album containing resolutions in commendation of his work was presented.

**Wisconsin Law Invalid.**—The so-called "eugenics law" recently passed in Wisconsin, which provided for the issuance of a marriage license only upon a certificate of good health, was declared to be unconstitutional in the Circuit Court on January 20. It was held that the law was of unreasonable salutary limitation in so far as the physician's fee was concerned, and that it was an unreasonable and material impairment of the right of proper persons to enter into matrimony. Although praised because of its aim toward the suppression of sex diseases, the law was condemned because its enforcement was a practical impossibility.

**Typhoid Fever Carriers.**—The annual report of the Medical Officer of the Local Government Board of London cites two cases of women, apparently healthy, who are carriers of typhoid bacilli. Sixty cases of the disease, of which six were fatal, were traced to one of the women. The situation was met by the allowance to each woman of a pension sufficient to support her and keep her from coming into contact with others.

**Smallpox at Niagara Falls.**—Every theater in Niagara Falls was ordered closed by the Board of Health on January 22, because of the prevalence of smallpox. Seventy-nine houses are under quarantine, many of the churches are closed, and twenty-nine patients are being cared for in the Quarantine Hospital.

**Another Typhus Ship.**—Among the passengers on the steamship *Kaiser Franz Josef I*, which arrived in New York on January 19, there was found one man suffering with typhus fever and another with suspicious symptoms. This was the third case of the disease to reach the Port of New York within the last two weeks. The Greek port of Patras seems to have been the course of infection of all the cases. The Health Officer ordered 149 of the steerage passengers removed from the ship to Swinburne Island, and the ship was then thoroughly disinfected.

**Low State Mortality.**—The death rate in New York State for 1913 was 14.9 per thousand of population, a very slight advance over the record rate of 14.8 per thousand for 1912. The total number of deaths for the year was 145,056. The most notable increase occurred in deaths reported as due to cancer, which numbered 8,525, as compared with 8,234 in 1911, and 7,500 in 1910. During the past five years the deaths from cancer have been 5.3 per cent. of the total mortality, while in 1892 they formed only 2.6 per cent. During 1913 there were only 89 deaths from tetanus and but one death from smallpox, the lowest figures reported in many years. Three cases of pellagra occurred in the State during the year, but none was fatal. As usual the death rate in the cities was lower than that in the rural districts.

**Vaccination Law Upheld.**—The Appellate Division of the Supreme Court of New York in a recent decision upheld the law covering the vaccination of school children. It was stated that parents must permit their children to be vaccinated in order to attend school, and that if they refuse they may be fined five dollars for a first, and fifty dollars or thirty days in jail for a second offence.

**The Government and Radium.**—During the last two weeks the Committee on Mines and Mining of the House of Representatives has been hearing arguments for and against the bill providing for the withdrawal from public entry of lands containing radium-bearing ores. Considerable opposition to the plan has developed among the people of Colorado as well as among those financially interested in the production of radium. Dr. Robert Abbe, Dr. Howard Kelly, and Dr. Harvey Gaylord were among those appearing before the committee in favor of the bill, and Mine Commissioner

Henahen of Colorado and others argued against it. At one of the hearings the statement was made that a wealthy man of philanthropic ideas who preferred to remain unknown was prepared to provide fifteen million dollars to be used for the erection, equipment, and maintenance of twenty radium institutes for the treatment of cancer throughout the country. No corroboration of the statement and no further details as to the identity of the supposed donor have been forthcoming.

**National Drug Fight.**—A State and National campaign against the promiscuous use and sale of cocaine and heroin has been started in New York, with the financial backing of Mrs. William K. Vanderbilt.

**Gift for Medical Education.**—The Medical Department of Washington University, St. Louis, recently received from the General Education Board a grant of $750,000, which is one-half of the amount which the University has been trying to raise for the benefit of its medical school. The money was given under the same conditions as attached to the gift to Johns Hopkins University a short time ago: that is, that the teachers in the departments benefited while free to give medical or surgical service of any kind, must do so without personal gain, and that practically their entire time must be devoted to hospital work, teaching, and research. The specific purpose of the gift is to create full time teaching and research departments in medicine, surgery, and pediatrics.

**Dr. Williams for State Health Department.**—Dr. Hermann M. Biggs, the new Commissioner of Health of New York State, on January 21 announced the selection of Dr. Linsly Rudd Williams as First Deputy Commissioner of Health. Dr. Williams has had large experience in public health work and is a member of the Metropolitan Sewage Commission, a director of the Association for Improving the Condition of the Poor, and a member of the Public Health Section of the New York Academy of Medicine. It is understood that Dr. Williams will accept the appointment.

**Physicians' Mutual Aid Association.**—The forty-fifth annual meeting of the Physicians' Mutual Aid Association of New York was held at the Academy of Medicine on January 20. One of the interesting items of the president's report was the announcement of a bequest from Dr. Charles A. McBurney of $1,000 to be added to the fund of the Association. Dr. McBurney's name was placed on the list of benefactors. The president also reported that the average age of new members was thirty-five years. The following officers were elected: *President*, Dr. W. F. Mittendorf; *Vice-Presidents*, Dr. W. C. Phillips and Dr. Joseph W. Ingalls; *Secretaries*, Dr. A. E. Davis and Dr. Edward S. Peck; *Corresponding Secretary*, Dr. W. B. Jennings; *Treasurer*, Dr. Daniel Lewis; *Trustees*, Dr. Samuel Lloyd, Dr. Edward H. Squibb, and Dr. Robert T. Morris.

**Friedmann Sanatorium Closes.**—The Lower Saranac Lake Health Resort at Saranac Lake, N. Y., which was opened last July as a place for the administration in the Adirondack region of the Friedmann treatment for tuberculosis, was closed recently. Its abandonment apparently marks one of the final stages in the exploitation of the treatment around New York.

**Value of an Eye.**—Damages to the amount of $8,500 were awarded by a jury in Philadelphia recently to a boy and his father for the loss of the boy's left eye. The suit was brought against the company operating a large iron foundry in Coatesville, Pa., where an explosion of dynamite destroyed the sight of the eye.

**Charitable Gifts.**—Mrs. William G. Warden of Philadelphia has offered to erect, as a memorial to her husband, a fully equipped home for nurses in connection with the Germantown Hospital and Dispensary, at a cost of $60,000.

The Mountainside Hospital of Montclair, N. J., has received a bequest of $1,000 by the will of the late John C. Williams of that city.

**Smallpox Among Refugees.**—Several cases of smallpox were discovered on January 23 among the Mexican soldiers and refugees at Fort Bliss, Tex., and wholesale vaccination was ordered.

**Metropolitan Sewage Commission.**—Having completed a plan for the disposal of the sewage that now pollutes the water of New York Harbor, the members of the Metropolitan Sewage Commission tendered their resignations to Mayor Mitchel on January 23. A brief report of the work done was submitted with the resignations, as a preliminary to the detailed report which will not be completed until April. The commission was appointed in 1906.

**Medical Society Elections.**—PHILADELPHIA MEDICAL CLUB.—At the annual meeting held on January 16 the following officers were elected for the ensuing year: *President*, Dr. Samuel D. Risley; *Vice-Presidents*, Dr. McCluney Radcliffe and Dr. John W. West; *Secretary*, Dr. William S. Wray; *Treasurer*, Dr. Lewis H. Adler, Jr.

MEDICAL ASSOCIATION OF THE GREATER CITY OF NEW YORK.—At the annual meeting held at the Academy on January 19, the following officers were elected for the ensuing year: *President*, Dr. Thomas H. Southworth; *Treasurer*, Dr. Isaac Hartshorne; *Chairman for the Borough of Manhattan*, Dr. Thomas Darlington; *Chairman for the Borough of Queens*, Dr. L. Edward Moss; *Member of the Council*, Dr. Frank Herbert Daniels.

GEORGIA MEDICAL SOCIETY.—*President*, Dr. Justin L. Jackson; *Vice-President*, Dr. Eugene R. Corson; *Secretary-Treasurer*, Dr. Victor H. Bassett; *Delegates to the Medical Association of Georgia*, Dr. George R. White and Dr. Thomas J. Charlton.

**Obituary Notes.**—Dr. JOHN BOWMAN, retired, of Millersburg, Pa., a graduate of the Jefferson Medical College, Philadelphia, in 1865, died at the home of his son, after a long illness, on January 31, aged 72 years.

Dr. HANSON L. RAYMOND of Vinal Haven, Me., a graduate of the Medical School of Maine, Portland, in 1894, died at his home after a long illness on January 9, aged 54 years.

Dr. JOSEPH B. THOMAS of Carthage, Mo., a graduate of the State University of Iowa College of Medicine, Iowa City, in 1883, died at a hospital in New Orleans, La., following an operation for intestinal ulcer, on January 6, aged 54 years.

Dr. JAMES DRYSDALE BALFOUR of London, Ont., a graduate of the Western University Medical Department, London, in 1887, associate professor of obstetrics and professor of pediatrics in the Western University, and formerly superintendent of the Victoria Hospital, London, died at his home from pneumonia, on January 7, aged 57 years.

Dr. RICHARD VAUX L. RAUB of Quarryville, Pa., a graduate of the University of Pennsylvania, Department of Medicine, in 1896, second resident physician at the Phoenixville Hospital, Phoenixville,

and a member of the Medical Society of the State of Pennsylvania and the Lancaster County Medical Society died at his home after a long illness on January 1, aged 41 years.

Dr. JEFFERSON DAVIS GOBER of Beaumont, Texas, a graduate of the Louisville Medical College, Louisville, Ky., in 1888, and a member of the State Medical Association of Texas and the Jefferson County Medical Society, died at his home after several months' illness on January 2, aged 53 years.

Dr. EDGAR PATTON MCCOLLUM of Greensboro, Ala., a graduate of the University of Alabama Medical Department, Mobile, in 1893, a member of the American Medical Association, the Medical Association of the State of Alabama, and the Hale County Medical Society, and former mayor of Greensboro, died at his home after a long illness on January 2, aged 41 years.

Dr. JAMES DALLAS CROOM of Maxton, N. C., a graduate of the Medical College of the State of South Carolina, Charleston, in 1876, a veteran of the Civil War, having served throughout in the Condeferate Army, and a member of the Medical Society of the State of North Carolina and the Robeson County Medical Society, died at his home on January 5, aged 69 years.

Dr. ERASTUS R. ELLIS of Detroit, Mich., a graduate of the Cleveland University of Medicine and Surgery, Cleveland, Ohio, in 1857, died at his home on January 7, aged 81 years.

Dr. JOHN WILEY HAGLER of Prattville, Ala., a graduate of the University of Alabama Medical Department, Mobile, in 1894, and a member of the Medical Association of the State of Alabama and the Autauga County Medical Society, died at the Williamson-Faulk Infirmary, Gadsden, from blood poisoning, after a short illness, on January 3, aged 44 years.

Dr. JAMES A. SEXTON of Harnett, N. C., a graduate of the University of Maryland, School of Medicine, Baltimore, in 1873, and a member of the Medical Society of the State of North Carolina and the Harnett County Medical Society, died at his home after a long illness on January 7.

Dr. DUNCAN MCALPINE of Grand Haven, Mich., a graduate of the Toronto School of Medicine, Toronto, Ont., in 1893, and a licentiate of the Royal College of Physicians, Edinburgh, 1894, died at his home on January 4, aged 43 years.

Dr. CLINTON HELM, retired, of Rockford, Ill., a graduate of the College of Physicians and Surgeons, Keokuk, Ia., in 1852, died recently at his home, aged 85 years.

Dr. GEORGE E. FULLER of Monson, Mass., a graduate of Georgetown University, School of Medicine, Washington, in 1865, and a member of the American Medical Association, the American Academy of Medicine, and the Massachusetts and Hampden District Medical Societies, died suddenly at his home on December 23, aged 75 years.

Dr. WILLIAM C. LANE of Cambridge, Mass., a graduate of the Howard University School of Medicine, Washington, in 1880, died at his home, after a long illness, on December 21, aged 59 years.

Dr. BENNO A. HOLLENBERG of New York, a graduate of the Memphis Hospital Medical College, Memphis, Tenn., in 1885, died at his home on January 1.

Dr. JOSEPH H. SCHENCK died at Wynnewood, Pa., on December 27 at the age of 66 years. He was graduated from Jefferson Medical College in the class of 1869.

## Correspondence.

### OUR LONDON LETTER.

(From Our Regular Correspondent.)

TROPICAL MEDICINE FUND—CHANGES IN ANIMAL TISSUES CAUSED BY X-RAYS—REPORT ON THE PNEUMONIA OF THE RAND MINES—BOOKS EXHIBITED AT MEDICAL SOCIETY.

LONDON, January 9, 1914.

THE fund raised for the London School of Tropical Medicine by Mr. Austin Chamberlain has been closed at £72,000. That is enough for immediate needs though it was hoped £100,000 would have been reached. Mr. Chamberlain has sent a letter to the contributors thanking them again and informing them of the manner in which he has disposed of the money. The new buildings have cost £15,000, which he hopes will not be considered an undue amount to spend on bricks and mortar. It has provided very efficient laboratories and sleeping rooms for a few students the need of which had been felt. Ten thousand pounds has been devoted to research—this is the amount bequeathed by Lord Wandsworth to Sir William Bennett, who placed it at the disposal of the school. Six thousand pounds has been invested for the income to provide beds for tropical cases in persons who cannot afford the special nursing and treatment which some tropical diseases require. The remainder has been invested in trustee securities and its income will be available for the general purposes of the school, including the provision of the best modern appliances, the general equipment, and maintenance in full efficiency of the laboratories and improvements that may be found necessary for the teaching staff.

On Monday evening Dr. Jean Clunet of Paris read a paper at the Middlesex Hospital on the "Histological Changes Produced by *X*-rays on Animal Tissues." The Roentgen Society was in full force to hear this contribution which had been eagerly anticipated and at the conclusion of the paper Dr. Barlow, the director of the cancer research department at the hospital, described it as marking a point in the history of radiation and of radiumtherapy.

Dr. Clunet opened with the statement that skin grows in progressive layers from below upwards and on reaching the surface is cast off in dead scales. On the other hand, he continued, in cancer of the skin the young cells do not submit to this ageing process but become active on their own account and multiply at the expense of the organism. The effect of *x*-rays is to hasten the normal cell-ageing process—the cells exposed to the rays passing more rapidly through the several stages to their death, the speed varying with the strength of the application so that all the layers may be simultaneously hurried into dead scales or under milder doses only become thin and atrophied. In the former case an ulcer is produced. By repeating mild applications hypertrophy is produced.

Dr. Clunet went on to explain that under the strong rays the cells of the skin were stimulated to age so quickly that death took place before they could reproduce new cells. Under milder applications a proportion of the cells was aged, but a sufficient number remained unaffected or retained vitality enough to maintain the atrophied thin, "glassy" skin. Very small mild doses had a stimulating effect on the cells resulting in more active growth and even increasing reproduction. When

strong doses were applied to skin cancers—epitheliomata and rodent ulcers—the ageing seemed to be produced *en masse*, the deadly reproductiveness was destroyed, the cells carried on rapidly to their death in scales—harmless to the organism.

Again, the minute doses to which operators with radium were subjected stimulated the cells enough to cause overgrowth and even inflammation of the skin. In some cases actual cancer supervened. These *x*-ray cancers are extremely difficult to heal. Dr. Clunet said that in one case, acting on the principle he had enumerated, that strong doses destroyed growth, he tried full applications. The effect was favorable, but the nerves became involved and the treatment on that account had to be abandoned.

The report of the inquiry into the pneumonia which affects the laborers and in particular the tropical native laborers in the Rand mines, which was undertaken by Sir A. E. Wright in association with Drs. Parry Morgan, L. Colebrook, and R. W. Dodgson has now been published in full. You will remember that portions have previously appeared and that the inquiry was undertaken for the Witwatersrand Native Labor Association. The report deals in a thorough manner with the causation, prevention, and treatment of the disease. As you may have anticipated, the account of the employment of vaccines by inoculation is the most interesting part and is the last word on this mode of treatment which is recommended as a precautionary measure for every native before commencing work on the Rand.

The culture medium for the pneumococcus vaccines at first employed by the authors contained 1 per cent. of peptone and 1 per cent. of lemco with 2½ to 5 per cent. of human serum and an amount of alkali fixed by neutralizing to phenolphthalein, then adding 6 c.c. of normal acid solution to each liter of medium. Later they added up to 1 per cent. of glucose.

The experiments undertaken for this report are carefully described and the available statistical evidence considered. Some mass-experiments as to prophylactic inoculation showed a striking diminution in the number of cases for the first two months but after that period the preventive virus seems to have lost its effect as such. The question of therapeusis has to be answered in quite a different manner. It is not recommended generally but as a subject of further research with properly controlled experiments *en masse*.

After four months from the inoculation on recruiting it is recommended that the native laborer should be reinoculated, the dose each time, a thousand millions of pneumonia bacilli, cultivated on the glucose blood broth.

A special object of further research is suggested to try and determine whether 1000 millions is the optimum dose. Further a mass experiment is proposed in which each patient should be given at the outset of his attack a dose of 500 millions.

Other measures which may be taken are (1) for avoiding correction of infection, (2) for holding off influences which might impair the normal resistance of natives to infection. As to the first early detection, isolation, disinfection, ventilation, and quarantine are considered, each of which may have some influence; but it is held that on the Rand their effect will be doubtful on account of the difficulty of carrying them out, the many varieties of pneumococcus, and the fact that the bacillus is found living in a majority of healthy men.

Concerning the influences referred to in the second place, *e.g.* provision for changing houses to safeguard the natives from chills and similar measures their place in a plan of campaign against pneumonia is looked upon as quite subordinate. The report insists that the predisposing moment in pneumonia is not in incidental, temporary impairments of resisting power connected with mining work, but in the abiding defect of that power which is normal in the natives.

Last evening there was an assembly of bookworms in the rooms of the Medical Society of London for some of the treasures of its library were exhibited and the librarian, Mr. Bethell, discussed the origin of the society and the early working of its library. He drew attention to the manuscript diary of Dr. John Ward which he thinks of getting published; among the entries is one referring the death of Shakespeare to a merry meeting with Drayton and Ben Jonson, "of a feavor there contracted." Another manuscript supposed to be in Mead's handwriting relates to the appointment of an under library keeper who "shall at least understand Latin and Greek, also ye modern languages, if such a one can be procured." He is to take care that the library "be kept clean and neat by having it swept, ye windows and seats dusted down, and when necessary ye floors washt, and at least once a quarter all the books and shelves be cleaned." To help in this the college will allow him 10 shillings a quarter for an assistant. But he is himself to make a catalogue of the books, a list of donations, and to see that no candle be brought into the library. For all this the salary was to be £20 and no more. One of the most interesting volumes exhibited was the "De Trinitate Divini" of Servetus containing, it is said, the anticipation of the circulation of the blood some eighty years before the announcement of Harvey.

2. Measured Feeding for Older Children. W. B. P. Emerson.
3. Leprosy—Some Notes and Suggestions. J. A. Honeij.
4. Institutional Dentistry: Methods; Results. Report No. 2 F. A. Keyes.

1. **Study of Cancer.**—S. W. Little states that the theory that the internal secretions have direct normal physiological relations with each other in the sense of aids or antagonists does not appeal to him. On the contrary, the theory that each secretion is independent of all the others except in the sense that each is essential to the whole organism and therefore to the working of the others does seem reasonable. All those internal secretions of which we have accurate knowledge do affect tissues of widely different origins, but it is just as easy to understand how that is possible indirectly as directly and far more rational. With this idea as a basis many nutritional diseases at once assume a different aspect and a hopeful instead of a hopeless. In studying various diseases of faulty metabolism it suddenly occurred to the writer that cancer is absolutely and essentially such a disease, and at once many things became clear. In the production of cancer there must be some factor other than failure of some ductless gland or glands and trauma. Little believes the explanation to be either one or both of two events. In the first place it seems highly probable that cancer always occurs at the site of cell injury for the following reasons: 1. Cancer certainly does occur often at the site of a known injury. 2. Organs which are most protected

from injury are the rarest seats of cancer. 3. Organs which are most exposed to injury are the commonest seats of cancer, with one enlightening exception, the skin. 4. The skin. But even here, remember that skin cancer is commoner by far in men than in women; men are more exposed to skin injuries than women. The reason why cancer of the skin is rare in spite of frequent injury will appear later. 5. Even those organs, apparently well protected, which occasionally are the seat of cancer may conceivably be injured, *e.g.* the kidney by stone and the liver ducts similarly. Also it is confirmatory of the idea that cancer of the gall-bladder and the ducts is far commoner than of the liver itself.

3. **Leprosy.**—Honeij as a result of investigations on leprosy concludes as follows: 1. When the disease is advanced the patient's health varies daily; he feels exceptionally well one day and the next presents every symptom and appearance of a seriously sick person. 2. In comparison to the severe symptoms and general appearance of the patient, physical examination will reveal nothing. Lungs and abdomen are normal, and with the exception of a soft systolic murmur over the precordia, the heart is normal. 3. During eruption the skin is usually hot and dry. 4. Extreme mental depression at irregular intervals and nervousness are characteristic of every case. 5. Ulcers may heal rapidly and continually, or, as is seen in one or two cases, they become chronic and refuse to respond to treatment. Medicinal treatment varies in each case; in leprosy this fact is particularly accentuated. 6. The clinical symptoms of leprosy, although somewhat confused and often indefinite, are nevertheless correct symptoms of the disease and in the care and treatment of leprosy patients, are to be carefully observed and seriously considered. The consideration of the pulse, temperature and blood are so important and instructive, that a more careful study is being made and will, in all probability be reported in the future.

10. Standardization of Brains. R. Alexander-Bowers.

**1. Hypertonicity and Hypotonicity of the Vagus.**—J. C. Hemmeter in investigating the hypertonicity and hypotonicity of the vagus and the sympathetic nervous system concludes with regard to organ neuroses that increased excitability of the vegetative nervous system may give rise to organ neuroses. These may be brought about by two conditions, either the overexcitability of the nerves supplying the organ, or a morbid condition in the organ itself rendering it more reactive. In this way we can conceive of the origin of gastric, intestinal, sexual, heart and respiratory neuroses. But no one has as yet thought of conceiving neuroses of internal glands under this neurochemical viewpoint. Another factor which enters into this aspect of the etiology of organ neuroses, and which might be added to the two already defined, is what might be called "psychic pathbreaking," by which is meant the facility with which neurochemical influences are made to go in one definite direction to a certain organ because the individual has his or her attention concentrated upon that organ. We have, therefore, three conditions in the development of organ neuroses: First, a heightened nerve excitability; second, increased reactive power of the organ of response, and third, psychic facilitation by the attention. It is evident in considering the dissociation of neurotropic substances that those organs which are most readily and most easily appealed to are in the foreground with their effects. Patients that are already stomach sufferers will predominately react to epinephrine and pilocarpine by gastric symptoms. Asthmatic patients will react to very small doses of pilocarpine with profuse bronchial secretion. Hemmeter also emphasized in this connection, that the three states, increased excitability, increased reactive power of the organs, and increased psychic facilitation, may, one and all, be affected in the same or opposite direction. They may be inhibited, and therefore we may have organs of a lessened responsive power. All this goes to show the immense complexity of the problem of pharmacodynamic and physiological parallels in the antonomic and sympathetic nervous system.

**7. Periodic Explosive Toxemia.**—B. B. Crohn reports three cases of this nature and after pointing out that it is essential to find a fundamental cause for these cases as a group states that he is inclined to agree with those who have held it before, that the entire group represents a reaction to toxins gradually accumulating in the intestinal tract due either to abnormal intestinal bacteria or to ferment activity. The transition from the mild cases of intestinal autointoxication, characterized by languor and headache, to the group with periodical outbreaks of headache, vomiting, prostration, and even jaundice is a gradual one; a transition of degree rather than of kind; the same case only in a different bed; the same fundamental pathology, but, in the words of the evolutionist, "a variation from type in a single species."

**9. Institutional Treatment of Drug Addiction.**—C. J. Douglas after twenty years' experience is prepared to say that there is no chronic disease known to medicine that is more surely curable than morphinism, and curable, too, without the suffering supposed to be necessary. He suggests three principal requisites in the successful treatment of any form of drug enslavement: First, a physician who is familiar with the pathological condition of these cases, and who has had experience in their care and treatment; second, an institution where patients can be under the constant care of physicians and nurses; third, a method of treatment that provides for the individual study of patients and the adaptation of therapeutic means to the peculiar condition of each. The various forms of drug addictions, whether based upon opium or alcohol, constitute a cluster of diseases that deserve careful study and classification. Our best medical men should devote more attention to the subject, and take it out of the hands of quacks and semi-quacks and the vendors of infallible specifics. The serious character and wide prevalence of these ailments entitle them to this much consideration.

2. **Treatment of Tabes and Paresis.**—W. H. Hough says that in the treatment of nervous syphilis in its earlier stages, all authorities are now agreed that mercury and salvarsan are the most efficacious remedies. In the later manifestations, however, such as paresis and tabes, which have been shown to be active syphilitic conditions, treatment has not been so generally successful. Salvarsan seems to have a greater predilection for most of the other tissues of the body than it has for nerve tissues, which may explain some of the non-success. It has been shown that the blood-serum of recently treated or cured syphilitics has a marked trophic action on the specific spirochete and the following technique has been devised by Swift and Ellis for bringing an effective medical agent into immediate contact with the diseased process without incurring the danger of direct infection of salvarsan into the subarachnoid space. A dose, generally the maximum of salvarsan or neosalvarsan is given intravenously in the usual manner. At the end of an hour from 50 to 60 c.c. of the patient's blood are drawn by means of venous puncture, clear serum is separated, diluted to 40 per cent. with normal salt solution heated to 132.8° F. for half an hour, kept cool until the following day, then warmed to body temperature and injected into the subarachnoid space by means of lumbar puncture after the withdrawal of about 15 c.c. of spinal fluid, the amount of diluted serum injected being 30 c.c. After the first few injections if well tolerated 40 c.c. of a 50 per cent. serum is usually injected. It must be injected slowly without much pressure. After the injection the patient is kept in bed for about twenty-four hours with head covered. The number of treatments varies with the case, but the general rule is to give eight or ten treatments, one every second week and then discontinue them for a time, repeating, if necessary, and using as indices the Wassermann test with the blood and spinal fluid and the cell and protein estimations of the latter. Hough gives a brief summary of the cases of tabes in which he has tried this mode of treatment. The general opinion of those who have tried the method is that it is the most promising one for tabes and paresis that has yet been devised.

3. **Autoserosalvarsan Treatment of Syphilis.**—G. W. McCaskey draws attention to the fact that the discovery of the syphilitic origin of tabes and general paralysis has served to clear up the pathology of these diseases and that one factor of their intractability to antisyphilitic treatment is probably the inaccessibility of the subarachnoid lymph-space. He points out that salvarsan introduced intravenously does not enter the cerebrospinal fluid, as shown by positive Wassermann in spinal fluid while the blood test is negative. He describes the technique of intraspinal injection of autosalvarsanized blood serum which was introduced by Swift and Ellis of the Rockefeller Institute and reports on the results of this method as used by him in seven cases. He states that in twenty treatments administered over a period of three months he has seen remarkable improvement in some cases and he is of the opinion that the method in careful hands, when properly administered, is devoid of danger and offers a new and rational treatment in cases of cerebrospinal syphilis.

13. **Nitroglycerin.**—G. G. Ebright quotes from an article as well as from a private communication by Dr. George E. Laws with respect to the maniacal excitement occasionally produced among those engaged in the manufacture of nitroglycerin and also as to its aphrodisiac effect and the well known facts regarding its physiological action. Observations of the working conditions among the employees of the Dupont Powder Company at Hercules, Cal., showed that occasionally a workman was found who was immune to the action of the drug, but this was a very rare exception and the degree of the exposure required to produce the characteristic headaches varied with the individual, with the weather, and the length of time that the person had been in contact with the drug. A new man was very susceptible and warm weather aggravated the symptoms. After three or four days a considerable degree of immunity was produced, but the symptoms might still appear from extended exposure. The immunity was, however, rapidly lost and the absence from work for even two days was sufficient to effect this. It is a common practice among the workmen to place some nitroglycerin on their hat bands during periods of absence in order to maintain immunity. A characteristic symptom is a throbbing headache; this is often so severe as to cause loss of sleep, but the author had not observed maniacal attacks in his investigation. Permanent effects appear to be lacking. The general health of the workmen was uniformly fairly good and there were no evidences of destructive blood changes. Alcohol aggravates the symptoms by relaxing the blood-vessels. A case illustrating this feature came under his notice. A foreman of an excavating gang handled a large quantity of dynamite and following advice took some whisky to relieve symptoms produced; the result was an attack of homicidal mania. No evidences of a nitroglycerin habit had been noticed. The natural dread the workers in nitroglycerin have of the headaches precludes any likelihood of the acquiring of a pernicious habit. As far as the limited number of cases afforded an opportunity to judge, there was no evidence of any cardiovascular changes of importance and long continuance at the occupation seems compatible with good health.

14. **Oxycephaly.**—I. F. Stein reports a case of oxycephaly, steeple head. A Roumanian Jewess with this deformity came for treatment for cardiac trouble. According to Stein early and rapid blindness is a frequent accompaniment of the condition, but it has not occurred in the case reported. The shape of the head, prominence and size of the eyes, slightly deviated nose, high arched palate, intense headaches, nervous fits, which were ascribed to hysteria by former medical attendants, and characteristic dimpling of the inner table of the skull as shown in the roentgenogram, establish the diagnosis of oxycephaly in this case. In Stein's case the intelligence was not impaired.

11. Fracture of the Skull. The Roentgen Ray as an Aid in Its Diagnosis. W. H. Luckett and W. H. Stewart.
12. The Operative Treatment of Fracture of the Olecranon. A. W. Shea.

1. **Treatment of Fractures.**—E. P. Magruder compares the open and closed methods of treating fractures to the disadvantage of the former. He concludes that the closed method is the method of choice even when an approximate coaptation can be secured. On the

other hand, operation is indicated in the closed fracture of wide displacement and when correct apposition is otherwise impossible. Provided hospital facilities can be obtained operation is indicated in articular fractures when ankylosis threatens, and the best results are obtained after exact coaptation and suturing of the fragments. When operation is indicated at all, the earliest operation is the best. The operative treatment for open fractures is that which most nearly reduces them to the type of the closed fracture, except as to drainage.

2. **Experience of Open Fractures.**—E. S. Van Duyn gives his experience of twelve years in the open treatment of simple fractures at the Hospital of the Good Shepherd, Syracuse, N. Y., and concludes as follows: We hold that the open treatment of fractures is more scientific and gives more satisfactory results than the older method in those cases where complete reduction cannot be immediately accomplished and maintained; that the dangers of open treatment lie only in faulty technique; that excepting where it is necessary to bridge in a gap, foreign material other than sutures should not be introduced; that when such foreign material is necessary bone from the patient himself is best; that all cases should be examined at regular intervals with the *x*-ray to determine the amount and extent of callous formation, and when failure in such formation is manifest in spite of early manipulation strain pressure and massage should be employed.

4. **Metal Bone Plating a Factor in Non-Union.**—W. M. Brickner, among other deductions drawn from his own experience against the use of metal bone plating, gives the following: A metal plate screwed to a fractured bone can of itself cause delayed union and nonunion. Neither a 3⅝ metal plate nor an additional well applied plaster cast can be depended upon to maintain the alignment of a fractured femur shaft in a very muscular thigh.

5. **The Inlay Bone Graft.**—F. H. Albee reports bone graft in fifteen cases of pseudoarthritis, bony union in every case, and concludes that in the repair of deformity and the result of traumatism of the skeleton the advantage of the use of its own material and of the avoidance of seemingly necessary foreign substances has been clearly demonstrated. Metal introduced into the tissues is in most respects the direct antithesis of the bone graft. It favors infection, absorption, and disintegration of tissue.

1. **Prophylactic Inoculation Against Pneumococcus Infections.**—Sir Almroth Wright and coworkers from an extended trial of prophylactic inoculation against pneumonia, record in every case in which pneumococcal vaccine was used a reduction in the incidence rate and death rate from pneumonia. In adjudicating upon a procedure of prophylactic inoculation the following general theses must be taken into account: 1. The advantage derivable from a prophylactic inoculation will be limited by the patient's power of immunizing response. 2. The advantage derivable from prophylactic inoculation will depend upon the degree to which the population to which it is to be applied has already run the gauntlet of the particular microbe infection in question. 3. Where in comparative statistics we find that the difference between the inoculated and the uninoculated is after a time effaced, this does not necessarily indicate that the immunity of the inoculated is diminishing. 4. Comparative statistics furnish only a very incomplete account of the profit earned by any successful prophylactic inoculation. Among the recommendations put forward by the authors of the paper are these: In connection with prophylactic inoculation the task of research should be to obtain confirmation of the conclusion that we have in 1,000 millions the optimum dose for prophylactic purposes. It would also be well to make certain that reinoculation after a period of four months is really required. In connection with therapeutic inoculation the first task of research should be to institute a mass-experiment in which one large dose of vaccine should be given to the patient at the outset of his pneumonia attack. It is suggested that a dose of 500 millions might be tentatively employed in such an experiment, and that in such an experiment every alternate patient should be taken for a control.

3. **Studies on Growth.**—C. Funk early in 1913 pointed out that the results of the investigations of numerous students as to growth, together with the gain in our knowledge as regards the vitamines, now important constituents of our normal dietary, cannot fail to produce some effect on the investigation of cancer. Lately Funk succeeded in arresting the normal growth of young chickens, for the first time, on a diet containing vitamines. Here was a new hope for influencing the tumor growth without danger of producing a deficiency disease. He therefore inoculated chickens arrested in growth with Rous' sarcoma, a very virulent chicken tumor which takes in nearly 100 per cent. The result was that the tumor grew undoubtedly more slowly and was smaller in size than in controls on normal diet. The experiments described must be considered as a series of orientation experiments in an endeavor to influence tumor growth by diet. At present they do not admit of a practical application, but they suggest that, especially in cases of a quickly growing but not very malignant tumor, such a diet might have some slight inhibitory effect on the rate of tumor growth without producing a deficiency disease.

5. **Treatment of Sciatica.**—J. J. Grace reports the results of the treatment of sciatica by the use of the 500 candle-power lamp and static electricity. He gives the history of six cases successfully treated in this manner and states that he cannot feel any doubt but that, in addition to the local effects, general metabolic effects of a beneficial character are taking place in the organism from the employment of the static wave current.

1. **Radium and Cancer.**—A. P. Gould points out that the selective power of radium, enables us to use it to remove the cells of a malignant growth and to leave behind the healthy tissue. The true therapeutic use of radium rests upon its selective affinity for cancer cells and not upon a general caustic or destructive power. A list of cases of cancer successfully treated by radium is given and Gould emphasizes the point that these cases show the much more rapid and satisfactory effects of radium when introduced into a tumor than when it is applied as a plate on the surface of the body. The question is whether after operating for cancer we ought to use radium as a prophylactic measure to prevent recurrence. Gould does not see his way to do this. In the first place, we do not know where the supposed cancer cells are lurking and, as he said before, we have at present no clear evidence that the selective effect of radium on cancer cells is exercised over a wide area. But we do know that radium can produce such active cell growth as will end in cancer. His own experience warrants him in saying that in radium we have an agent that in many cases can be used in the treatment of cancer with great hope of success, and that the selective action upon cancer marks it out from all other known remedies for this disease; but this same experience also shows that it would be a gross exaggeration to speak glibly of radium as the "cure for cancer" in the sense that it will deal with any and every case of this disease. Such is not the case, but remembering what he started as a preface to this paper, that on the one hand the nature of cancer is unknown and most variable in its manifestations, and, on the other hand, that radium is almost the youngest of the known chemical elements, and has been studied but for a few years and by relatively few investigators, there is good ground for hope that in the time, which will surely come, when we shall unravel the secret of the nature of cancer and know more of the properties of radium, and how to use them better and to control them, we shall have a great extension of the therapeutic value of radium in cancer.

2. **Triple Syndrome in Abdominal Emergencies.**—Rutherford Morison draws attention to the importance of "The triple syndrome in abdominal emergencies." The principle of the law has been to some extent recognized for cases of appendicitis, for which a "lethal interval," "the dangerous remission," "the deceptive calm," etc., have been described and emphasized in many papers, but what is true of appendicitis is true for other abdominal emergencies. In all there should be three phases or stages which are as follows: (1) The stage of shock. (2) The stage of reaction. (3) The stage peculiar to each lesion. In all the dangerous lesions pain is severe enough in the first stage to produce symptoms of shock, varying from a feeling that something serious has happened, accompanied by pallor, sweating, and feebleness, to such a bad sensation and symptoms as to threaten and rarely to cause death. This is the period to which he is anxious to draw attention because it is of the greatest importance. If looked at fair and square it is difficult to miss the meaning of the symptoms but there may be only a single chance, the first look, the first visit. Half an hour, even a few minutes later, the second phase, that of reaction, has set in and in a short time the patient may be apparently so well that it is now almost impossible to believe that any dangerous condition is present. This is the time when mistakes are made. Morison thinks that the time has come to make a rule that all cases of abdominal injury and of acute abdominal pain should be sent to a hospital without delay for observation.

7. **An Address on Pneumonia.**—After referring to the incidence of pneumonia the influences of race, sex, and age upon its causation and its etiology Sir James Barr has this to say regarding its prevention: Any septic condition of the mouth increases the virulence of the pathogenic organisms, and so a foul-mouthed individual is usually a greater danger to himself than to others. The mouth should always be kept perfectly clean and as aseptic as possible and the teeth in good order. The nasal passages and throat should be kept clean with some simple oily preparation, such as pure liquid paraffin, as they are frequently the paths of infection for pneumonia, rheumatic fever, influenza, diphtheria and cerebrospinal fever. In the treatment of pneumonia he is in favor of the injection of pneumococcal vaccine and is absolutely opposed to the administration of phenacetin, antifebrin, and other coal tar products. Indications for treatment of cardiac failure are, 1. To lower the temperature and control the inflammatory process at the earliest possible period, before stagnation of the blood and hepatization have taken place, and thus preserve as far as possible the integrity of the respiratory apparatus; this also lessens the risk of involvement of the nutritive vessels of the lungs; 2. To maintain fair systemic blood pressure; 3. To keep the respiratory pump acting by lessening the frequency and increasing the depth of the respirations; 4. Remedies to lessen the toxemia and maintain the tone of the cardiac muscles; 5. Methods to lessen the spread of the mischief. In order to limit the spread of the disease the administration of lime salts is recommended. In the acute stages of pneumonia the more scanty and more sticky the expectoration, the more viscous the blood, the more lime salts and leucocytes it contains the more favorable the prognosis; on the other hand, the more fluid and hemorrhagic the expectoration, the more liquid the blood, the less the lime salts and leucoctyes, the worse the prognosis. Pneumonia should always be regarded as a serious disease; no matter how mild the case may at first appear, you cannot always forecast how it may develop, and every medical man in dealing with this affection should feel the responsibility of a human life in his hands. It has been said that young men kill their patients and old men allow them to die, but Sir James points out that early recognition and prompt treatment in all cases of pneumonia will save many a valuable life.

11. **Guaiacol in Pulmonary Tuberculosis.**—G. H. Mayberry is of the opinion that guaiacol is not used nearly so much in pulmonary tuberculosis as it might be. It has no doubt been used by a considerable number of practitioners, but abandoned as of little use, 1. It was not given in large enough doses; 2. It was not continued for a sufficiently long time; 3. It may not have been possible for the drug to be administered regularly. Even intervals of a few days in the administration have a prejudicial effect. Mayberry gives records of several cases in which he administered guaiacol in the manner stated above with conspicuously successful results.

## Berliner klinische Wochenschrift.

*December 29, 1913, and January 5, 1914.*

**Ozena an Infectious and Contagious Disease.**—Dr. Perez of Argentina presented his well-known views on this subject before the Berlin Laryngological Society upon the invitation of Professor Killian. Perez is easily the first authority on this subject and seems to have devoted most of his activities to it. His theories of its origin and nature have not been disproved. He points out the familial character of the disease, as when the condition exists in a mother and several

children. It is only necessary to find a microorganism to make this familial incidence a matter of contagion. Two germs accused here have been the Lowenberg-Abel coccobacillus and the Friedlander pneumobacillus. The author, dissatisfied with his results, then resolved to study the entire flora of the nasal passages, which comprise a dozen microorganisms, mostly familiar to all. In only one, the coccobacillus fetidus ozenæ, was there pathogenicity found in respect to ozena. This germ long ago received the name of bacillus Perez. The various tests by which this germ has been shown approximately to be the sole cause of ozena are now well known. The bacillus is able to enter the bloodstream and attack the nasal chambers as well as to act locally. Through his experiments Perez has demonstrated that ozena *per se* is the same radically as chronic atrophic rhinitis. The latter is a chronic coryza with little or no atrophy; but its apparent mildness does not prevent a good proportion of its victims from having the true ozenous qualities—the crusting and stench. The severer type is characterized by extreme atrophy and deformity (saddle nose). Perez's work depends as much as anything also upon his following up case after case, in which there were two or more people in prolonged intimate contact. The number followed up in this manner is very large and each case has been tested bacteriologically. Dogs have been known to act as carriers and hosts, and the coccobacillus Perez is a normal denizen of the dog's nasal chambers. The author has collected a very large number of such cases of apparent canine contagion.

**Etiology of Genuine Ozena.**—Hofer spoke after Perez on the same subject, and announced that he had followed the South American's lead in making the same tests upon German material. There have already been those who have believed the disease infectious, as shown, by efforts to trace it to tuberculosis or syphilis. In regard to Perez's bacillus, they were able to find it in the majority of cases. The difficulties of isolation were very great. When cultures were injected intravenously into dogs, the amount of germs in the nose was augmented, but this phenomenon was not always constant. Pure cultures of the coccobacillus gave off the characteristic odor, which is also very perceptible in mixed cultures. The dog can be directly inoculated in the nose. Next in order comes a word on other noses which in shape resemble the nose of severe ozena. Here belong various types of syphilis, which produce the extreme type of saddle nose. The atrophy may be chiefly responsible for the crusting, but however the latter arises, the greater the crusting the stronger the odor. The fetor which comes from diseased nasal sinuses, while penetrating, is quite unlike that of true ozena. Syphilis, according to its severity, destroys more or less of the nasal framework and produces a saddle nose, which is deeper than the mild degree seen in ozena. The latter has always been regarded as incurable, so that at best a victim can learn only to live with it. Hofer, after accepting all or nearly all of Perez's dicta, believes that there is possible cure through active immunization by means of a serum made from Perez's germ. If the response to treatment by means of this serum were favorable, it would furnish the last and most convincing link of proof of the assumed etiology of ozena.

**Paradidymitis Erotica Acuta.**—Heller describes a condition which has never received the attention it deserves, and the connection of which with the sexual life is not regarded as a direct one. It plays a part in determining whether or not continence is injurious. That it appears after suppression of frequent intercourse is admitted, also that it disappears at once after the resumption of sexual relations. But the question of a rapid relief of a turgid condition may be dealt with in a twofold manner. The seat of the trouble is not an active part of the genital apparatus; and turgescence should occur in the organs which participate actively in coitus—notably the testicles, seminal vesicles and prostate. Now the direct results of abstinence or continence, is as is well known, nocturnal emissions. The question is properly asked whether the men who suffer from "paradidymitis erotica" have not previously suffered from gonorrheal epididymitis. In 1891 Porosz described it under the term "bridegroom pains" by which he referred to certain phenomena caused by the almost continuous turgescence of the genitals. This expressed itself at times as a swelling in both epididymi, circumscribed and firm to the touch, which passes off in 24 hours. In a more severe type a true epididymitis develops, confining the patient to bed for days. This condition does not result from mere abstinence but from the almost continuous contact shortly before the wedding period with his wife to be. Cases have been reported in which sexual incapacity for coitus, swollen epididymi, nocturnal pollutions, and sexual neurasthenia occurred side by side. Hence abstinence as a result of impotence may act like voluntary restraint in producing the epididymal lesions. Wälsch has described a sympathetic, erotic epididymitis which he ascribes to an acute hyperemia. In one case the patient had been through a gonorrheal epididymo-orchitis, but others did not show this history. One of the simplest cases was in a traveling man who always suffered while on the road, but who was at once relieved by marital relations upon his return home. The man had once had gonorrhea, but there is no mention of an epididymitis. Another man who never had had gonorrhea, always developed swelling and tenderness of the epididymi, after a single episode of prolonged excitement without gratification. A great variety of similar cases could be cited from authors, but Heller believes that the older teaching is all based on anatomical misunderstanding. From Eberth's "Anatomy of the Male Genitals" he obtains the idea that the testicular adnexa called the "paradidymis" is the true seat of these clinical affections. It is really the remnants of an embryonal structure. In a certain per cent. of men it persists, and in a few autopsies has been found to be the seat of compression by tumors, cysts (hydatids). The true mechanism of acute distention and acute relief is undoubtedly dependent on the alternate filling and emptying of the seminal vesicles. Only an autopsy can settle this question beyond doubt.

**Primary Intrahepatic Gallstone Formation.**—Siber reports a case of this unique affection which he cured by hepatotomy. Thus far he has found in the literature no similar case. The clinical report should therefore be the more interesting feature of the case. Patient a woman of 34, no trouble until two weeks before, when she began to feel vague abdominal pains. Within past few days began to vomit bile. Chills with high fever. When first seen was in collapse, and her extreme emaciation made more prominent a tumor in the hepatic region. Diagnosis, hepatic abscess. Laparotomy, with incidental appendectomy. No stones in gall-bladder or ducts. Liver showed tumor, in which fluctuation could be detected. After small incisions had brought away fluid the author made a number of deep ones which laid bare a cavity of the size of the fist. From this cavity 51 stones were extracted, composed of cholesterincalcium. The patient made a good recovery.

**Soothing Screaming Nurslings by Blowing on Them.**—Salge refers to screaming while being handled and quotes Nussbaum in this connection who checks the screaming in part while a hernia is being reduced. The lay press made a feature of this announcement. He then announces that the blowing upon the faces of children by nursemaids for the purpose of quieting them is an old popular custom, which child-conservation enthusiasts have been trying to abolish because of its insanitary possibilities. Aside from the possible infection with a dangerous disease there is danger in spasmophilic children of causing laryngismus. It is the custom of all nursing stations to forbid the practice. The author adds from his own experience a method by which abdominal palpation is facilitated, when the child's screaming interferes. This is simply a rectal enema of choral, which is well tolerated, even by the youngest nurslings. The resourse soon quiets them and being in a sound slumber mild manipulations are well borne.

**Strictures of the Ureters.**—Baar, an American, gives an extensive article on this subject quoting chiefly from American colleagues. Osler admits that there is no medical treatment for the condition. Surgically the simplest resource is gradual dilation. This method seldom succeeds. Kelly with his great experience has notes of some favorable results. The method is ideal in theory. Pyelotomy with rendering patent the ureter has been very little successful in curing pyelitis because of the frequent fistula formation. Kelly has occasionally cured pyelitis by catheterising the ureter and irrigation of the pelvis. In certain cases of inflammation which threaten to envelop the ureter, it has been possible to cut down and isolate the latter. Another portion of the paper is devoted to ureteral strictures simulating stone. He reports such a case in full.

**Thymus, Ovary, and Blood Pictures.**—Heimann sums up his studies as follows: the thymus gives up to the blood substances which influence the lymphocytes. When the gland is removed we see a picture which is confirmed by use of thymus press juice—the loss of the thymus causes a fall in lymphocytic values, while incorporation of thymus matter causes the latter to rise. The lymphocytes in the blood also affect the ovarian secretion, but ovarial press juice acts antagonistically. This means apparently that the entrance of the latter into the blood depresses the number of lymphocytes in the blood.

### Deutsche medizinische Wochenschrift.

*December* 25, 1913.

**Appearance of Menstruation During the Climacteric.**—Levy has recently witnessed a case of this sort which he pronounces extremely rare. His title "appearance of menstruation" should really be reappearance, etc. The woman was born in 1836, and menstruated when 16. At 22 she married and presented the world with 14 children, all breastfed and all born at full term, and from 18 months to 2 years apart. She had never aborted, and in fact, had had no illnesses whatever. Periods always regular, lasting 6 days. At the age of 57 the menses ceased but without any symptoms of climacteric. At 71 the menses reappeared, and regularly until nearly 76. She is now 78 and hale and hearty.

**Saving of Radiant Energy in the Treatment of Inoperable Cancer.**—Klotz gives a résumé of his subject as follows: First he gave intravenously 5 c.c. of electrocobalt. Then during the next two days beginning immediately after the injection he gives from 400 to 450 X—in three localities—belly, back, and vulvovaginal. After 9 days he injects more cobalt and gives radium treatment to the vagina alone (800-1,000 mgm-hours). Again 9 days more he injects 5 c.c. of electrocobalt (as high as 10 c.c. may be given if the kidney is not affected) and resumes the *x*-ray treatments. The electrocobalt is a colloid of the metal, used for its tumoraffin properties which resemble those of selenium. The sole end of this method appears to be in the direction of economizing costly substances.

**Brophy's Cleft Palate Operation.**—Kaerger gives his experience with this long known operation which goes back to 1861. In the meantime there is a long record of poor work, until it was learned that early operations alone promise favorable results, while in older subjects an obturator could be made to give good service. At present the methods of Brophy and Arbuthnot Lane are much in vogue. Both require that the operation should be done in early childhood, losing no time by delay. Lane endeavors to operate before the irruption of the teeth, suturing the hare lip first and leaving the bony cleft to unite in part by natural growth. Brophy after suturing the hare lip unites the bony cleft by an osteoplastic method. The German surgeons thought the latter correct in theory but attended in practice by incomplete results, but after Brophy himself (1911) had demonstrated his methods, instruments, etc., they regarded it in a new light and the author sought to try it out in Bier's clinic, at the latter's request. Some results are as follows: There were six cases of double hare lip, fissures in upper jaw and palate. Four of these were cured completely, while the other two are now under treatment. There were 25 cases in which the same condition was unilateral; 13 patients have already recovered, the rest presumably under treatment. In 7 other children the fissures were limited to the palate (hard or soft) or palate and lip, the jaw bone being intact. There is allusion to 15 cases of simple cleft palate, 13 of which were cured by Brophy's method, and the other 2 are under treatment.

---

**The Chemotherapy of Tuberculosis.**—L. Rénon reports the results of his experimental and clinical observations on this subject. He investigated three classes of substances: (1) radioactive substances as radium and thorium; (2) mineral salts; and (3) electrical collodidal metals. The bromide and the sulphate of radium had no effect upon cultures of the tubercle bacillus, nor did either of these substances prevent or arrest the development of experimental tuberculosis in the guinea-pig. Variable results followed the use of ether agents on human beings. Whatever benefit had been derived was probably the consequence of psychic influence. The same results were obtained with thorium. The next set of experiments were carried out with the salts of nickel, yttrium, zirconium, and calcium. Chloride of nickel in a concentration of 6 to 1000 prevents the growth of a culture of tubercle bacilli, but it had no effect on the disease in the guinea-pig. In the human being doses of 5 centigrams of nickel chloride diminish expectoration and reduce the temperature in some patients but have no effect on the evolution of the disease. Chloride of yttrium has no effect on cultures of the tubercle bacillus, neither does it arrest tuberculosis in the guinea pig. Doses of 10 centigrams in the human being improve the general condition but have no effect on the pathological process. Chloride of zirconium inhibits slightly the development of the cultures, and the evolution of the disease in guinea-pigs. Doses of 2 centigrams in man improve the general condition, particularly the weight and the appetite, and diminish the expectoration, but otherwise they have no effect. The author has obtained good clinical results with the tannate and albuminate of calcium. Electrical colloidal preparations of nickel, silica, ruthenium, and carbon were found to have no curative influence in tuberculosis. Nickel and ruthenium may relieve the secondary infections.—*Bulletin Général de Thérapeutique.*

# Insurance Medicine.

## SUGGESTIONS TO MEDICAL EXAMINERS.

BY THE INSURANCE EDITOR.

### PLEURISY.

A STUDY of insured lives with a history of pleuritis shows an excessive mortality, the rate varying in a general way according to the form in which the attack declared itself. The cause of this high death rate is readily understood in view of the recognized fact that the tubercle bacillus, alone or in combination with other organisms, is frequently responsible for the attack of pleuritis. A good many medical examiners attach too little importance to a history of pleuritis if one judges by the incomplete reports submitted by them.

*Dry or Fibrinous Pleurisy.*—The proportion of cases in which the presence of the tubercle bacillus is a factor in the etiology of dry pleurisy is large, though not definitely known. Osler obtained a positive tuberculin reaction in 33 per cent. of a group of cases. The same authority further states that out of 60 cases followed up after discharge from the hospital, 30 per cent. developed pulmonary tuberculosis during the next twelve years.

Certain mistakes are liable to occur in the diagnosis. For instance, it is quite probable that a small amount of liquid is present in many of the so-called cases of "dry pleurisy." Other mistakes arise through the confusion of dry pleurisy with pleurodynia, due to the fact that both ailments give rise to the same characteristic pain, and that dry pleurisy is sometimes indicated by this pain alone. Therefore when a history of either ailment is acknowledged an effort should be made to find out the true nature of the attack.

*Serofibrinous Pleurisy.*—It is generally accepted that a large percentage of the cases of pleurisy with effusion, the so-called primary as well as those secondary to tuberculous lesions, are due to the invasion of the tubercle bacillus. The proportion varies from about 25 to 85 per cent., according to different observers. The remaining non-tuberculous infections are usually due to the presence of the pneumococcus or streptococcus, or both. The belief that a large number of the cases of serofibrinous pleuritis are tuberculous is supported by the fact that many of those who recover from the effusion suffer afterward from tuberculous disease. Bowditch followed up ninety cases and found that thirty-two of them died subsequently of pulmonary tuberculosis. Hedges traced 130 cases treated at St. Batholomew's Hospital and found that 40 per cent. of them became tuberculous within the next seven years. Of 300 cases treated in the Massachusetts General Hospital and followed up by Cabot, 117 died within five years. As Osler puts it, the chances are about three or four in ten that an individual with pleurisy with effusion will develop pulmonary or other tuberculosis within a period of six or seven years.

It should not be forgotten that the foregoing estimates are based upon experience with the inmates of large public hospitals, and that it is not fair to compare them with the results which may be expected among the class of people who apply for life insurance. Generally speaking, the latter are more amenable to good advice and more apt to consent to a careful supervision and regulation of their daily life in the years following the pleurisy. Nevertheless the ultimate results in the better class are unfavorable enough to materially increase the hazard of insuring the individuals of the group.

*Purulent Pleurisy.*—Most pathologists consider that empyema is seldom due to the presence of tuberculosis, and that it usually occurs as a pure infection by the pneumococcus or streptococcus or both. The finding of these organisms does not, however, necessarily exclude the tubercle bacillus.

*Conclusions.*—The results obtained by the different authorities are corroborated to a large degree by the experience of life insurance companies.

It will often be difficult to secure a definite history of the original attack of pleurisy, but the medical examiner should make an earnest effort to elicit the important points, especially the precise date, duration, severity, and form; furthermore, whether there was any suspicion of tuberculosis. A close and searching inquiry should be made into the family history and suspicious causes of death should be positively cleared up. It should be made clear, whenever there has been a sudden increase in weight, whether it was due to forced feeding or change in climate and whether the previous lighter weight was due to any illness. A loss of weight is still more important and should be regarded with suspicion. The habits, occupation, and surroundings should receive careful attention, and the examiner should ascertain if the applicant lives in overcrowded quarters and understands the importance of the proper disposal of infected material.

The physical examination should be made with all clothing removed from above the waist, and a careful and painstaking search should be made for old adhesions and thickening of the pleura, especially at the apices. Adhesions often exist as the sequel of simple pleurisy occurring during an attack of pneumonia and unless they are extensive or situated at the apices will usually be ignored by the approving officers at the home office when they are convinced that pneumonia without tuberculosis was the provoking cause.

Even after the examiner has made a searching inquiry and strict examination, there still remains a doubt which can only be cleared up by the physician who attended the patient during the actual attack, and who is the only one in a position to give definite and authentic information as to the character of the pleurisy. For this reason the companies usually require the applicant to furnish a statement from the attending physician in addition to submitting to the regular examination.

The experience of clinicians and of the various companies teaches that it is unwise to insure an individual who has had dry or serous pleurisy until at least five years have elapsed since full recovery, and that even then he should be scanned carefully with regard to other conditions which tend towards tuberculosis. When an applicant has had empyema, a full history of the attack should be reported, even though the information will not be regarded seriously at the home office if a period of about two years has elapsed, the applicant has regained his former weight and health, and there is no marked thickening of the pleura or deformity.

---

**Life Insurance a Guarantee for Marriage.** — French says that a man possessing a life insurance policy furnishes a sufficient guarantee to the woman who is desirous of marrying him, and that it should be one of the demands made by the bride-to-be that the marrying man possess this passport to physical fitness and long life.—*American Medicine*, October, 1913.

# Book Reviews.

Die Ambulante Therapie der Lungentuberkulose und Ihre Haufigsten Komplikationen. Von Dr. Karl Blümel. 208 pages. Price, 6 marks. Berlin: Urban. New York: Rebman Company, 1913.

This monograph is dedicated to the memory of Hermann Brehmer, the creator of present day phthisiotherapy. The author enumerates the indications and contraindications of ambulatory treatment of tuberculous patients. He strongly emphasizes the fact that the febrile patient can not be treated in a dispensary, nor can those whose home hygiene or personal characteristics make the careful carrying out of the hygienic and dietetic directions an evident impossibility. Although not absolutely new, Blümel recommends "Luft und Sonnenbäder" as part of aerotherapy. These therapeutic means are relatively rarely resorted to by our American phthisiotherapeutists, although their value, when carefully carried out, seems unquestionable. Hydrotherapy the author considers of greatest importance in the treatment of pulmonary tuberculosis. He insists that the ambulant patient should receive most careful instructions concerning his mode of life. The rest of the volume is devoted to tuberculin therapy and does not offer anything new; on the other hand, it is interesting to note a short chapter on chemotherapy. He mentions dioradin (a preparation recommended by Bernheim of Paris and which met with little success in this country), but speaks discouragingly of it. The cases in which he tried it ended fatally. In the same chapter Finkler's iodide of methylene blue is mentioned as well worth a trial in selected cases. Under symptomatic treatment the author emphasizes very justly the great importance of the mental quiet of physician and patient in case of a hemoptysis. All in all, the monograph deserves a careful perusal by practitioner and specialist.

The Practical Medicine Series. Comprising Ten Volumes on the Year's Progress in Medicine and Surgery. Under the General Editorial Charge of Gustavus P. Head, M.D., Professor of Laryngology and Rhinology, Chicago Post-Graduate Medical School. Charles L. Mix, A.M., M.D., Professor of Physical Diagnosis in the Northwestern University Medical School. Volume III. The Eye, Ear, Nose and Throat. Edited by Casey A. Wood, C.M., M.D., D.C.L.; Albert H. Andrews, M.D.; Gustavus P. Head, M.D. Series 1913. Price $1.50. Chicago. The Year Book Publishers.

"It is possible that the practice of ophthalmology, like that of dentistry, may come, in America, at least, to form a distinct department of surgery." This quotation from the book sums up the writer's discussion of the optometry question and the necessity for better facilities in our universities for the study of ophthalmology. In an article on the conservation of hearing, J. F. Barnhill says: "Much of the deafness as it exists to-day is entirely unnecessary; it should have been prevented by a closer and more intelligent attention to the ear on the part of the profession, and by a more responsive cooperation on the part of the parents or those having control over children in the first decade of their lives." Some space is devoted to the subject of orthodontia and its relation to rhinology. These are only a few of the many pertinent subjects treated in this book.

Die Untersuchung der Luftwege. Ein Vortrag zur Einführung in die moderne Rhino-laryngologie fur Ärzte und Studierende von Dr. P. H. Gerber, A.O., Professor und Director der Königlichen Universitäts-Poliklinik für Hals- und Nasenkranke zu Königsberg. Mit 49 Text-Abbildungen und 12 Abbildungen auf 4 tafeln. Forty-five pages. Price 2 marks. Würzburg; Verlag von Curt Kabitzsch, 1913.

This is a profusely illustrated small booklet on the most practical and modern examinations of the nose, posterior nares, pharynx, larynx, trachea, and bronchi. The contents are very instructive.

Verhandlungen des Vereins Deutscher Laryngologen, 1913. Herausgegeben im Auftrage des Vereins vom Schriftführer Prof. Dr. Rich. Hoffmann, Dresden. Price 7 marks. Würzburg: Verlag von C. Kabitzsch, 1913.

The book consists of the business and scientific portion of the society. Some of the contributors to the latter are Drs. Killian, Oppkofer, Thost, Brüggemann, Blumenfeld, Preysing, Marx, Ephraim, Spiess, Kahler, Solger, Denker, Albanus, Gutzmann, and about a dozen others. The topics cover a large field in this specialty, such as bronchoscopic tubes for children, diagnosis of carcinoma of the larynx, operations on the hypophysis, theory of bronchial asthma, positive Wassermann's reaction in malignant tumors, electrochemical treatment of laryngeal tuberculosis, paralysis of the recurrent nerve in mitral stenosis, comparative bacteriology of the nose and mouth, intranasal opening of the frontal sinus, etc.

Die Röntgendiagnostic der Darmkrankheiten. Von Dr. M. Faulhaber, Privatdozent an der Universität Würzburg. Mit 34 Abbildunger im Text. Price 1.50 marks. Halle a. S. C. Marhold Verlagsbuchhandlung, 1913. (Sammlung zwangloser Abhandlungen aus dem Gebiet der Verdauungs- und Stoffwechsel-Krankheiten. Prof. Dr. A. Albu in Berlin. V Band, Heft 1.)

This contains a description of the technique of Röntgen diagnosis in intestinal disease, with findings in the normal tract, action of drugs, anomalies of form and position, chronic functional obstipation, ulcerations, stenosis, and adhesions.

Technik der Ärztlichen Massage für praktische Ärzte. Von Dr. Anton Bum, Privatdozent an der Wiener Universität. Mit 54 Textabbildungen. 109 pages. Price, 3.30 marks. Berlin, Wein: Urban & Schwarzenberg. New York: Rebman Co., 1913.

This small unpretentious volume appearing at the same time as the author's much larger work, "Handbuch der Massage und Heil Gymnastik," deals with the physiological indications and method of application of mechanotherapy in different diseases. The book shows in word and picture the technique of medical massage which the author has practised for many years. A consideration of massage in the specialties, like laryngology, rhinology, and otology is omitted, since the book is intended for the general practitioner.

Die allgemein pathologische Bedeutung der Dermatomykosen. Von Bruno Bloch, Basel. Price 3 marks. 110 pages. Halle a. S.: C. Marhold, 1913.

The dermatomycoses falling into the two great groups of favus and trichophytoses are here discussed. Their symptoms, the clinical manifestations of their various subdivisions, and pathological physiology (biology) are taken up. Many cases are discussed in great detail with results of immunization tests, etc. An extensive bibliography is attached.

Über Kinderrekzeme. Von Prof. V. Klingmuller in Kiel. 35 pages. Price 1 mark. Halle a. S.: C. Marhold, Verlagsbuchhandlung, 1913.

A comprehensive discussion of the eczematous diseases of the child in the light of the newer teachings of diatheses, dyscrasias, autointoxications, and anaphylaxis.

Die Störungen der männlichen Geschlechtsfunktionen und ihre Behandlung. Von Dr. Emil Kantorowicz. Price 3 marks. Berlin: Urban and Schwarzenberg. New York: Rebman Company, 1913.

The author takes a conservative view of the therapy of the disorders of the male sexual organs. Some space is devoted to the psychical suffering frequently accompanying such disorders and the methods to alleviate it. In the chapter devoted to genuine psychopathies and perversions, however, Dr. Kantorowicz seems inclined to the attitude of a judge rather than that of a physician, and rejects perhaps too absolutely the ideas of irresponsibility and congenital disposition. This attitude may act in the consulting room as invigoratingly as a cold douche on enervated constitutions.

Sterilisation und Kastration als Hilfsmittel im Kampfe gegen das Verbrechen. Von Dr. Friede Ludw. Gerngross. Preis 1.20 marks. München: J. F. Lehmanns Verlag, 1913.

Dr. Gerngross believes that forced sterilization is only justified from the eugenics standpoint, and that it is indicated in cases of criminals who have shown an inborn criminal instinct which can be traced to heredity (either criminal, insane, epileptic, or alcoholic). Also in cases of idiots, epileptics, and the insane; in cases of drunkards who have been treated several times successfully in asylums, and in cases of the mentally deficient below a certain standard. From the legal point of view, Dr. Gerngross concludes that society has an undoubted right to protect itself by any measure it deems proper, and that sterilization has no such ill effects even physically on the criminal as imprisonment for years.

Diagnostic Methods, Chemical, Bacteriological and Microscopical. A Textbook for Students and Practitioners. By Ralph W. Webster, M.D., Ph.D., Assistant Professor of Pharmacological Therapeutics and Instructor in Medicine in Rush Medical College, University of Chicago; Director of Chicago Clinical Laboratory. Third edition, revised and enlarged. With 37 colored plates and 64 other illustrations. Price $4.50 net. Philadelphia: P. Blakiston's Son & Co., 1913.

The rapidity with which this work has reached a third edition is sufficient evidence that its worth has been appreciated by the medical profession. In its revised form the book presents in a remarkably full and exhaustive manner the diagnostic methods in use in all parts of the civilized world. Only those tests, however, have been included which have undergone the fire of criticism or which have opened up somewhat new fields of investigation. Among the changes and inclusions in this edition may be mentioned a discussion of streptococcic sore throat; Darling's method of staining amebæ; Rose's method for creatin; Hart's qualitative test for β-oxybutyric acid; Pappenheim's panoptic blood stain, and Collignon and Rilod's test for meningococcic meningitis. Also pregnancy has been given in great detail. It is becoming more and more evident that chemical, bacteriological, and microscopical tests are absolutely essential, in the majority of diseases, to a correct diagnosis and that therefore laboratory work is the necessary corollary of clinical examination. The book is well arranged, well printed and provided with a sufficiency of illustrations and diagrams. Dr. Webster may congratulate himself on having written a work which in its revised form cannot but prove extremely useful to the up-to-date medical practitioner.

Taschenbuch der Magen- und Darmkrankheiten. By Dr. Walter Wolff, Oberarzt der inneren Abteilung am Augusta Hospital, Berlin. Mit 13 Textabbildungen und 1 farbigen Tafel. Price, 4 marks. Berlin and Vienna: Urban & Schwarzenberg; New York: Rebman Company, 1912.

An unusually comprehensive and complete description of the diseases of the stomach and intestinal tract is presented in this manual of 164 pages, which is based upon the methods of diagnosis and treatment of gastro-intestinal disorders as carried out in the Augusta Hospital of Berlin under the direction of Professor Ewald. The author emphasizes the point that the technical difficulties of examination and treatment are overemphasized by the general practitioner. The various methods employed in gastroenterology are briefly but fully described. Special stress is laid upon the differentiation between organic and functional conditions. The subject of treatment is accorded more ample space than is usually given in the smaller textbooks.

Indigestion, Constipation, and Liver Disorder. By G. Sherman Bigg, Fellow of the Royal College of Surgeons, Edinburgh; Member of the Royal College of Surgeons, England; Licentiate of the Society of Apothecaries, London; Fellow of the Royal Institute of Public Health; Honorary Surgeon of the Society for Prevention of Cruelty to Animals; late Surgeon-Captain, Army Medical Staff; Staff Surgeon. Allahabad, Indies; Surgeon Medical Charge of Officers, Women, and Children, Brighton and Dover; Sanitary Medical Officer, Shorncliffe Camp; Surgeon-in-Charge, Native Followers' Hospital, Allahabad, India; Surgeon-inCharge, Women's Hospital, Allahabad, India. Price, $1.50. New York: Paul B. Hoeber, 1913.

This small manual presents an interesting and practical discussion of constipation, indigestion, and liver disorders, which are probably the most common ailments that the physician is called upon to treat. The detailed management of these conditions is given and useful prescriptions are included in the text.

Diagnose und Therapie der Herzkrankheiten. By Von Prof. Dr. Ludwig Braun, Primararzt in Wien. Zweite, vollständig umgearbeitete Auflange. Mit 37 Text figuren. Price, 15 marks. Berlin and Vienna: Urban & Schwarzenberg; New York: Rebman Company, 1913.

Since the publication of the first edition of this work in 1903 the study of heart disease has been greatly enhanced by the use of radiography, by the discovery of the conducting system, by the recognition of the full significance of the venous pulse, and by the application of electrocardiography in the study of the abnormal events in the heart cycle. All of these developments are described and given their due application in the second edition of this work, which, like the first edition, is designed as a textbook for the student and practitioner. The various topics are taken up in the following order: physiological conceptions; the pathological changes in the heart; general diagnosis; the signs of cardiac impairment, and general therapy, including a full discussion of the action and indications of the numerous drugs used in cardiac therapeutics, dietetic measures, and physical agents, the carbonic acid bath, etc. There is a special chapter on the hydratic treatment of cardiac disease by Alois Strasser, and one on the mechanical treatment of heart disease by Anton Bum. The next portion of the book is headed Special Section and discusses separately the chronic cardiac insufficiency, the diagnostic and therapeutic aspects of arteriosclerosis, the diagnosis of syphilis of the circulatory apparatus, acute cardiac insufficiency, the principles in the prophylaxis and treatment of chronic cardiac insufficiency, aortic aneurysm, and the heart neuroses. The book is exceptionally complete and well written. Ample attention is paid to the subject of treatment and many useful prescriptions are incorporated in the text.

Theorie und Praxis der Inneren Medizin. Ein Lehrbuch für Studierende und Ärzte von Dr. Erich Kindborg in Bonn. Dritter Band: Die Krankheiten der Nieren und der Harnwege. Die Blutkrankheiten. Die Erkrankungen des Nervensystems. Die allgemeinen Infektionskrankheiten. Die Wichtigsten Vergiftungen. Mit 71 Abbildungen im Text und auf 4 Tafeln. Price, 13 marks. Berlin: Verlag von S. Karger, 1914.

This is the third and concluding volume of a work which the reviewer has already characterized as an original presentation of the subject of internal medicine. It is a combined textbook on medicine, clinical pathology, medical physics and chemistry, pharmacology, and therapeutics. The advantages to the student of coordinating the various studies whose ultimate aim is the single one of relieving human suffering, are obvious. Thus, before discussing the clinical manifestations of any group of diseases the author describes the physical and chemical methods employed in their diagnosis. In the sections on treatment the author shows the graphic formulæ and the relationship of the drugs that are commonly used. Three interesting and valuable tables are those that contrast the numerous modern hematinics, diuretics, and narcotics. The present volume deals with the diseases of the kidneys and urinary passages; the blood and its diseases, the diseases of the nervous system; the general infections diseases, and the most important forms of poisoning. As mentioned in the reviews of the previous volumes considerable attention is paid to the subject of treatment. From the didactic viewpoint this work is planned on correct psychological principles. It is eminently practical and will undoubtedly enjoy a wide circulation among German students and others who are able to read the German language.

Die Krankheiten der Nase und Mundhöhle sowie des Rachens und des Kehlkopfes. Ein Lehrbuch für Ärzte und Studierende. Von Dr. Alfred Bruck. Berlin. Zweite, wesentlich vermehrte und verbesserte Auflage. Mit 252, zum Teil farbigen Abbildungen und 2 Tafeln. Price, 14 marks. Berlin and Vienna: Urban & Schwarzenberg; New York: Rebman Company, 1912.

This is the second edition of Bruck's well-known textbook on the diseases of the nose, mouth, and throat. It represents a revision and enlargement of the former edition, such new topics being included as radiography in nose and throat work, the suction of the alæ nasi inwards against the septum, Killian's frontal sinus operation, emphysema of the parotid, etc. The last-mentioned condition is described as occurring in glassblowers, and the result of the dilatation of Steno's duct and the entrance of air into the alveoli of the parotid. Many parts of this work have been rewritten, as those dealing with the diseases of the accessory sinuses, the direct methods of examination, tuberculosis of the larynx, and disorders of the voice. This book may be recommended to the student and practitioner. It is unusually complete and succinct, and is eminently practical.

# Society Reports.

## SOUTHERN SURGICAL AND GYNECOLOGICAL ASSOCIATION.

*Twenty-sixth Annual Session, Held at Atlanta, Georgia, December 16, 17 and 18, 1913.*

THE PRESIDENT, DR. JOHN YOUNG BROWN, ST. LOUIS, MISSOURI, IN THE CHAIR.

**Successful Suture of Stab Wound in Right Ventricle of the Heart.**—Dr. JOSEPH DANNA of New Orleans summarized the salient points in connection with the case as follows: (1) The whole procedure was very easy and could have been done by any one possessing the average surgical ability. (2) The removal of the third, fourth, and fifth costal cartilages and free incision of the pericardium, exposed the heart to the full view of all the bystanders. (3) Manipulation of the heart was not attended with either shock or pain; the patient talked and felt comfortable during the process of suturing, sponging, etc. (4) The heart moved very freely, but could be steadied by forceps or sutures without harm. (5) The placing of the sutures through and through did no harm in this case, although that was also advised. (6) The pleura was opened in getting the proper exposure, an accident which usually happened in those cases, but which he believed might have been avoided with care. (7) The heart alternately contracted and relaxed, and during the state of relaxation it felt as soft as jelly. (8) Every case of wound of the chest, with signs of severe hemorrhage, where the bleeding was believed to be the result of injury to the intercostals, internal mammary, or the heart or its coverings, should be operated upon. No case should be considered too far gone for operation. If that was done, a life would occasionally be saved, and more reports of suture of heart wounds would find their way into medical literature.

**Direct Suture of the Brachial Artery for Traumatism; Restoration of Circulation; Subsequent Development of Ischemic Paralysis.**—Dr. J. GARLAND SHERRILL of Louisville, Ky., reported the following case: The patient, a young man twenty-three years of age, was first seen about an hour after an injury which had resulted from torsion of the arm and had produced a dislocation at the elbow, with rupture of the brachial artery. He was complaining greatly of pain; there was marked swelling in the forearm, which was purple in color, and also an entire absence of radial pulsation, but there were no symptoms of false aneurysm present. Both bones of the forearm were dislocated backward at the elbow, but the skin of the arm was unbroken. It was at once suspected that the brachial artery had been severed; his arm was at first immersed in hot water for some time to determine whether or not the circulation could be restored. At the end of three hours, there being no improvement and a marked increase in the pain, swelling, and discoloration, an incision was made down to the brachial at the bend of the elbow. The humerus, which was lying in front of the condyle of the olecranon, was restored to its position; the ends of the brachial artery stood forth prominently in the wound, both being filled with blood clot, no fresh blood being present. A small amount of clot was found among the torn muscles. It seemed to the writer that with the blood vessel occluded a noticeable collateral circulation should have formed by this time, if such result were likely to obtain. Therefore, it was concluded that a direct suture of the torn ends of the artery offered to the patient the best possible chance of saving his arm. The clots were removed from both the distal and proximal ends of the vessel and a Crile clamp then placed upon each to control the bleeding during the steps of the operation. It is likely that the clamp on the lower end was not necessary, as that vessel did not bleed when the clot was removed, but its use facilitated considerably the manipulation of the torn vessel. The sheath of the artery was torn away from the distal portion and had contracted somewhat over the proximal end. This was held out of the way while the vessel itself was sutured. In making the anastomosis, the method described by Carrel and employed by Crile was used. A very fine linen thread was separated into its three primary strands, one of which was carried through a very fine round needle (No. 16, Kirby), the thread being previously saturated with sterile vaseline. Three guy sutures were passed through the coats of the vessel; the lower suture was held by a forceps which was allowed to hang down, and the other two caught by forceps which were held by my assistant, thus giving a straight line for the suturing, which was done by continuous suture. The dragging of the forceps below prevented any possibility of catching the wall opposite the line of intended suture. The vessel was turned after each suture in such a way that each side of the triangle was completely closed. After the anastomosis was accomplished the clamps were released and the blood was allowed to flow, a small amount escaping; an additional suture controlled the hemorrhage and the sheath was drawn down from the proximal side and united to that from which it had been torn below. Following this the clamps were again removed and the blood allowed to flow through the line of anastomosis, which it did without any escaping from the vessel. The median nerve was exposed in the wound, but was apparently uninjured. The wound was closed without drainage, and the arm put up in a voluminous dressing in a position of partial flexion. Within five minutes after the suturing of the vessel was completed the circulation had returned in the hand, although we were unable to certainly determine a pulse at the radial artery. Some time elapsed before a distinct pulse could be felt at the wrist. However, it was soon restored, and is still easily felt. The patient made a somewhat protracted convalescence and was disturbed some by the numbness in the fingers, which was thought to have resulted from the stretching of the median nerve.

**Surgical Repair of Blood Vessels: Its Technique, Its Uses and Limitations.**—Dr. J. SHELTON HORSLEY, of Richmond, Virginia, said that sensational newspaper articles had done blood-vessel surgery much harm. Even in animals no organs such as the kidneys and no limbs had been transplanted with permanent success. A transplanted limb continued paralyzed and useless, and while a transplanted kidney might functionate for a while, it gradually lost its structure. However, blood-vessel surgery had four fruitful fields: (1) Trauma of the vessels. (2) Malignant growths that involve the blood-vessels. (3) Aneurysms. (4) Transfusion of blood. In suturing vessels, Dr. Horsley claimed the same principle of approximating endothelium obtained as in suturing intestines—only the endothelium was on the *inside* of the vessel, while on the *outside* of the bowel. So in suturing vessels a flange must be turned *out*, just as in suturing intestines it must be turned *in*. He described his technique for vessel suturing. Three guy sutures were inserted and attached to buttons on an arterial suture staff of his design. The threaded ends of the last two guy sutures were not cut, but used as a double mattress, or cobbler's stitch. The suture staff converted the circumference of the vessel into a triangle and the vessel was held so that the intima was everted in the third that was being sutured. All stitches were placed under the same tension instead of under varying tension as when the sutures were held by hand, and a flange with everted intima was turned out, the intima being accurately approximated by the cobbler's stitch.

Dr. R. H. HILL, of Montgomery, Ala., stated that his interest in this subject began when he saw a case in the service of his brother, Dr. L. L. Hill, of a needle stuck in the heart of a little girl. The needle was removed under local anesthesia. The external end of the needle could be seen plainly under the skin with each movement of the aorta. In another case he assisted his brother in removing a piece of a hat pin from the heart of a negro man. The man suffered no special inconvenience, although his pulse was irregular as long as he occupied the upright position, but when he undertook to lie down he had considerable pain and great difficulty in breathing. The foreign body was removed by a modified Rotter operation. He also assisted his brother in suturing the heart of a boy who was stabbed with a penknife.

Dr. WALTER C. G. KIRCHNER of St. Louis had seen five cases of heart suture and had operated on two himself. One of the patients on whom he operated recovered. It was important for the surgeon, who was likely to have emergency work of this kind, to have a definite plan of operation, a definite means of opening the chest, so that it could be opened quickly and without much confusion. Deep anesthesia was dangerous because when the chest was opened the function of the lungs did not work as well as when the patient was partially anesthetized. So it was better to use light general anesthesia or local anesthesia. The danger of pneumothorax had been overestimated. In all the cases where

he had seen the chest laid wide open, the lung functionated to a moderate extent when the chest was widely opened, so that repair of the heart even under these conditions could be undertaken.

Dr. HERMAN J. BOLDT of New York City suggested that rectal anesthesia might well be substituted for general anesthesia in these cases.

Dr. FRANCIS REDER of St. Louis said it might be a refinement in technique, but the suture he had employed was that instead of placing the matress suture parallel with the plane of the intestine, he had placed this suture vertical to the axis of the vessel.

Dr. I. S. STONE of Washington, D. C., asked Dr. Sherrill how much usefulness of the arm was preserved in the case he reported.

Dr. SHERRILL, in reply, stated that he had considerable power in carrying things on the forearm; that he had some prehensile ability and could pick up things with the fingers to a small degree, but the result was not as satisfactory as he had hoped to obtain.

**Accidental Injury to the Vena Cava During Nephrectomy.**—Dr. LEGRAND GUERRY of Columbia, S. C., reviewed the literature and reported three cases in which he had injured the vena cava during an operation for the removal of the kidney. In the first two cases it was his belief the accident was unavoidable. In the last case, in spite of care used, his feeling was it should not have occurred. In one case the hemorrhage from the torn vena cava was successfully controlled by gauze tamponade. In all his cases the clamp alone was used to close the injured vessel wall. The clamp was unlocked on the seventh day and removed on the eighth day.

**Elements Frequently Overlooked by Surgeons in the Treatment of Exophthalmic Goiter.**— Dr. A. J. OCHSNER of Chicago discussed the following ten features whose consideration had a distinct bearing upon the surgical treatment of exophthalmic goiter. (1) The physiological hyperthyroidism present during pregnancy, puberty, etc. (2) That resulting when persons suffering from goiter and living in goiter districts changed their residence to other regions. (3) A class of patients was considered who maintained a balance between production and consumption of thyroid secretion until this balance was disturbed by some sudden physical, mental, or emotional strain. (4) The necessity of planning the operation in relation to the margin of safety in the individual cases as pointed out. (5) The importance of bearing in mind the periodicity of exacerbation in hyperthyroidism and its relation to proper time of operation was considered. (6) Attention was once more directed to the harmfulness of undue operative traumatism. (7) The relation between absorption of wound secretion and post operative hyperthyroidism was discussed. (8) The uselessness and harmfulness of heart stimulants, thyroid extract, and iodine were mentioned. (9) The question of anesthetic was given due consideration. (10) And last and most important of all definite rules for after treatment were laid down with a view to prevent the patient from falling back into the unhygienic modes of life without which she would probably never have suffered from exophthalmic goiter.

**Choice of Operations for Retroversion When the Abdominal Cavity Is Opened.**—Dr. HENRY T. BYFORD of Chicago stated that Alexander's operation utilized the round ligaments in a natural way by drawing toward the inguinal ring, so the intraperitoneal shortening should draw in the same direction. It should also preserve the normal uterine attachment and best part of the ligament. It should not change the relation of the uterus to its surroundings. The relief should be permanent and not nullified by postoperative complications. There were certain objectionable features that should be avoided, namely, dependence upon peritoneal adhesions, for they were unreliable; the production of exudates, for they interfered with normal mobility and were apt to produce symptoms; the leaving of exposed sutures in the peritoneal cavity, for they gave rise to exudates and adhesions; the suturing of the uterine body in any way, for it frequently interfered with normal function traction in an upward direction, for it should, as far as possible, be downward upon the filling and emptying bladder. The steps of the operation were as follows:—the ligament was grasped near its exit from the internal inguinal ring and pulled toward the median line until it was taut. A slender 20-day catgut thread was passed through it about a centimeter from the internal inguinal ring and again about five centimeters from its uterine attachment, and tied. The edges of the resulting loop of the ligament were sewed so that it would form a double cord, and leave the end of the thread projecting beyond its free end. Then separate the peritoneum freely from the abdominal wall at the lower end of the incision laterally as far as the internal inguinal ring. With the point of a pair of slightly curved hemostatic forceps puncture the peritoneum from without inward about a centimeter mesially from the ring, grasp the thread and pull the loop through the puncture until all of the sutures are extraperitoneal. With a permanent suture the loop is attached at a point about a centimeter from its base to the inner surface of the abdominal wall as near the inner ring and as low down as possible without risk of puncturing the epigastric or femoral artery. The pulsating arteries are easily felt, and each step of the operation should be guided both by sight and touch. Twist the loop half way around on its long axis and sew it with catgut along the abdominal wall toward the median line. The same is done on the opposite side with the other ligament and the abdomen closed. A small pessary should be introduced to be worn for about three months. When the operation is done in this way the sutures are all extraperitoneal, the intraperitoneal relation of parts is practically normal, and the traction of the ligament is toward the internal inguinal ring.

**Artificial Vagina by Intestinal Transplantation.**—Dr. H. J. BOLDT of New York reported two cases of formation of an artificial vagina by intestinal transplantation, and said that it was the only method that had given a satisfactory result. Other methods that he had used were eventually always failures. In both of his cases there was a complete congenital absence of the vagina. His first step was to open the abdomen and to eliminate a sufficient length of ileum to make the artificial vagina —about twelve inches—and then to reestablish the intestinal tract by lateral anastomosis. He believed that this was freer of risk to injury of the rectum and bladder than to first make the canal into which the artificial vagina was to be implanted. The making of this canal was easily done without appreciable risk of injury with the abdomen open. The eliminated part of the ileum was grasped with a spongeholder at its median part and drawn down to the vulva and there sutured all around the vulva. The apices of the bowel used to make the vagina were then fastened in the pelvis and the abdomen was closed, after covering the vault with pelvic peritoneum. The bowel was then opened and its interior wiped out with a gauze strip saturated in boric acid solution, but this was not, in his opinion, absolutely necessary nor essential, since all the mucus and contents would drain out during the days after operation. After the bowel loop had been opened, the everted mucosa was further fastened to the vulva with silk sutures. In the main his technique was that devised by Baldwin. In both of his cases the result was all that could be desired. Both cases had previously been operated upon elsewhere, but both were complete failures. In his first case the operation was complicated by many intestinal adhesions, due, in all probability, to a previous abdominal operation.

**Adenomyoma of the Rectovaginal Septum.**—Dr. THOMAS S. CULLEN of Baltimore briefly referred to adenomyoma of the uterus, of the round ligament, and of the umbilicus and then considered a hitherto relatively unrecognized growth situated in the rectovaginal septum between the cervix and rectum. The growths had the same histological picture as adenomyomata of the uterus, namely, they consisted of typical uterine glands lying in their characteristic stroma and surrounded by diffuse myomatous tissue. They evidently started in the lower part of the uterus and then spread out in the rectovaginal septum. It was a well-known fact that adenomyomata had an inherent tendency to grow fast to surrounding structures. Thus those growths, which in the beginning might be readily shelled out, later became so fixed to the rectus that it was necessary to take away a portion of the bowel with the tumor. He also stated that these growths could clinically be easily differentiated from cancer of the rectum. Adenomyomata of the rectovaginal septum invaded the bowel from without. They extended into and narrowed the bowel lumen, but the overlying mucosa was still intact. The only rectal symptoms that one might expect were those due to partial obstruction of the bowels. Cancer of the bowel, on the other hand, started in the mucosa and extended outward. It was usually accompanied by hemorrhage from the bowel and later by the fetid discharge, due to breaking down of the cancerous tissue. With adenomyoma of the rectovaginal septum there

was usually no bleeding. On rectoscopic examination in the one case, the cancerous area could be readily seen; in the other, while the bowel was narrowed, the mucosa was nevertheless everywhere intact. While those growths were histologically benign, and while they naturally never gave rise to metastasis, nevertheless, if portions of the growths were left behind they continued to grow and as a result of the adhesions, alarming and, in fact, fatal obstructive symptoms might develop. He also referred to a most interesting case reported by Cuthbert Lockyer before the Royal Society of London, January, 1913. He also mentioned two specimens that were sent him by Dr. D. S. D. Jessup of New York, and reported two cases of his own. He said that the observation of several cases of this character in such a short time seemed to indicate that adenomyoma of the rectovaginal septum was not rare, and that a more careful and systematic examination of all rectal growths would, in the future, bring to light more similar cases.

**Further Notes on the Use of the Paquelin Cautery in Cervicitis; with Special Reference to Its Value in Sterility.**—Dr. GUY L. HUNNER of Baltimore referred to his paper read before the society in 1905 on "The Treatment of Leucorrhea with the Actual Cautery," in which he held that most cases of chronic leucorrhea were due to a cervicitis, and as such were amenable to successful treatment by destruction of the deep cervical glands with the Paquelin cautery. He now reported a series of 241 cases treated with the cautery with practically universal success in the class of cases then outlined as suitable for this method. Now, as in the former paper, he warned against the use of the cautery in the acute or subacute stages of gonorrhea. He also warned against losing valuable time by using the cautery on an early case of epithelioma of the cervix. Any suspicious case that could not be diagnosed grossly should have a specimen removed for microscopic examination. In the chronic inflammatory cases in which a portion of the leucorrhea comes from a metritis or edometritis, the cervical treatments should cease when the cervix had a normal appearance and the cautery failed to empty more retention glands, although there would still persist some leucorrhea from within the uterus. Other pathological conditions for which the cautery had been found useful as an instrument for office treatments were urethral caruncle, polypus of the cervix, fibroma of the vaginal wall, retention cysts and abscesses of Skene's and Bartholin's glands. More recently the writer had found the high frequency spark the ideal method for cauterizing urethral caruncle. This report was made with the special purpose of placing before the profession a method that might prove of great value in handling certain sterility cases. Fourteen cases were reported in which the patients became pregnant after the use of the cautery. Some of these cases had not been married long enough to be classed as sterile, and others had borne children and were probably only temporarily sterile, and others had reposition of the pelvic organs with placement of a pessary, treatments that might have resulted in pregnancy without the use of the cautery. Of the list of fourteen it was more than probable that in six the pregnancy followed as a consequence of using the cautery. Eight cases were reported as failures. Many others complained of sterility and were treated with the cautery, but were not reported; some because of having had only one treatment, others because the presence of a small fibroid or of pelvic inflammatory disease made it probable that the cautery treatment would not give results, and others because the husband's semen had not been examined. Azoöspermia was the cause of sterile marriages in such a high percentage of cases that no method of treating the wife could have its merits passed upon without first excluding the sterilities due to the husband.

**The Treatment of Vesical Fistulæ at the Vaginal Vault Following Surgical Operations.**—Dr. HOWARD A. KELLY of Baltimore stated that occasionally after an operation for a fibroid tumor, and more frequently after an operation for an advanced cancer of the cervix, where the disease had extended anteriorly, a vesical fistula was left which was troublesome and persistent, rarely tending to close of itself. The opening was always found high up at the vaginal vault where it was fixed by scar tissue often inaccessible and difficult to manipulate by any operation through the vaginal introitus. Dr. Kelly had seen such cases operated upon repeatedly and in vain. One of the difficulties arose from the fact that the patient, if she had had a fibroid tumor, was often unmarried or nulliparous, and had a tight vaginal orifice which added to the embarrassment of the surgeon. Furthermore, the margins of the fistula were often thin and devitalized and ill-adapted to denudation and approximation. Added to these technical hindrances was the constant dread of the operator lest he should make a small opening on the peritoneum and introduce infection and run the risk of a fatal peritonitis. Dr. Kelly discovered an excellent plan of operating upon these cases which obviated all the difficulties and dangers, simplified the treatment, and gave a maximum certainty of cure. The patient would lie well anesthetized in the lithotomy posture with the posterior vaginal wall well retracted, if necessary a paravaginal incision was made to expose the vault and the fistula. Then the operator cut transversely just above or through the scar tissue and carefully but with deliberate purpose opened the peritoneal cavity the very first thing. As soon as the peritoneum was opened the incision was continued from side to side until it reached a maximum width and it was possible to introduce three fingers by which it was further extended from side to side until it was as big as it was in the operation for vaginal hysterectomy. This must be done without injuring the bladder or affecting the fistulous tract in any way. The previously taut tissues were now set free to such an extent that they lay loose and flaccid, dropping down towards the outlet into any desired position for denudation and suturing. A good plan now was to incise the tissues longitudinally through the fistula down to the bladder which was dissected away from the vagina and sewed up separately with one or two layers of a fine chromic catgut suture after which the vagina was conveniently united over the vesical wound, if the operator preferred it at a right angle to it so that the two lines of suturing crossed each other. Following such an operation he usually left an opening in the peritoneal cavity about a quarter of an inch wide for drainage. He had in some cases left a considerable part of the vesical peritoneum in the vagina forming a new vaginal vault. A mushroom catheter was put into the bladder for a few days to keep it at rest during the first part of the healing process, and the patient remained in bed from eight to twelve days, the peritoneal drain being removed in from four to six days. In one of his recent cases he started in intending to open through the vaginal vault into the peritoneum, but as he cut a little behind the scar at the vault, he found that he could dissect up the scar area from side to side and detach it and the peritoneum above from the rectum with its fat and so set the tissues free and loosen them up sufficiently from the surrounding parts to be able to bring the fistula down and close it perfectly without opening the peritoneal cavity at all. This was an exceptional case, and the method when applicable was of course better than the last. He felt sure that this procedure of setting free the fistula with all the surrounding tissues in order to denude and suture with perfect accuracy would simplify a class of cases in which they had often found themselves in considerable difficulty in the past.

**The Terminal Results of Biliary Obstruction.**—Dr. HENRY O. MARCY of Boston said that the object of his paper was to show especially that the terminal results of operations upon the biliary passages were serious, at the best often imperfect, owing to the pathological changes which had taken place in the structures. One verdict only could be rendered—that in favor of early operations. It had been truly said, "The easier the diagnosis, the worse the prognosis." Every surgeon was constantly seeing cases of biliary obstruction, diagnosed by the general practitioner too late to give satisfactory results. It was the duty of the surgeon to instruct the general practitioner as far as possible. Just here lay the great profit accruing to the experienced surgeon who had studied a long series of his own operations. Such conditions demanded long and painstaking study. More and more were we individualizing such study, considering the patient's physical state, his resisting powers—all the factors, indeed, which went to make him a warrantable subject for operation. It was probably beyond the limits of human skill always to diagnose the presence of gallstones, it was not to the discredit of a surgeon if, upon operation, they were not found. Exploratory laparotomy was, in itself, not especially dangerous. His clinical records showed that he had opened the abdomen over seventy times when conditions did not warrant further interference. More commonly these were cases of advanced cancer. That experience had been duplicated since the date of examination of his records, without a single fatal result—not too large a percentage in about five thousand abdominal opera-

tions. His purpose was not to dwell upon operative technique. He would urge the utmost care not to overlook a gallstone so placed as to be difficult of detection. This very stone might be the primary cause of obstruction; without its removal, the operation went for naught, and the patient was left worse because of it. Few conditions tested the skill of the surgeon more severely. The trained touch, the *tactus eruditus* of the earlier writers, was nowhere else called into finer requisition. More careful study of the surgical diseases of the abdominal cavity in their earlier stages, especially those of a progressive type, would be sure to lessen mistakes and to broaden the role of surgical intervention. Surgery would no longer be considered as the *dernier resort* by both patient and physician, but would be welcomed as offering a bright promise of speedy and permanent cure.

**Resection of the Rectum for Cancer with Preservation of the Sphincter.**— Dr. CHARLES H. MAYO of Rochester, Minn., said that extirpation of the cecum and ascending colon for cancer had given a high percentage of cures because an anastomosis of the ileum into the colon was an ideal enterostomy for delivering semiliquids. The two-stage Mikulicz method was one of the safest known, although convalescence was protracted. A permanent colostomy, though abhorrent to all patients, undoubtedly gave a higher percentage of cures than did methods which restored function. Mayo advised a colostomy when necessary made through an incision large enough to permit general examination of the abdomen. In a summary of his paper he advised (1) thorough abdominal exploration, (2) a temporary or permanent colostomy in the majority of cases of the type under discussion, (3) increasing the lumen of the anterior and, if necessary, the posterior portion of the bowel to double their normal diameter at the point of union, (4) rotation of the anterior peritoneal-covered bowel to secure rapid healing posteriorly, and practically free peritoneal surface anteriorly, (5) stretching or division of the sphincter to secure drainage of the bowel, (6) closure of the colostomy to secure function, and (7) if there were no metastasis and the colostomy was to be permanent, that the rectum be removed at a second operation.

(*To be continued.*)

## THE PRACTITIONERS' SOCIETY OF NEW YORK.

*Two Hundred and Fifty-seventh Regular Meeting, Held November 7, 1913.*

THE PRESIDENT, DR. JAMES, IN THE CHAIR.

**Occupational Diseases.**—Dr. W. GILMAN THOMPSON read this paper, which was illustrated with fifty lantern slides. (See page 185.)

Dr. MILLER said that he had been greatly interested in this instructive paper. Some of the pictures he had never seen before, and a great many aspects of the subject were new to him, although he had been connected with the work in a minor capacity. It was not too much to say that Dr. Thompson had done more than any other of the profession in this country to stimulate interest in, and to start organized effort to prevent occupational hazards. If the medical profession at large were to cooperate along the lines he suggested it would be a great advance in practical preventive medicine. One question Dr. Miller wished to ask because it had a bearing upon some work he did some years ago in studying the connection between certain dusty trades and pulmonary tuberculosis. In factories such as button, brass and smoking pipe factories, where the dust was intense and often very little protection was afforded to the workers, in some instances he had made as many as 100 physical examinations, and though many workers were affected with bronchial and catarrhal troubles pulmonary tuberculosis did not seem to be very prevalent, nor did the reports upon the health of the other workers point to the prevalence of tuberculosis. In a more extensive study among printers there was shown a high mortality from tuberculosis. Fifteen per cent. of printers in 300 examined were affected with tuberculosis. More than half of these, however, had had tuberculosis previously, had gone away and had come back to take up the same work, but under new home environment, and had kept well. In many cases it was a case of alcohol or bad home environment. Another occupation investigated by Dr. Miller with Dr. Soper was that of subway employees. He had examined about 400 of the men. So much iron dust in the subway was caused by friction of iron that it was estimated to amount to a ton a mile a year. To demonstrate the effect of iron dust the employees were examined. There was a difference between trainmen and motormen. Motormen became fat and were robust, so much so that the expression "subway fat" was applied to them. Trainmen were mostly thin, unhealthy men and many of them had tuberculosis. Perhaps the fact that the motormen had moving currents of air about them all the time made the difference. The environment of the trainmen was stuffy and the air bad. The general impression derived from these observations was that other factors in environment and habits of life were the important ones in the incidence of pulmonary tuberculosis rather than the constant inhalation of various kinds of irritating dust. Could Dr. Thompson throw any light on that subject from his experience?

Dr. MEARA said that the fact that conductors were crowded in with tuberculous people, who coughed in their faces, had much to do with accounting for the large incidence of tuberculosis in the case of conductors.

Dr. STARR said he was much interested in the whole subject and very much indebted to Dr. Thompson. The object of stimulating interest in legislation was a very excellent one, for much work must be done in framing laws for the protection of labor. The matter should be brought before the public by physicians and what they heard should incite them to use their influence in furthering work along these lines. He had gone pretty carefully into the subject two years ago. He was quite surprised to find that all the literature came from England. It had been carefully analyzed by Sir Thomas Oliver and his book, Diseases of Occupation, was one of the important guide books on the subject. He had been much impressed with the fact that in his clinic he saw less of lead palsy than fifteen years ago. Whether this was due to knowledge of preventive conditions on the part of the workers or not he could not say. In the investigations of the Germans on lead poisoning it was found that the typesetters who handled metallic type were poisoned by antimony as much as by lead, which is introduced into the system. Some of the worst cases were due to the mixture of poisons, lead and antimony. In connection with mercurial poisoning a doctor at South Orange sent him every year cases of poisoning from the felt hat factories. He had shown them to the students every year. Two years ago there was a very marked case with tremor of the jaw and very marked mental symptoms, so much so that the patient had to be brought by relatives to the clinic.

Another thing that physicians, who were in touch with the better classes of the community, could do was to try and stimulate the interest of employers of labor to run their factories in a more protected manner. He had succeeded in interesting the president of a large porcelain factory in the question of lead glaze and the results had been satisfactory in that case. In another factory where tooth powder was manufactured the architect had placed ventilators at the top of the room. An intelligent workman remarked to the firm that it would have been better not to have placed the ventilators where the powder would be drawn up past their mouths, but to have put them low down where the powder would have been drawn off. The firm spent $40,000 in correction of the mistake in ventilation, because they appreciated the fact that the workman had made a just criticism. In the case of intelligent employers much could be done in this way.

Dr. DANA said he had been much interested in Dr. Thompson's paper. He had taken great interest two years ago in occupational neuroses. He set his assistants to work to investigate and classify nervous troubles related to occupation. The results had been of direct benefit. In the matter of environment having a direct bearing on the condition of the patients the domestic condition was important. It was not possible to cure one without the other. His assistants had collected 400 cases of nervous trouble to be analyzed on the basis of home and industrial conditions. Specific work had to be done to discover the etiological factor.

Dr. EWING said he was much interested in the presentation of the subject by Dr. Thompson. The question of pathology and etiology was important in dealing with the factors that made up environment. The term occupational diseases could be interpreted in a broader way and everything in the way of pathological processes would be included. The relation of occupation to lobar pneumonia was well known; drivers much exposed to

the cold northwest wind were under the classification of occupational disease. Tuberculosis was always a question of occupation or environment or had some such predisposing cause. The connection of the habits of the individual was an important one. Diseases from habit were distinctly occupational diseases. Cancer was no doubt due to habits of environment. If Dr. Thompson were to pursue this to the end he would have the whole field of human environment and disease included in his subject. Habit entered in almost every instance into the conditions which determined the existence of disease. The view of the subject in this light was extremely impressive.

Dr. JAMES said that there was one group of occupational disease which Dr. Thompson had omitted from his very complete and instructive paper, and which might particularly interest such a group as the members of the Practitioners' Society. In a book, which is probably the first serious work upon occupational diseases, written early in the eighteenth century by Ramazzini, a distinguished Venetian physician, there is an entire chapter devoted to what he calls "The Diseases of Learned Men." In this he quotes from Celsus as follows: "All men of learning and almost all dwellers in large cities suffer with their stomachs."

Dr. THOMPSON said that Dr. Philip King Brown of San Francisco had established the pottery industry for the tuberculous workers in his sanatorium, and that if these industries only were properly conducted they were not detrimental to the health of the individual. He never spoke of occupational diseases without feeling somewhat as did the little girl whose grandmother told her that so many things were "dangerous." At last she said, "Grandmother, you seem to think there is nothing safe but knitting." As to the question of occupational neuroses he had an assistant who was going into the subject of neurasthenia in garment workers and it would be seen what was due to the home and what to the work. Authoritative data were much needed. In some trades, such as those of street sweepers and ashmen, the dust which they inhaled, especially in emptying ashes and other substances, would be supposed to cause bronchial conditions and tuberculosis, but it was not especially prevalent among them, perhaps on account of the open air life. What Dr. Starr said about interesting employers reminded him that when he had been over factories where economic conditions could be bettered by improved protection he had found the employers ready and willing to effect a change. The U. S. Steel Corporation had done wonders in that way. As Dr. Starr said, in the case of typesetters' poisoning, it was no doubt caused by antimony and lead.

Dr. DANA said that Dr. Thompson had interested him two or three years ago in occupational neuroses and he had been following up the subject in his clinic. He had set his assistants to work to investigate and classify nervous troubles related to occupation. The results had been of direct and indirect benefit. There had developed a deeper interest in the matter of environment of the patients and their domestic conditions. A better knowledge of nervous disease was thus secured. One of the assistants, Dr. Leverty, had 400 cases of nervous trouble and was analyzing these on the basis of home and industrial conditions. Such work would be necessary to help us when employers' liability laws and medical insurance laws were enacted, as they would be.

**Keloid Scars of the Face.**—Dr. ABBE presented a case of extreme keloid scars of the face, shown before radium was to be used and to be shown after a year. The patient was a young clothing-cutter who had had acid thrown in his face two years ago. One eye was destroyed and enormously thick scars were spread over the chin, cheek, forehead and nose. Some were the size and thickness of the finger laid upon the skin. For several years it had been demonstrated by Wickham in Paris that keloid scars are reduced by radium treatment and that for true keloid it is a specific. Every surgeon knows that cutting out keloid scars results in redoubling the energy of the tissue and matters are made much worse than before, even if primary union of the scar be obtained or if Thiersch skin grafts be applied. It is therefore a welcome addition to our surgical resources that radium is able to conquer this *bête noir* of the surgeon. The principle of the action seems to be that active cell growth, in the case of true keloid, is killed, and, in the hypertrophic scar keloid an inflammatory irradiation is produced which on subsiding leaves a formed tissue remnant, which undergoes metamorphosis gradually and becomes flatter and softer with time. Dr. Abbe showed photographs of cases now under successful treatment and partially cured; of ugly keloids of the face following herpes zoster which had left distressing red masses resembling high reliefs sculptured on an otherwise fair skin; and of a young girl whose chest was half covered by extreme keloids following the scalding by hot soup; of other cases also over the breast bone in several ladies who had had small keloids cut out with larger ones returning, with the added scar of surgical stitch marks. Except for this new resort surgery has to confess impotence.

Dr. BRYANT said that he had been up against a similar problem and that he congratulated Dr. Abbe on the results achieved. He would certainly not attempt cutting such a mass as in the case presented.

Dr. THOMPSON said that in regard to the keloid of the upper chest there was marked diminution of the pain and the result was most gratifying. He did not know when he had seen a more gratifying result achieved.

Dr. STARR asked if one point of the keloid was exposed to the radium, or if several points were exposed.

Dr. JAMES said he had seen an interesting case at the Presbyterian Hospital, illustrating the constitutional element in the formation of keloid. A colored man who came in for Bright's disease had keloids on his face which had come from little wounds inflicted by shaving; he also had on each arm pretty extensive keloids from vaccination in childhood. He asked if there were any possibility of such an intensive application turning any growth into a malignant growth. Did the closeness of relation of radium rays to *x*-rays, for instance, suggest that malignancy might be produced in the skin?

Dr. ABBE said that the scars showed some results after mild treatment, but that with severer treatment better results followed. In reply to Dr. Starr he said that two liberal applications of a radium plaque would be made on adjacent parts and the sequel would be a marked hyperemia and reaction of a certain quality of inflammation, followed by a speedy subsidence and later whitening of the mass. In reply to Dr. James he said he had never heard of such a sequel and could not conceive of it. Malignant epithelioma of the hands following prolonged *x*-ray work had been shown to be uniformly cured by radium as easily as epithelioma elsewhere.

**Specimen from Unusual Case of Carcinoma of the Stomach.**—Dr. CONNER showed a specimen of carcinoma of the stomach which was presented because it seemed to him to illustrate a point of some importance in considering the question of operability in such cases. The patient, a man aged 55 years, had had mild symptoms of indigestion for two years, but his general health had been good up to four months before his death. Then he began to lose strength and flesh and became very anemic. He vomited occasionally, but had little gastric pain or discomfort. During his stay in the New York Hospital he showed constantly the presence of occult blood in the stools and an absence of free HCl in the stomach contents, together with marked retention of food. Soon after admission a small, movable, slightly tender lump could be felt in the epigastrium which before his death had increased almost to the size of an egg. The patient would not consent to an exploratory operation. Post-mortem showed on the greater curvature, just above the pylorus, a flattened, circular mass about 7 cm. in diameter, the entire central portion of which had been destroyed by ulceration down to the muscular coat. The regional lymph nodes were quite free from involvement and no metastases were to be found elsewhere in the body. Histological examination showed the growth to be a typical example of the special type of adenocarcinoma, known as malignant adenoma. The circumscribed character of the growth and the absence of all metastases made it a singularly favorable one for radical operation. There was a very general feeling, Dr. Conner thought, among surgeons and clinicians that when a cancer of the stomach had reached a sufficient size to be felt readily through the abdominal wall, it usually had involved neighboring structures to such an extent as to make the chance of successful removal very small. On the other hand, among pathologists the fact was well recognized that the large, bulky tumors of the stomach were apt to be of the type of malignant adenoma and that such malignant adenomata in the stomach were not prone to form metastases. It was therefore important for the surgeon and clinician to bear in mind that the existence of a palpable, circumscribed mass of even considerable size was not, in itself, a contraindication to operation, but, on the contrary, might rather be looked

upon as evidence pointing to the probability that the tumor was a malignant adenoma and therefore likely to be suitable for removal. In view of these facts and of the further fact that palpable masses were occasionally encountered in cases of simple ulcer of the stomach or duodenum, the speaker felt that exploratory operation should be resorted to even in apparently unpromising cases.

Dr. EWING said that he agreed with Dr. Conner that bulky tumors of the stomach are usually adenomata which grow to considerable size before invading the lymph nodes. On that account they offer a better surgical prognosis than other forms of gastric carcinoma. This type of tumor does not follow an ulcer, which gives a more diffuse and rapidly infiltrating growth and greater surgical hazards. A third group of tumors produce much mucus, and these, while starting as adenocarcinomata, early infiltrate the wall and may perforate. The same rule applies generally to tumors of the intestine and colon.

Dr. THOMPSON said that one often wished one had advised operation before the patient reached the extreme stage, because cachexia might be so slight with large tumors.

Dr. MEARA said he was one of those ignorant practitioners who were not yet acquainted with the fine distinctions necessary as indications for an operation in such a case. At St. Luke's Hospital a case had come under his care of a patient with a carcinoma at the pyloric end of the stomach. The patient was much reduced and after consultation with two gastroenterologists it was decided that the patient could not stand an operative procedure. At the autopsy a growth was found of the size of a golf ball completely blocking the pylorus of the stomach. The section of this tumor showed so little of cellular tissue that it was difficult to determine that it was actually carcinomatous. The man died of starvation. Had an exploratory operation been done while he was still able to endure the procedure this growth might have been removed and the patient might well have been alive to-day.

## NEW YORK ACADEMY OF MEDICINE.

### SECTION ON MEDICINE.

*Stated Meeting, Held December 16, 1913.*

DR. LINSLY R. WILLIAMS IN THE CHAIR.

**Demonstration of Method of Stretching the Pylorus.**—Dr. MAX EINHORN presented a patient on which he demonstrated his method of stretching the pylorus, upon which he spoke later. The tube had been introduced the night previous and by morning the balloon was in the duodenum. The balloon was then dilated by the attached pneumatic apparatus. If the balloon would not pass through the pylorus after inflation the air pressure was diminished until it would pass. In order to ascertain whether the balloon was in the stomach or in the duodenum an attempt was made to pull it out and if one met with resistance the bulb was in the duodenum; if in doubt the balloon should be filled with air and pulled again. Of course only gentle traction should be used. In this instance it was found that the bulb had not passed into the duodenum, and when this happened it was necessary to wait for several hours longer until it did pass.

**Demonstration of the Introduction of the Modified Duodenal Tube and Gastroduodenal Tube.**—Dr. I. O. PALEFSKI illustrated his method of introducing these instruments. He said that so many men had been working on this problem of the visualization of the upper intestinal tract and so many methods had been devised that if only a part of them were useful they would soon be in a position to know much more than formerly. He had had an experience of 500 duodenal examinations on 25 patients, and had come to regard some of these methods as worthless, some as good, and some as questionable. The *x*-ray was not always satisfactory as a means of visualizing the upper intestinal tract. The fluoroscope was somewhat better. The introduction of the duodenal tube followed by an *x*-ray showing the course of the tube gave a great deal of information. The necessity of being sure that the tube had entered the duodenum before taking an *x*-ray should be emphasized. There were three signs that showed whether the tube had entered the duodenum or not. First, by the duodenal contents; second, by inflation of the intestines, independently of the stomach. If the patient belched on inflation and experienced a great deal of discomfort the tube was still in the stomach. Third, by auscultation. There was a wheezing sound when the tube was in the duodenum. The average time required for the tube to reach the duodenum was from one and one-half to two hours. When the tube reached the second portion of the duodenum one got the typical contents of the duodenum with bile. Dr. Palefski referred to his vacuum bulb which was described in the MEDICAL RECORD some time ago. In introducing the instrument there were three things to be considered. The diameter of the tube must be in proportion to the diameter of the pylorus; the tube must have weight (the tube he was using weighed two and one-half to three times as much as Einhorn's); the time that would be required for the tube to reach the duodenum, and this varied from one to three hours. In introducing the tube the patient assumed three characteristic positions. He first swallowed the bulb while lying in the prone position; he then sat up and the tube was worked in about fourteen inches; then the patient turned on his right side and breathed deeply, at the same time opening his mouth when the tube passed through the lesser curvature and reached the pylorus. The patient was examined on an empty stomach.

**Visualization of the Upper Intestinal Tract by Means of the X-Ray in Conjunction with the Duodenal Tube.**—Dr. I. O. PALEFSKI read this paper.

**Motor Insufficiency of the Stomach.**—Dr. HAROLD BARCLAY presented this paper. He stated that modern investigation had shown that the normal gastric motility was capable of subdivision into three component parts, the correlation of which constituted the normal motor functions of the stomach. They were: 1. The perisystole, by which was understood a concentric drawing together of the stomach so that it adapted itself to its food contents. 2. Peristalsis, or a vermicular series of muscular constricting rings running in the direction of the longitudinal axis from left to right, which action propelled the food from the fundus toward the pylorus. 3. An alternate contraction and relaxation of the pyloric sphincter regulating the output of food, the pylorus remaining tonically closed against the pressure of food until a certain degree of acid gastric juice had been secreted, when the sphincter relaxed and permitted a portion of the acid chyme to escape into the duodenum, when it again closed until this escaped portion of food had been neutralized. A motor insufficiency occurred when there was a loss of equilibrium between the requisite labor and the power of labor, and when the motor power of the stomach was not sufficient to meet the demands made upon it, the viscus discharging its contents only partly and becoming empty only after a long period of time. The two fundamental causes of motor insufficiency were a deficient muscular tone of the gastric muscularis, by which there was either a failure in its perisystole or peristalsis, or both, which was known as atony, or a mechanical interference with the expulsion of its contents. Each of these two conditions represented a distinct clinical entity, the first being purely of a functional nature, while the second, mechanical motor insufficiency, was the expression of a definite organic lesion of the gastrointestinal tract. The condition designated as atony was quite common. It might be hereditary and was frequently encountered after infectious disorders, anemic and cachectic conditions. It was present in neurasthenia and psychasthenia. The simplest form was the insufficient perisystolic tone. Such stomachs, while giving rise to symptoms suggestive of atony, showed no delay in their capacity to expel their food contents within normal time limits. In the normal stomach the ingestion of 30 or 40 c.c. of bismuth mixture did not pass at once to the most dependent portion of the stomach, but remained in the upper one-third and was maintained in tubular form. In the atonic stomach the reverse picture was presented, the food passing at once to the most dependent portion of the stomach. Such stomachs filled like a bowl from the bottom upward. This motor function of the stomach was very important in the digestive process. Normally acid chyme passing through the pylorus excited, through harmones, the secretion of the intestinal and pancreatic juices. It also excited a nervous reflex which closed the pylorus after a certain amount of acid chyme had passed into the intestine. With lessened acidity of the stomach contents it was found that the stomach emptied itself much more rapidly than if the chyme were acid. With hyperacid conditions, on the other hand, the food might be retained too long, and but a small amount of acid

chyme would be tolerated in the duodenum and the duodenal reflex kept the pylorus in a state of spasm. The first of these conditions was well illustrated by functional achylia, in which the stomach emptied itself so rapidly that the intestinal digestion was inadequate to care for the food and a diarrhea was often the result. The symptoms of motor insufficiency depended upon the degree of insufficiency. The characteristic symptoms were a feeling of weight or oppression in the epigastrium following the ingestion of food, and there was a desire to eructate gas; vomiting was infrequent. Physical examination was, as a rule, unsatisfactory. Individuals who presented the enteroptotic habit were very prone to disturbances of motility, and it was among these that one found the pure type of atonic stomach most frequently. The ptosed stomach was not necessarily an atonic stomach, however. Examination of the fasting stomach in the simpler forms failed to show impairment of the propulsive power as a rule, such stomachs emptying within normal limits. In the more marked types examination of the stomach six to seven hours after a meal would demonstrate the presence of food remnants in varying degrees. The test breakfast in atony presented no characteristic picture. The older tests, such as the absorption time of salol, had now been abandoned. The only accurate test for atony was by means of the fluoroscope or the *x*-ray. The second form of motor insufficiency, the mechanical, was the result, as has been said, of some lesion whereby the pyloric sphincter was prevented from dilating to its full extent and allowing a free exit of the food from the stomach. This interference might be intermittent, as in pylorospasm from a chronically diseased appendix or ulcer, or permanent, as the result of inflammatory thickening of the pyloric wall, cicatricial contraction, or adhesions, and tumor growth both benign and malignant. In their earliest conception these cases presented a condition of hypermotility with hypertrophy of the gastric muscularis. The symptomatology of mechanical motor insufficiency was that of the primary pathological condition plus the symptoms due to varying degrees of pyloric stenosis. These were pain, varying in degree and due to different causes as increased peristalsis, food stagnation, or inanition. In the mild cases actual pain might be absent. The symptoms of hypersecretion were in many respects similar to those of the increased peristalsis. With the inability of the stomach to expel its food contents vomiting sooner or later appeared, usually occurring several hours after a meal. According to the inability of the chyme to pass into the small intestine, symptoms of malnutrition developed. The examination of the fasting stomach was of paramount importance in the diagnosis of mechanical motor insufficiency due to obstructive pyloric lesion. After a mixed meal taken between 10 and 11 o'clock in the evening, if the stomach were aspirated nine or ten hours later, it would be found either empty, save for five or ten c.c. of swallowed saliva, or it might show the presence of fasting hypersecretion, with or without any evidence of food remains. The presence of a fasting hypersecretion, that was, any quantity of gastric juice above 30 c.c, was among the earliest evidences of disturbance of motility due to some organic lesion of the gastrointestinal tract, and if it was constantly present it was of great diagnostic importance as differentiating the case from one of simple atony. Dr. William Mayo had called attention to the fact that he had often discovered latent disease of the appendix in persons who seemed to require a gastrojejunostomy and that the removal of the appendix was followed by subsidence of the gastric symptoms. In 53 personal cases of fasting hypersecretion, 29 showed at operation a demonstrable lesion of the gastrointestinal tract, the amount of hypersecretion varying from 30 to 90 c.c. In reviewing 261 cases of simple motor insufficiency, in which over 60 per cent. were complicated by some degree of ptosis, no hypersecretion was found. Evidence of food stagnation might alternate with a pure fasting hypersecretion, as was illustrated by a case which the speaker cited. The test breakfast had not the same diagnostic value as that afforded by the fasting stomach. Its chief characteristic was the large amount of return and the frequent evidences of alimentary hypersecretion. The *x*-ray was also of great value in the diagnosis of mechanical motor insufficiency due to pyloric obstruction or stenosis, especially in the early cases. The principal characteristic was undue retention of bismuth six hours after the bismuth meal, this being far in excess of that seen in simple atony. It was not only essential to recognize the pyloric stenosis, but to determine, as far as possible, the causative factor, and to this end the examination should be exhaustive, including not only the history, physical and gastric examination, but also the examination of the urine and feces. In the early stages of duodenal ulcer there were in many cases distinct evidence of an irritation of the pancreas. It should also be borne in mind that in certain instances latent disease of the appendix and the gall-bladder could produce gastric motor symptoms.

**A Few Illustrations of the Use of the Roentgen Ray in the Examination of the Digestive Tract.**—Dr. H. M. Imboden said that he did not intend to discuss the various phases of *x*-ray examination of the digestive tract, but to show a few illustrative examples of the results obtained. In recent years much had been written about this subject and claims of extraordinary accuracy in diagnosis had been made by several writers. The statements made by different workers had been in many cases conflicting and no doubt much that was in error had been published. The method was of very great value in many cases, but in general the possibilities of obtaining detailed and absolutely positive information concerning all organic lesions of the digestive tract had been much overstated, often through lack of enthusiasm and often through lack of experience. In too many instances the *x*-ray itself had been credited with making a correct diagnosis when in reality the information was obtained from the history, the symptoms, and the physical examinations, and the *x*-ray deductions were based upon these observations. This was true especially in certain well-known continental clinics, where the ordinary routine examination, the history, and the laboratory tests were carried out with admirable skill and the Roentgen technique was from the American standpoint very clumsy and unsatisfactory. The method of making *x*-ray examinations of the digestive tract varied greatly with different individuals. Some were content with the fluoroscopic examination only; others were willing to make a diagnosis on three Roentgen plates with or without screen examination, while others, notably Cole, insisted on making as many as forty to sixty or more plates with no direct fluoroscopy except to accurately place the plate over the stomach area. Dr. Imboden was of the opinion that direct fluoroscopy was of great importance, both for the observation of the ordinary movement of the bismuth through the tract, and also to observe the effect of manipulation of the stomach and intestines through the abdominal wall. The speaker said that he also believed that Roentgen plates were extremely important, both because they showed more detail than could be obtained under any fluoroscent screen and because they were valuable for repeated and continued study, while the screen gave only a fleeting picture. Dr. Cole's plan of making a large number of plates was valuable. The constant changing appearance of the stomach shadow with the passage of the bismuth meal through the tract made it desirable to have a fairly large number of plates. Dr. Imboden said he believed, however, that the number plates might be reduced to comparatively few, if careful fluoroscopic examination was made in addition, and this was his practice at present. Unfortunately the expense of these examinations was essentially large unless the work was limited to a little fluoroscopy or to a very small number of plates. When this was done the information obtained by the *x*-ray alone was correspondingly limited, though taken with the rest of the clinical and laboratory investigation, it might be sufficient. Under these conditions there was always danger of attributing to the *x*-ray plates deductions that really came from other sources and were influenced very little by the *x*-ray. The speaker said he was sorry that he could not as yet be contented with the shortened methods of examination, such as the double meal, proposed by Haudeck, and usually they wished to begin by watching the patient swallow a single bismuth meal and then make observations at intervals for two or three days following, or until the bismuth had passed through the colon. Ordinarily this was supplemented by another examination with bismuth enema. It was to be hoped that in time shorter and simpler methods might be found that would be satisfactory and that the expense of the work might be correspondingly decreased. Although they had in many cases obtained by the *x*-ray valuable information concerning a great variety of conditions affecting the digestive tract, they had often been reminded that the *x*-ray was not an infallible test. With the help of a few lantern

slides Dr. Imboden showed examples of some of the problems of interpretation that confronted the roentgenologist.

**Further Results of Stretching the Pylorus.**—Dr. MAX EINHORN said that the idea of stretching the pylorus had come to him some five years ago. The principle of the method lay in the fact that they could reach the duodenum by allowing the stomach to push what was in it into the duodenum. The apparatus was very simple, consisting of a rubber tube with an attached balloon for introduction into the duodenum and an attached apparatus constructed on the plan of a piston syringe for inflating and deflating the balloon. It was not always necessary to leave the tube *in situ* over night. The balloon would pass into the duodenum in three or four hours in achylia, sometimes even in a shorter time. On the other hand, in many pathological conditions of the pylorus it would take a long time. It was least annoying to the patient, however, to give the tube at night. Fifty or sixty cm. of tubing should be introduced. In some instances it took as long as twenty-four hours for the tube to pass into the duodenum. Dr. Palefski had stated that weight was an important factor in hastening the passage of the tube into the duodenum, but, in his opinion, the weight had very little influence and neither did the position of the patient have much to do with the passage of the tube. The pyloric dilator was first dipped in water and was then introduced past the pharynx and the patient given a drink. The tube was then left over night. The instrument could be used with or without the aid of the *x*-ray or fluoroscopy. When the balloon had reached the duodenum it should be inflated to just that size which could be pulled through the pylorus by gentle traction. Dr. Einhorn said that some time ago he had published the history of 34 cases in which he had used this method and since that time had had others, and the results had been quite good. There was no danger attendant upon this method, so that there was no reason why it should not be practised. He had employed it in about 120 sittings and there had been no bad results. It was a very safe method of widening the pylorus. As to the indications, it was applicable in all cases of pylorospasm in which there was no fresh ulcer. Here stretching was of great benefit and he had seen as striking results as in cardiospasm. If there was an ulcer present, the patient should first be subjected to a course of treatment and the ulcer cured, when one could proceed with the stretching with safety. The method could be used only in benign cases, not in malignant ones. This method was also indicated in beginning stenosis of the pylorus. The question arose here as to how to differentiate between stricture and pylorospasm. In pylorospasm, if the patient was given atropine, the balloon could be pushed through the pylorus at a considerable size, while in real stricture it could not be pulled through, neither could the duodenal bucket be passed. Again, if the instrument could be passed at one time and not at another, it was evident that one was dealing with pylorospasm and not with stricture. The third indication for the use of this method was in advanced stricture in which an operation could not be performed as in aged people or those with heart, kidney, or liver trouble, or where the patient refused operation. If the small bucket would pass then one could push the dilator through, that was a size of about 10 F. This method he had used in advanced cases and it was worth something in these desperate and inoperable cases.

Dr. G. R. LOCKWOOD said that the first paper suggested great possibilities for research work in obscure conditions, but it seemed that the instrument in less skilled hands might possibly inflict traumatism. When the tube was passed for ten to fourteen inches of intestine around angles scratching traumatism could easily be inflicted. Again, if the instrument was passed into the duodenum and, as stated, inflation was apparent through the abdominal walls, in the presence of an ulcer one would be treading on ice. Dr. Lockwood said he did not see how one could diagnose duodenal adhesions through the fluoroscope or the *x*-ray. Dr. Barclay's paper was of peculiar force because of his study of the misconception as to atony and pyloric stenosis due to the fact that physicians failed to examine the empty stomach. The condition of hypersecretion as well as other information could be ascertained from an examination of the fasting stomach and it was important that the examination of the fasting stomach be made rather than that of a test meal. Dr. Imboden's paper was fair and interesting, its *motif* being that fluoroscopy and the *x*-ray were not infallible, but had to be combined with history, physical examination, and symptoms. Personally he felt that in the majority of cases about as much could be learned from the three-plate method as from a series of plates. Dr. Einhorn was to be congratulated on his ingenuity in devising this method of stretching the pylorus, and while he saw its applicability in inoperable cases, one should hesitate a little before employing a measure which acted so far from the field of sight and touch. One should remember that absence of symptoms did not necessarily mean that an ulcer was healed. While there were the slightest suspicions of the possibility of ulcer he would hesitate to use this procedure, but in other conditions it might prove of value.

Dr. CHARLES H. PECK said he, of course, looked upon the subject from the surgical standpoint. The methods of diagnosing and treating these conditions by the duodenal bucket and *x*-ray were interesting, and might be of value in determining the position of the duodenum and the relative position of the stomach. Dr. Barclay's paper on stomach motility, especially the differential diagnosis between atony and mechanical obstruction, was most interesting. However, from the surgical standpoint, pyloric stenosis was a surgical condition and should be treated surgically. Dr. Einhorn's method was applicable in inoperable cases, but pyloric stenosis was a condition that could be treated most satisfactorily surgically and the patients remained well, while after the stretching process it seemed to him there was a possibility of recurrence of the condition. In regard to the group of cases included under pylorospasm, it was rather difficult to decide; the surgeon seldom saw these cases in the early medical stage, and consequently looked upon them as surgical. In those cases of duodenal ulcer and appendicular dyspeptic type it was difficult to form a judgment and examination by the *x*-ray and bismuth and chemical analysis of the stomach contents, as well as a careful examination of the blood and stools should be resorted to when there was doubt as to whether there was duodenal ulcer, pyloric or appendicular disease. It was seldom that they failed to find a lesion somewhere. Negative exploratory operations were becoming fewer and fewer. Dr. Peck said that he was coming to believe that all these methods should be used before resort was had to surgery, but there was a time limit to such investigations and an exploratory operation should be made rather than to allow the patient to drift beyond help. Important assistance was given by bismuth and the *x*-ray in deciding whether a case of cancer was operable or not.

Dr. W. J. WEINSTEIN said that Dr. Palefski's work was very interesting, but he had not done enough to enable one to judge of its real value and it should be corroborated. The combination of the tube and the *x*-ray was certainly an improvement over their old methods. Dr. Barclay's paper was very satisfactory, both from the diagnostic and the therapeutic standpoint, but few cases were so easily diagnosed. Three signs in the diagnosis should be emphasized: 1. The peristaltic waves in the stomach which were the effort of the stomach to propel the food through the pylorus were absolutely diagnostic of obstruction at the pylorus. 2. The presence of sarcinæ indicated the presence of advanced motor insufficiency and might be detected by a certain peculiar, sickening odor. 3. Stagnation or stasis was the best and surest sign of motor insufficiency and was always present in this condition. The normal stomach disposed of a regular dinner in seven hours and one that did not do this, but retained remnants of the meal for sixteen or seventeen hours, was in a state of advanced motor insufficiency and that probably meant obstruction. By means of the stomach and duodenal tubes one could see the real contents of these viscera while by the *x*-ray one could not gauge the quantity of food. Dr. Einhorn had given them many valuable things and it was to be hoped that this method of stretching the pylorus would be as valuable as some of the others. It was possible to cure some cases without stretching and this method did not appeal to him. Divulsion had been abandoned because it was followed by recurrence. A method which had given him good results was that of washing the stomach seven hours after a meal and then not allowing the patient to eat over night. This gave the stomach an opportunity to regain its muscular tone. In motor insufficiency the stomach never got a rest, but if one could give it fourteen or fifteen hours rest it could regain its tone. This would not cure advanced cases.

Dr. L. Pierce Clark said that Dr. Palefski's and Dr. Barclay's papers left nothing to be added. One point in determining motor insufficiency was the readiness with which one could detect the splash. In stenosis of the pylorus one found relatively thick stomach contents as the thinner substances were permitted to pass on. It was marvelous how long the motor function of the stomach would continue good in cases of pyloric stenosis. This was indicated by the marked peristalsis. Occasionally one saw this in marked spasm of the pylorus where there was no absolute obstruction. As to the etiology there was one more factor: undoubtedly stasis was responsible, but there might also be a jejunal angulation.

**Election of Officers.**—*Chairman*, Dr. Joseph C. Roper; *Secretary*, Dr. T. Stuart Hart.

## NEW YORK NEUROLOGICAL SOCIETY AND SECTION ON NEUROLOGY AND PSYCHIATRY OF THE NEW YORK ACADEMY OF MEDICINE.

*Joint Meeting, Held November* 11, 1913.

Dr. Smith Ely Jelliffe and Dr. I. Strauss in the Chair.

**The Irregular Bony Formations of the Sella Turcica in Some Epileptics.**—Drs. L. Pierce Clark and E. W. Caldwell presented a joint paper on this subject, with lantern slide demonstrations. The authors stated that cranial asymmetries and osseous deformities in epileptics had long since been the subject of intensive study by many able investigators. A thickening of the skull, general or in special parts, had been carefully studied by American writers, including Peterson, Sachs, Fisher, Prout, and Clark. In some instances the skull thickenings were very limited in area, forming the exostoses described as osteosclerosis by Binzwanger. Some young epileptics presented a markedly thickened skull, but usually the thickness was increased after the twenty-fifth year and became very marked after the fortieth year. The calvarium of the epileptic was heavier than that of the normal individual of the same age. These facts and others bearing upon cranial thickenings and asymmetries formed a striking part of the literature of epilepsy. Müller, in an examination of the heads of forty-three epileptics, found but four that he considered normal, and it was at once apparent that when we attempted to estimate the importance of the special cranial deformities and variations in epileptics, one entered upon a particularly difficult task. This was especially true when one selected so small a part of the base of the skull as the osseous formation of the sella turcica, a part of the skull which, until very recently, had attracted but little attention. Comparative studies of this region in health and disease were still to be made, and we were soon to face the problem more definitely, and solve its bearings upon epileptic states. The issue would not be so much upon the significance of the relationship which sella deformities might have upon the cerebral content itself, as the bearing the variations had upon the possible alteration of function of the posterior lobes of the pituitary bodies, and the rôle this defect or alteration of function might have upon convulsive disorders of epileptics in particular. Dr. Clark said the very considerable variations of the bony formation of the sella turcica in epileptics was first called to his attention by Dr. Caldwell, who had made a number of *x*-ray examinations in the routine study of the speaker's cases. He believed that Dr. Caldwell's notice was particularly directed to this peculiarity of the sella in epileptics by Dr. Johnston of Pittsburgh, who had not yet published his full study of the subject. The work on the sella and its variations in health and disease by Cuching and others were fairly familiar to all. Three types of the pathologically deformed and enlarged sella had been distinguished and classified by Cushing. The one with which the authors were immediately concerned was associated with thickening of the clinoid processes and dorsum ephippi. Here the enlargement was accompanied by thickening of the walls, but inasmuch as Cushing stated that this type was confined to the acromegalics and gigantics, he believed the bony thickenings were merely a feature of the osseous tendency to overgrowth, which, of course, threw no light on the condition shown in some epileptics. The circulatory disorders in epilepsy shown frequently in slow pulse, vasomotor stasis in the extremities, and, in the speaker's experience, an invariably low blood pressure when arteriosclerosis was not advanced, the tendency to obesity and a ravenous appetite might make one pause before excluding the possibility that there may be some association between epilepsy and a marked disturbance of the pituitary body, and that it might ultimately be found that pituitary disease may sometimes have more or less bearing upon some types of epilepsy in some of its broader and more general manifestations. Certain it was that in so mysterious a disease as epilepsy we had need of the widest possible study in its causation.

Dr. E. W. Caldwell then gave a brief clinical outline, with lantern slide observations, of a few cases of epilepsy showing bony variations in the sella turcica.

Dr. Clark, in reply to a question, said that little or no reference had been made to this condition of irregular bony formations of the sella turcica by those who had made a special study of the cranium, and its significance could only be conjectured. Dr. Johnston of Pittsburgh was the first to suggest that it might have some bearing upon epilepsy, and the treatment of his cases with pituitrin had been followed by rather remarkable results. His own experience with the remedy in epilepsy, Dr. Clark said, had been unsatisfactory.

**Brain Structure According to Age.**—Dr. H. H. Donaldson of the Wistar Institute, Philadelphia, showed a series of lantern slides illustrating changes that occur in the brain according to age. He traced the histological changes from birth to maturity, limiting himself to brains that were normal at birth and free from hereditary taint, the only sources of modifications considered being those represented by deficient nutrition. Slides showing the alterations in the chemical constitution of the brain from birth to maturity, as determined by Dr. Koch, were also presented. The influence of age on the human brain weight was discussed, and a corrected graph for these weights was shown.

**Newer Researches Concerning the Hypophysis.**—Dr. Frederick Tilney of Brooklyn, with the aid of reconstruction models and lantern slide illustrations, gave the results of his recent research bearing upon the development of the hypophysis in man and certain birds and mammals. By this work, which was carried on in the laboratory of Professor Huntington of Columbia University, it was now possible to give an embryological, histological and morphological description of a hitherto undescribed portion of the hypophysis. This portion is known as the pars tuberalis. The ontogenesis of the organ demonstrates the necessity of revising the nomenclature applied to the pituitary body, inasmuch as certain neural and glandular elements have not hitherto been recognized. The study of the development in a number of vertebrate forms is the basis for the following classification of the several parts of the organ: (1) The pars neuralis, consisting of (*a*) the eminentia saccularis of the tuber cinereum; (*b*) the infundibulum; (*c*) the infundibular process. (2) The pars glandularis (epithelial), consisting of (*a*) the paratuberalis (hitherto undescribed); (*b*) the pars infundibularis; (*c*) the pars distalis. Dr. Tilney said the complete report of this research was now in press, and would appear in the *Internationale Monatschrifte für Anatomie und Physiologie*, Bd. XXX.

**Some Causes of Disappointment in Operations on Brain Tumor.**—Dr. William G. Spiller of Philadelphia said the discussion on brain tumor introduced by Bruns and Tooth at the recent International Congress in London called forth some discouraging statements. Bruns said that about 30 out of 100 brain tumors were so situated that a radical operation might be advised; the localization was accurate, and the tumor in these cases was accessible. He believed we might expect surgical success in from three to four per cent. of all brain tumors. Tooth studied the records of 500 cases of brain tumor at the National Hospital obtained during the years 1902 to 1911, inclusive. Of these, about half came to operation. He thought a high mortality was inevitable, but that it could be reduced by a judicious choice of cases and by selection of the operation best suited for individual cases. The immediate dangers common to all growths, all situations, and apparently all operations were shock, collapse, and respiratory and cardiac failure. Dr. Spiller said that many causes of disappointment would occur to any one familiar with operations for brain tumor. The best

known were incorrect diagnosis, the infiltrating character, large size and inaccessible situation of the tumor, errors in technique, and impaired general vitality. While others equally important might be mentioned, the speaker said he desired in this communication to speak of the hyperplasia of the brain caused by tumor, the distortion of the brain, especially from tumor in the posterior cranial fossa, and the acute swelling of the brain, which was probably an important element in the production of hernia cerebri. Increase of intracranial pressure was believed to be the cause of many of the general symptoms occurring with brain tumor, and it would seem from the writings of certain authors that the increase of pressure was attributed directly to the tumor and varied with the size of the growth. There was a condition resulting from tumor to which little attention had been paid, and which was as important, if not more so, than the size of the tumor itself, namely, enlargement of the brain. This hyperplasia was not directly proportional to the size of the tumor; it might be moderate with a large tumor or sufficient to cause much enlargement of one cerebral hemisphere where the tumor was small. The hyperplasia might be the result of irritation either from pressure, or possibly from some substance elaborated by the tumor, and was caused by an overgrowth of neuroglia tissue. The condition was not unknown in medical literature, although little was said concerning it. This hyperplasia of the brain might occur with any variety of tumor, and was not confined to glioma. It should not be confused with enlargement from glioma tissue, for it had not the appearance, microscopically, of tumor, nor should it be confused with the acute brain swelling of Reichardt. The sudden fatal termination that occurred in some cases of tumor was probably the result of this enlargement of the brain, and of interference, by the general increase of intracranial pressure, with the important functions of the medulla oblongata. It might also be that hyperplasia of the brain was an important cause of impairment of mentality in some cases of brain tumor. Distortion of certain parts of the brain was a grave complication of tumor. The displacement of the cerebellum and the occipital lobes complicated the operation, and sudden relief of pressure probably had injurious effects on parts that had been distorted gradually. Cranial nerves in the region of the medulla oblongata were liable to be stretched gradually by such distortion, and the effect of this stretching on the pneumogastric might be serious. Hernia cerebri was a serious complication of brain tumor. Where it resulted from decompression it had been supposed to be indicative of the degree of intracranial pressure and to show to what extent the pressure had been relieved. This view was not entirely correct, as such a hernia may develop in cases where there had been no decided increase of intracranial pressure. A hernia may cause pressure against the edges of the opening in the skull, with occlusion of vessels and softening of the part of the brain implicated in the hernia, causing in this way hemiplegia and other grave symptoms. In connection with his paper, Dr. Spiller showed a number of lantern slides illustrating this condition of hyperplasia of the brain, with enlargement of the hemisphere, complicating brain tumor. Also pictures of distortion of the brain caused by tumor.

Dr. M. Allen Starr said he had seen a number of cases of brain tumor associated with a distinct hypertrophy of the corresponding hemisphere, but he had never ascribed to this condition the novel and very interesting explanation offered by Dr. Spiller, nor could he recall any reference to it in the literature. The form of hypertrophy that followed operation in some cases and failed to occur in others had often puzzled him: he could not understand why in some cases after an operation for brain tumor there should develop an enormous hernia cerebri, while in other cases it was entirely absent, and he did not believe that it was always an evidence of sepsis. The distortion of certain parts of the brain resulting from tumor was a well recognized fact, and by causing pressure upon or stretching the cranial nerves it might give rise to secondary symptoms and obscure the diagnosis. Dr. Starr said that a review of his last fifty cases of brain tumor seen in private practice showed that the diagnosis as to the location of the growth was possible in thirty; in the remaining twenty, its location could not be definitely determined. In twenty of the fifty cases, an operation was urged, and in eighteen of these it was actually performed. In eleven of the eighteen the operation confirmed the diagnosis, and the tumor was removed; in two the tumor was found, but could not be removed on account of difficulties encountered in connection with the operation; in five, nothing was found. The death rate was six per cent.

Dr. B. Sachs said that while doubtless many had observed this hyperplastic enlargement of the hemisphere accompanying brain tumor, he thought Dr. Spiller was wise in attempting to lay stress upon it. Referring to the causes of disappointment in operation on brain tumor, Dr. Sachs said that at the recent International Congress in London Sir Victor Horsley made the statement that unless the diagnosis was made before the appearance of optic neuritis, which was generally regarded as such an important feature of the condition, it was almost too late to do the patient any good. This, Dr. Sachs thought, was rather an extreme view; in the recognition of this condition, it was not an easy matter to forego the advantages that went with the presence of a pronounced optic neuritis, and he could recall a number of instances where the diagnosis, without the eye symptoms, would have been practically impossible. In a case that was recently under his observation there was no optic neuritis, but there was evidence of tumor involvement of the fifth nerve. In addition to this, there were marked cerebral symptoms and an operation was contemplated, but after three weeks' observation in the hospital and under simple hygienic treatment all the symptoms gradually disappeared with the exception of the fifth nerve involvement, and the patient had been temporarily discharged. Dr. Sachs said he still believed that here they had to deal with a brain neoplasm, but the patient was so much better that the idea of an operation had been abandoned for the present, at least. In their work at the hospital during the past year, *x*-ray plates of the cranium had been carefully studied with regard to possible changes in the formation of the sella turcica in the presence of certain brain lesions; their results, however, had proven of no practical value and were about as negative as those reported by Dr. Clark tonight in connection with epilepsy. The high mortality accompanying operation for brain neoplasms might perhaps be lessened to some degree by a more careful manipulation of the brain. The most gentle manipulation and the rapid checking of hemorrhage he regarded important factors in the reduction of the death rate after these operations.

Dr. Robert Abbe said he was quite in accord with what had been said in regard to the disappointments attendant upon operations for brain tumor, and he had practically come to the conclusion that decompression was the operation of choice, both on account of its comparative simplicity and the benefits that accrued from it. He had in mind several instances where this procedure was followed by great prolongation of life, together with improvement in the eye symptoms. In one case where no tumor was found, although that diagnosis had been made and was well founded, the patient survived a decompression operation for four or five years and has resumed work. In another case where the sight had been entirely lost, the decompression resulted in restoration to health, and the patient was alive three years after the operation, when she was lost sight of.

Dr. J. Ramsay Hunt said that in common with others he was familiar with the enlargement of the convolutions and parts of the hemisphere in the neighborbood of brain tumors, and that he had always regarded it as the result of stasis due to an interefernce with the circulation, near the growth, of the blood and lymph streams. A similar condition was observed in abscess formation of acute onset, and under those circumstances the term hyperplasia was certainly scarcely applicable. The speaker said he would be inclined to attribute this swelling and enlargement to a chronic stasis and edema, and not to a true hypertrophy or hyperplasia of brain tissue. That in old cases, as a result of pressure and stasis, there should be some changes in the appearance and relation of the histological elements was not surprising, but certainly in his experience there had been nothing in the microscopic picture of the swollen region that would have suggested the occurrence of hypertrophy and hyperplasia.

Dr. Walter Timme said that in the May (1913) issue of the *Journal of Nervous and Mental Diseases* he had published an article giving the results of some observations, made in Dr. McCallum's laboratory, which perhaps might throw some light on this subject. The experiments were in connection with artificial nerve

pressure, produced by tying the vagus nerve above the diaphragm enough to cause pressure, but without severing the nerve. It was found, upon killing the animals four or five months later, that there was a remarkable hyperplasia in the glands of the wall of the stomach. The number of glands of the stomach was increased from 5,000,000 in the normal cat to over 9,000,000 in the operated animals. When both vagi were treated in this way, the hyperplasia of the glands was more pronounced. There was perhaps some analogy between this condition and the hyperplasia of the brain tissue observed by Dr. Spiller in connection with the pressure produced by brain neoplasms.

Dr. CHARLES A. ELSBERG said that he had also noticed this asymmetry between the size of the two lobes in cases of brain neoplasm, and had ascribed it to an increase of the fluid content on the affected side. He did not understand whether Dr. Spiller attributed the occurrence of hernia cerebri to this hyperplasia. In many cases of hernia cerebri, the protrusion could be reduced by elevation of the patient's head or by lumbar puncture or by aspiration of the ventricles or the corpus callosum, or by a combination of these methods. The speaker called attention to the varying degrees of pressure that existed in these cases: thus at times we had a large, tense hernia occurring without apparent explanation, while at other times the protrusion might be almost collapsed, and if it was attributable to this condition of hyperplasia it would be difficult to understand these marked differences in the pressure. Dr. Elsberg said that within the past few years he had seen two cases of tumor in the left frontal region, both located in the cortex and of the endothelial type, where the wrong side of the brain was exposed. In both of these cases there was no increase in pressure; on the contrary, there was a diminution to such a degree that it led to a subsequent opening of the skull on the opposite side, where the tumor was really located.

Dr. FOSTER KENNEDY asked Dr. Spiller if by hyperplasia he really meant an increase in the brain elements or whether he referred to an edema of the brain. In the more acute types of rapidly growing gliomata, edema seemed to be the largest factor. He also inquired whether the reader of the paper regarded this edema or hyperplasia extending to a point some distance from the growth as a misleading factor in the diagnosis of brain neoplasms. Personally, he had always thought that the edema produced by a brain tumor varied inversely with the distance from the tumor and that the symptoms would correspond with the lines of pressure radiating from the tumor. Dr. Kennedy then described two cases of expanding cerebellar lesions producing much edema, and consequent equivocal diagnostic signs which, however, were the result not primarily of the edema, but secondarily of the intense medullary and pontine distortion and constriction of unusual tracts by the foraminal ring.

Dr. SPILLER, in closing, said that in his paper he did not discuss edema of the brain. That was an entirely different process. He spoke of hyperplasia, which referred to an overgrowth of the neuroglia tissue. In these cases, as shown by the microscope, there was little or no increase of the neuroglia cells, but sometimes proliferation of the neuroglia fibers could be demonstrated. The hyperplasia possibly was caused by chemical changes resulting from some substances elaborated by the tumor; but more likely from irritation by the tumor. It was probably not the cause of hernia cerebri and should not be confused with edema or acute swelling of the brain, which probably have some relation to hernia. This hyperplasia may extend for a considerable distance beyond the limits of the tumor, and possibly may be in part the cause of the symptomatology of brain growths. We know that a tumor of the brain may be removed at times in its entirety, and yet the symptoms may not entirely disappear, and possibly this persistence of symptoms may be attributed to alteration of nerve cells, to hyperplasia, or other changes. The same was true after a decompression operation. The mere relief of pressure does not usually remove all the symptoms, and the speaker said he had known the condition to be aggravated by a decompression. He had shown lantern slides of a brain in which a very small subcortical tumor of the parietal lobe had caused great enlargement of the cerebral hemisphere of the same side. It would be unreasonable to attribute the hyperplasia in this case to stasis and edema of the brain. Such conditions as these described, Dr. Spiller said, were the causes of many disappointments in operations upon brain tumor.

### PATHOLOGICAL SOCIETY OF PHILADELPHIA.

At a stated meeting held December 11 Dr. ALFRED GORDON presented a specimen of "Anencephalia." The fetus was obtained from a woman who had had several miscarriages, and whose husband, previously of good habits and free from evidences of syphilis, and with a negative Wassermann reaction on the part of his blood and cerebro-spinal fluid, had become addicted to periodical excess in the use of alcohol, conception in each instance taking place during such a period.

Dr. GEORGE W. OUTERBRIDGE presented specimens as follows: (1) "Carcinoma of the Ileo-cecal Valve, with Intussusception of the Ileum into the Ascending Colon"; (2) "Multiple Cysts of the Omentum"; (3) "Papillary Carcinomatous Cyst of the Parotid Gland."

Dr. W. H. F. ADDISON demonstrated "The Frankfort Method of Mounting Microscopic Specimens on Gelatin, without Cover-glasses." A ten per cent. solution of the finest photographic gelatin, carefully filtered, is employed, and it is especially available where stains in aqueous solution are used.

Drs. ERNEST H. GOODMAN and J. STUART RODMAN presented "Heart and Pericardium from a Case of General Septicemia." The patient was a boy with a reddened swelling of the leg, which was found to be due to osteomyelitis and was incised, with negative result. Subsequently, additional swellings appeared at the ankle, and when excised yielded pus. At a later period signs and symptoms of pericarditis, pleuritis, and pneumonia developed. Pericardotomy was performed, and 1050 cu. cm. of pus evacuated. Drainage was provided for, but death resulted from hemorrhage, as a result of erosion by the drainage-tube of the internal mammary artery.

Dr. F. D. WEIDMAN exhibited a specimen of "Congenital Stenosis of the Arch of the Aorta." The patient had been a colored man, 35 years old, who had died from acute edema of the lungs. The autopsy disclosed a narrow coarctation of the descending aorta.

Dr. E. D. FUNK demonstrated specimens of tuberculosis of the mesenteric glands and of the thoracic duct.

Drs. A. I. RINGER and E. M. FRANKEL presented a communication entitled "Studies in Diabetic Acidosis."

Drs. O. H. PERRY PEPPER and T. G. MILLER presented a paper entitled "Report of Culture of Plasmodium of Malaria by Bass' Method," and they demonstrated a number of illustrative specimens. While the investigations were not highly successful, they opened the possibility of obtaining information as to the mechanism of malarial hemoglobinuris and of studying the influence of drugs in the treatment of malarial conditions.

## Books Received.

*The* MEDICAL RECORD *is pleased to receive all new publications which may be sent to it, and an acknowledgment will promptly be made of their receipt under this heading; but this is with the distinct understanding that it is under no obligation to notice or review any publication received by it which in the judgment of its editor will not be of interest to its readers.*

RESEARCHES ON RHEUMATISM. By F. J. POYNTON, M.D., Lond., and ALEXANDER PAINE, M.D., D.P.H. Illustrated; cloth; price, $5.00 net; 461 pages. The MacMillan Company, New York.

CUNNINGHAM'S TEXT-BOOK OF ANATOMY. Edited by ARTHUR ROBINSON, M.D., F.R.C.S. Ed. Fourth Edition, Enlarged and Rewritten. Illustrated; cloth, price $6.50 net; 1596 pages. William Wood and Company, New York.

MEDICAL AND SANITARY INSPECTION OF SCHOOLS, For the Health Officer, the Physician, the Nurse and the Teacher. By S. W. NEWMAYER, A.B., M.D.; 318 pages. Illustrated; cloth; price $2.50 net. Lea and Febiger, Philadelphia and New York.

INTERNATIONAL CLINICS. A Quarterly of Illustrated Clinical Lectures and Especially Prepared Original Articles on Treatment, Medicine, Surgery, Neurology, and Other Topics of Interest to Students and Practitioners. By Leading Members of the Medical Profession Throughout the World. Edited by HENRY W. CATTLE, A.M., M.D. Price $2.00; cloth; illustrated; 312 pages. J. B. Lippincott Company, Philadelphia and London.

MENINGOCOCCUS MENINGITIS. By HENRY HEIMAN, M.D., and SAMUEL FELDSTEIN, M.D. With Introduction by HENRY KOPLIK, M.D. Illustrated; cloth; price $2.50; 313 pages. J. B. Lippincott Company, Philadelphia and London.

Transactions of the American Otological Society. Forty-sixth Annual Meeting. Hotel Raleigh, Washington, D. C., May 6 and 7, 1913. Volume 13, Part 1. Paper; illustrated; 252 pages. Mercury Publishing Company, New Bedford, Mass.

Progressive Medicine. Edited by Hobart Amory Hare, M.D. Assisted by Leighton F. Appleman. Volume 15, No. 4. Paper; price $6.00 per annum; illustrated; 411 pages. Lea and Febiger, Philadelphia and New York.

The Supposed Death Rates of Abstainers and Non-Abstainers and their Lack of Scientific Value. By Edward Bunnell Phelps, M.A., F.S.S. Reprinted from *The American Underwriter Magazine and Insurance Review* Vol. XL, No. 1 (July, 1913). Cloth; 30 pages. Thrift Publishing Company, New York.

Pyorrhea Alveolaris. By Friedrich Hecker. B.Sc., D.D.S., A.M., M.D. Illustrated; cloth; price, $2.00: 157 pages. C. V. Mosby Company, St. Louis.

Science and Education. A Series of Volumes for the Promotion of Scientific Research and Educational Progress. Edited by J. McKeen Cattell. Volume II—Medical Research and Education. By Various authors. 536 pages; cloth. The Science Press, New York and Garrison, N. Y.

Fruchtabtreibung und Praventivverkehr im Zusammenhang mit dem Geburtenrückgang. By Dr. Max Hirsch. Paper; 267 pages; price, 6 Mks. Curt Kabitzsch, Wurzburg.

Causes and Cures of Crime. By Thomas Speed Mosby. Illustrated; cloth; price, $2.00: 354 pages. C. V. Mosby Company, St. Louis.

Case Histories in Pediatrics. By John Lovett Morse, A. M., M. D. Second Edition. Cloth; illustrated; 639 pages. W. M. Leonard, Boston.

Die Heliotherapie der Tuberculose. Von Dr. A. Rollier, Legion mit 138 Textabbildungen. 119 pages; price, 6.60 Marks. Julius Springer, Berlin, 1913.

Dysenteries, Their Differentiation and Treatment. By Leonard Rogers, M.D., F.R.C.P., B.S., F.R.C.S., C.I.E., I.M.S. Cloth; illustrated; 336 pages; price, $3.75. Oxford University Press, New York.

The Principles and Practice of Medical Hydrology, Being the Science of Treatment by Waters and Baths. By R. Fortescue Fox, M.D., F.R.Met.Soc. Cloth; 295 pages; price, $2.00. Oxford University Press, New York.

Surgical Experiences in South Africa 1899-1900. Being Mainly a Clinical Study of the Nature and Effects of Injuries Produced by Bullets of Small Calibre. By George Henry Makins, C.B., F.R.C.S. Cloth; illustrated; 504 pages: price, $3.75. Oxford University Press, New York.

A Manual of X-ray Technic. By Arthur C. Christie. Illustrated; price, $2.00; cloth; 104 pages. J. B. Lippincott Company, Philadelphia and London.

Das Chronische Partielle Herzaneurysma. By Dr. Maximilian Sternberg. Paper; illustrated; 76 pages; price 3 marks. Franz Deuticke, Leipzig und Wien.

Theorie und Praxis der Inneren Medizin. By Dr. Erich Kindborg. Volume 3: cloth; illustrated: 751 pages S. Karger, Berlin.

Die Wassermannsche Reaktion. By Dr. Harald Boas. Paper: 242 pages; prices, 8.80 marks. S. Karger, Berlin.

Die Geschwülste der Hautdrüsen. By Prof. Dr. G. Ricker and Dr. Johannes Schwalb Paper; price, 10 marks; illustrated; 240 pages. S. Karger, Berlin.

Praktische Winke fur die Chlorarme Ernährung. By Prof. Dr. H. Strauss. Paper; price, 1.50 marks; 63 pages. S. Karger, Berlin.

Archiv fur Experimentelle und Klinische Phonetik. Herausgegeben von Prof. Dr. J. Katzenstein. Volume 1, Part 1; price, 24 marks; 116 pages. S. Karger, Berlin.

Lietfaden der Hygiene. By Dr. Aug. Gärtner. Paper; illustrated; 676 pages. S. Karger, Berlin.

Taschenbuch der Therapie. Herausgegeben von Dr. M. T. Schnirer. Cloth; price, 2.50 marks; 474 pages. Curt Kabitzsch, Wurzburg.

Klinik fur Psychische und Nervöse Krankheiten. By Robert Sommer. Vol. 8, Part 2; price, 3 marks; paper; illustrated. Carl Marhold, Halle a. S.

Klinik fur Psychische und Nervöse Krankheiten. Herausgegeben von Robert Sommer. Paper; vol. 8, part 3. Carl Marhold, Halle a. S.

The Physician's Visiting List for 1914. Leather; price, $1.00 net. P. Blakiston's Son & Company, Philadelphia.

The Medical Record Visiting List or Physicians' Diary for 1914. Newly revised; leather; price, $1.50. William Wood & Company, New York.

## Miscellany.

**The Doctor in Art.**—W. Sampson Handley states that the late Sir Seymour Haden, founder and President of the Royal Society of Painter Etchers, the leader, along with Whistler, of the revival of etching in England, and one of the greatest exponents of the art, was a surgeon, and no mere dilettante one, for he had studied not only in London but also in Paris and Grenoble, he had obtained the Fellowship of the College of Surgeons, and he had practised as a surgeon until the age of 52. He considered etching rather as a recreation than as the serious business of his life, so that his etched plates number only about 200 in all. Perhaps he gave too much of his life to medicine. If his art had been the single passion of his life he might have been the English Rembrandt. But he had that sanity and love for a balanced life which has often characterized gifted Englishmen, and he refused to become the slave of his genius. The same struggle and the same victory is exemplified in the career of Robert Browning, who managed to become a poet, and a great one, without ceasing to be a man of the world. Mr. Henry Tonks, assistant professor at the Slade School of Fine Art, is another instance of the doctor turned artist. Many generations of students have felt for him the affection not unmingled with wholesome dread which Sir Henry Morris used to inspire. Deeply interested in his work and his students he will permit no slack worship at the shrine of Art.—*Lancet*, October 4, 1913.

**Breakfast and Brainwork.**—In an editorial article in the *Lancet*, September 27, 1913, it is pointed out that, as the evidence of some literary men proves, there is no time of day more fitted for the production of intellectual or imaginative work than the early morning hours. A little fresh-air exercise to start the day, following the habit of some athletes in training, is a thing that many a professional or business man might cultivate with advantage, but his breakfast should often be lighter than that of the average individual. There is a great deal to be said in favor of the "coffee and rolls" plan, and for men whose day is spent in work which taxes the brain and nervous system generally more than the muscles, the wise course is to relegate anything approaching a hearty meal to the period of relaxation, the evening. But that part of the continental system which involves the eating of a heavy lunch is as objectionable as the heavy breakfast plan. It can be excused only if adequate time is given after the meal for the digestion thereof, and most professional and business men cannot spare the hour's ease which should follow a hearty midday meal. In most European cities where the midday meal is a heavy one an hour or so is commonly spent in smoking and chatting afterward. This leisurely proceeding, however, is not possible with the more strenuous business habits of England and America, as the "quick lunch" institution testifies. Nor need the quick lunch be severely deprecated if the quantity of food ingested is reduced in accordance with the time taken for its consumption. If the quick luncher is also a heavy luncher then he combines the evil properties of both the continental and English methods, and will, doubtless, incur the punishment of the dyspepsia which his habits invite. But if the meals during the day be light the writer does not believe that the worker need be asked to forego either breakfast or lunch.

### TREATMENT OF RETRODISPLACEMENTS OF THE UTERUS.*

By W. M. POLK, M.D.,

NEW YORK.

Retrodisplacements are so often free from vexatious symptoms that many look upon them as mere anatomical freaks, to be let alone as long as the deformity lets the patient alone. This is no doubt good practice in many instances, notably, congenitals, and in the unmarried.

Marriage introduces elements of congestion which sooner or later cause symptoms of distress. The same may be said of pregnancy and of the parturient state. These symptoms hover around the uterus and its appendages, but, in my experience, come more directly from the body of the uterus. There are more or less pelvic pain and discomfort, and, in some cases, women with susceptible nerves are prone to irritability, pessimism, and phases of hysteria. Naturally in such a person, an elongated, painful fundus in Douglas' culde-sac is not helped by marital contact. If such composite misery can be traced to a retroverted uterus it must be treated. How? Before operative work was rendered safe by present day methods, pessaries were somewhat in vogue in these cases, but the safety with which operations might be applied has so far driven that remedy from the field. It now is rarely heard of, yet it is very valuable, especially if we remember that no one form of operation has so far established itself as the one procedure to be universally applied. There are too many of them offered to insure confidence in any one. Why not give the pessary a place in the field of contention? If so, I have an idea its quota of cures will rank with several operations, and this, too, without arguing in its favor the unfavorable liabilities attached to some of the latter. The treatment cannot be applied promiscuously to-day any more than it could in the period of its popularity; only certain cases are available.

The higher the attachment of the vaginal wall to the posterior face of the uterus, the greater the purchase on the organ, and the more certain the relief. Of course the uterus must be movable, not adherent; if adherent it should be previously freed through posterior vaginal incision, followed by fitting of the pessary then and there. The simplicity of this procedure and its safety remove it from the domain of such major procedures as constitute any one of the operations for retrodisplacements.

Given favorable conditions the most aggravated cases of this disorder can be cured by pessary. An important necessity to this cure is proper involution of the uterus. Whatever exists as a hindrance to this must be removed before satisfactory results can be obtained; for instance, a big cervix, torn or much hypertrophied, must be gotten rid of by operation; not by amputation, if avoidable, because this will lower relatively the vaginal attachment to the posterior wall of the cervix of the uterus and lessen efficacy of the pessary. Certain cases which from long continuance have acquired thickened endometria, can only be involuted by curettage and immediate packing, the latter to provoke contraction. It should be done but once and removed in twenty-four hours. It is obvious that the pessary must have a resting place, making obligatory a thorough repair of the ruptured or chronically relaxed and over-strained pelvic floor; the more perfect this is the more satisfactory the work of the pessary.

I am afraid you will all laugh, if, after this laudation of the treatment by pessary, I turn round and say, "But I have an operation to recommend to you." I suggest, however, that it be only used if the pessary fails. The symptoms found with retrodisplacements depend upon venous congestion and consequent swelling of the uterus—the absence of this gives you the deformity but without the distress. Fact and theory show that traction upon and some twisting of the veins is the gross ultimate element in this congestion. Remove this and even without getting an ideal position for the uterus you relieve your patient.

I will not bore you by detailing the defects of other operations devised for this difficulty, but at once put before you the one I am trying so far with good results.

In a few words, it is an operation which deals directly with that peritoneal covering of the pelvic floor which is in closest contact with the lower parts of the uterus. Analysis of these displacements shows that the cervical setting of the uterus is lowered and carried forward by the downward and forward movement of the front sections of the floor. Correct this and you strike at the root of the difficulty.

The method of correction is as follows: Take up the slack tissue between the uterus and the bladder by folding it in along a line running from the bladder to and through the area of loose attachment of peritoneum to the anterior face of the cervico-uterine region. Take up as much as you can without undue tension. Use, if necessary, two rows of sutures, one outside the other. To determine the exact line of attachment of bladder to vagina, which is the line at which you begin the infolding, draw the uterus well up, so as to put all the parts on the stretch. After the infolding has been accomplished shorten the posterior and lateral attachment of this lower part of the uterus by encircling them with one or more sutures, treating each side separately.

*Read at the Two Hundred and Fifty-eighth Meeting of the Practitioners' Society of New York.

The process is accomplished as follows: Thrust the extended figures into the cul-de-sac, push the uterus forward and upward, locate the uterine artery, pass a suture from before backward, a finger's breadth above the artery and half an inch from the uterus, so as to emerge half to three-quarters of an inch from the uterus, just below the uterosacral folds. Return over this fold through the intervening tissues, about quarter of an inch above the point of entry, alongside the uterus. For anchorage carry this end of the suture through the antero-lateral face of the cervical tissue, and tie. At least two such sutures should be used on each side.

## SOME OBSERVATIONS UPON THE ETIOLOGY OF MENTAL TORTICOLLIS.*

By L. Pierce Clark, M.D.,

New York.

Not the least important fact brought out by the modern analysis of mental disorders is the enormous significance of a closer study of infantile life. A few years ago it was thought that little or no mental data bearing on the after-life was taken up by the child before five or six years of age. It has

Fig. 1.—Front view of E. K. before treatment, showing torticollis.

been conclusively proven to most of us, however, that it is precisely the early childhood that is most important in the formation of physical and mental habits. From a neurologic and psychiatric standpoint the nursery life of the child is of greatest importance in determining the trends that in later life make for safe voyaging or mental shipwreck. To many the above statements may appear more or

Fig. 2.—Side view of E. K. before treatment.

less trite and commonplace, but at the risk of restating the obvious, I wish to call attention to these views with the hope that studies of the infantile mental life may be a matter of more frequent report in our study of the neuroses and psychoneuroses. As the latter class of nervous disorders make up the major portion of neurologic practice, the practical value of these remarks is evident.

If it be true that tics are rare in mental defectives of the feebleminded class and habit movements* are extremely common in this type, in fact, exist in some form in almost every case of non-apathetic idiocy and imbecility, then it would seem to follow that the types of individuals in which tics appear are afflicted with the mildest type of mental inferiority and psychoneurotic tendencies, and such individuals possess a unidefect instead of a polydefect, by which latter term some eugenists designate the mental state of feeblemindedness.

In the light of deeper researches in the origin of tics it is interesting to note that much of the modern literature on the real nature of tics are

*Read before the N. Y. Neurological Society, December 2, 1913.

*"A Study of the Significance of Habit Movements in Mental Defectives," L. Pierce Clark and Charles E. Atwood, *Jour. A. M. A.*, March 23, 1912, Vol. LVIII, pp. 838-843.

excellent examples of specious casuistry, as illustrated in the first and obvious origin in my own case. The alleged causes of tics run a parallel course with those assigned to all the psychoneuroses and even to the etiology of many obscure organic

Fig. 3.—Condition of practical recovery from the torticollis as seen in Figs. 1 and 2. The dropping and atrophy of muscles of the right shoulder are due to the nerve resections.

disorders. In this category epilepsy, a true organic disease, was formerly arraigned. The hardest death to die in the category of causations of all the functional neuroses has been the reflex one; the indictment of eye, nose, and throat disorders has held on for centuries; more than vestiges of some of the reflex causes for the neuroses still remain, as notably shown in the articles still indexed under eye strain. However, the steady enlargement of the importance of mental infantilism in the tics as first urged by Brissaud points the way of escape from the reflex obsession as a real causation of head and face tics. It seems a pity that the brilliant work of Janet in this and kindred fields of the etiology of the psychoneuroses should have really stopped short in the final pursuit of tic symptoms to their genetic origin and their real rôle in developing the mental and physical habits in the individual.

It is both interesting and pathetic that the majority of ticeurs are usually the last to recognize the abnormality of their tic movements. The point is, however, not without parallel in other parts of the psychoneurotic field, notably among those afflicted with lisping and other speech delinquencies as well as the simpler sort of obsessive and compulsive acts that rarely attain to the dignity of a distinct nervous disorder. That these peculiarities of manner and behavior are a real and integral part of the personality are not the least evidenced by the ready defense or excuse for them the possessor makes when they are brought to his individual notice. The intensity of emotional feeling he shows, and the quick animosity stirred by the discussion of these defects or attempt at their removal, beshew that the individual's real psyche and personality have been ruthlessly approached or handled.

In resolving the tic movement back into its simpler terms of origin, I have been struck with the fact that nearly every accessible case susceptible of analysis has shown that the tic is only a further elaboration of a habit movement which, as a crude symbol, still endures and furnishes an important and deep-seated satisfaction to the individual's real psyche. In order to make a clear-cut issue of the above introduction, I shall confine my remarks to a particular type of tic usually designated as mental torticollis.

It matters little for the purpose of this short discussion whether all types of torticollis are classed with pure spasm or whether some of them are tics in their real nature, as I shall confine my remarks to that sort of muscular spasm of the spinal accessory distribution which behaves like a

Fig. 4.—Back view of E. K. showing practical recovery from the torticollis.

tic in that it is a reflex, defensive or voluntary movement which has assumed an imperative character, has been long enduring and is not of simple reflex origin nor of the rheumatic type. Overlooking, therefore, the confusion in the exact classi-

fication of the variation of types of spasms and tics that exist in literature, one is impressed that some ordinary spasmodic disorders behave like tics and others like true spasmodics. This fact is especially true of ordinary torticollis, upon which the above question is most mooted. However this may be, careful and repeated examination of torticollis proves that many such have their essential origin in a defective ideation or in a mixed neuropsychopathic constitution just as have the true tics. The essential causation in many cases of spasmodic torticollis is as truly mental as the pure tics. Both at such times have the same general character of movement or involve the same neuromuscular apparatus with bizarre movements. All who look most carefully into the psyche of torticollitics are more and more impressed that all torticollis is preponderantly or wholly of psychic origin, especially in those cases where gross nerve lesions can be excluded. It is as a contribution to this latter contention that this thesis is made. I desire to make the general statement, that torticollis is in the majority of instances a benevolent excess of functioning of which we do great harm to suppress or rid the patient, and, considered purely as a help mechanism, it should not be removed until the real cause is abolished; failing in this task, the torticollis should be allowed to continue. We then should strive to make the individual as comfortable as possible in the enjoyment of his excrescence of function. Every ticeur comes in time to believe this doctrine, just as firmly as it is ordinarily denied by many physicians. It may be said as a sort of medical irony that Nature fights silently but effectively with the patient against all our usual efforts to abolish the tic, and in consequence a torticollis temporarily eradicated or suppressed usually returns or endures in spite of all treatment. Heretofore the tic disorders have been the bane of our neurologic lives and one rarely sees a complete cure.

If one believes that mental torticollis or tic is not solely an excess of physiological habit but that it has profound and intimate association with the full depth of the patient's real psyche, and that the act is laid down or flows out of the deepest needs of that particular personality, the importance of the continuance of the tic movement is obvious. We thus will learn to treat such disorders with the gravity and deference they really deserve. Much and more of what I have already pointed out will receive illustration by citation of a case I have intensely analyzed for the past two years. I shall point out only the salient features of the case and give the summary conclusions of the study. While the future treatment of torticollis may not be essentially more hopeful as to cure, it is safe to say that further research is bound to give us a radically new and more complete knowledge of its origin and the reason why it is not more often cured. We shall be no longer content to take refuge behind the statement that its real nature is inaccessible because the patient happens to be a psycho- or neuropathic individual.

My case is as follows:

E. K., a single man of 34 (bookkeeper) was referred to me two years ago for study and treatment by Dr. Reginald Sayre of New York City, as suffering for the past three years from a severe degree of spasmodic torticollis of the tic type which had defied all lines of treatment, even to that of full nerve resection of the spinal accessory; which was done at my request.

Aside from some degree of neurotic instability in the patient's immediate family (brothers and sisters) and a moderate degree of alcoholism in the father, who died of Bright's disease, the family history was negative. The patient suffered from no physical defect aside from a gradually increasing and severe left-sided spasmodic torticollis. This disorder had been present for several years and of late had gradually involved the splenius and trapezius muscles as well. The type of movement in this torticollis is well shown in the photos which Dr. Sayre has kindly lent me for this presentation, and is of an only too common type for detailed description here. I shall pass over the inhibitional and medicopedagogical training which was most intensively followed up for a year, which treatment only ameliorated the torticollis, and give the mental history which seems of more moment, and especially lay stress upon that part of the psychic history, the personality study and habit formation.

Our patient showed no unequal development. His power of observation was not very good, although the reproductive memory was fairly so. He had developed well and equally according to his opportunities.

His judgments were formed rather impulsively, the first one to be considered best, and most of his conclusions were arrived at with little deliberation. He was rather imaginative and resourceful as a boy, which continued in later business life. There is a distinct contrast between a certain amount of indefiniteness of purpose and lack of clearness of intention as shown in private affairs, and that of his general clearness and definiteness of purpose in business life. As a young man he planned for the day only, and did not look ahead. He was capable of mastering difficult situations, but experienced considerable trepidation and doubt until the actual work was begun.

He was always of a practical turn of mind, capable in handling tools, and lively and active as a boy. He had a very good understanding and appreciation of himself, was reliant, but always had a certain amount of internal misgivings as to just how to go at things. He was not conceited nor given to self admiration but rather the reverse. He was neverthless sincere, and disliked shams. He was rather inclined to remain by himself and not particularly sociable; not that he really didn't want to be, but it was too difficult for him to get *en rapport* with his social environment. He was not talkative with strangers and felt ill at ease in their presence. He got on better with boys, and was extremely diffident with girls. He was generous and over-trustful than otherwise. As a boy he was considered rather stubborn and self-willed, and was decidedly over-critical. His personality was of the open type, but not markedly so. He was rather over-conscientious in his school work, but was easily adaptable to the standards and moods of others. He was not suggestible nor imaginative and never had much self-assertiveness. His general mood was happy and even-tempered, but as a boy he had fits of rage, saw red, etc. He was mildly optimistic and not easily worried about the real daily tasks. He was considered quick-tempered, but this was more or less corrected in later youth. His temperament and general appearance followed the mother's type. His mother died when the patient was eight years old.

The patient's love affairs were frequent in early life, although he always felt ill at ease with the opposite sex. He was attracted to older women who seemed to resemble the mother-type. As he grew older this attraction was converted to almost the opposite physical type, and the age attraction steadily receded until now women several years his junior are most attractive. He had various love affairs, which were always broken off, the patient states, on reasonable grounds, but his explanations are unconvincing and vague.

He was natural in his manner with other boys in athletics and otherwise, but was rather particular and sensitive to bodily exposure. He has always been interested in his work, and is ambitious. He is fond of all outdoor sports. He prefers reading literature and classics to the lighter reading of the present time. He is not interested in religion nor is he superstitious or fanatical, and states that "these things do not concern him."

We have, therefore, as a summary from the patient's own story and corroborated by his sister, a young unmarried man rather strictly brought up as the term goes, who was always of a nervous temperament and especially lacked self-confidence. He was never sure of himself until actually on the job and in the mean-

time he was given to rigid self-examination and worry before each new task, whether studies at school, competitive games in athletics, or boy fights. The same feeling of inadequacy followed him in business life later. As he says, although events would prove that such feelings and thoughts were needless, they have continued to exist, even to this day, although he has much improved since the special treatment was undertaken.

An analysis of the sexual life showed that he had little sexual curiosity until about 13 years of age. The embryo formation of sex-hunger, however, showed itself at a very early age in his firm attachment to his mother, who died when the patient was but a child. The mother attachment was strong, as we shall see later.

He suffered forced kissing as a boy of 5, from his sister's older girl friends, which produced violent anger and a keen sense of outrage. At 7 or 8 years he was very repressed in manner and conduct toward the opposite sex lest he should be forced into the kissing embarrassment again. When 3 years old a little girl friend had bit him severely under the deception that she wished to kiss him. He was a moderate masturbator from the 13th to the 17th year and built up a lively sex fancy thereafter. In Java, under sexual restraint he had free "outlet sprees" of getting drunk. When sexual continence is maintained he has a good deal of anxiety and restlessness.

We have here, then, a hastily sketched and well-known type of neuropathic individual upon which psychopathic subsoil our tic torticollis developed.

The obvious cause of the tic would be the constitutional type of individual which has been briefly outlined plus the fact that the patient is an expert bookkeeper, accustomed to long hours of close desk application in which he is obliged to follow ledger accounts and price-lists spread out before him. In consulting these records a side-to-side movement of the head was almost the sole movement throughout the tedious day's work. The work was as strenuous as "making up railroad time-tables." The movement of the head to the left was several times more frequent than to the right, and quite of the type seen in the torticollis movement. The above explanation would be the popular and obvious origin, if not the real cause of the torticollis. However, we must go further back than this, to the patient's business experience in Java under a superior officer in the company, who was a very questionable commercial and moral character, and between whom there developed a keen antagonism. His superior took particular delight in complicating the otherwise harmonious business relations between the patient and the owners of the company. This man drank heavily and when he appeared at the office in an intoxicated state, as he frequently did, he was especially obnoxious and insulting to the patient, who thought he might be obliged to fight him or leave the firm's employ. Some of the patient's friends frequently told him he had better "look out," and "keep a sharp eye about him," and others suggested that someone might "stab him in the back," etc., etc. All these statements made an incisive psychic suggestion of obvious significance and intensified the patient's mental stress in his work, and he took added precaution that his superior might not "get anything on him" and thus cause his discharge. Added to the stress above detailed, extra work was put on him on account of the sickness of new arrivals in the office force to extend the firm's work in other parts of the island. Alcoholic indulgence then began to increase in our patient even more rapidly than ordinarily obtains in Europeans undertaking prolonged and arduous business in the tropics. Our patient was in Java several years. The keenness of mental and physical stress, alcoholism, and the peculiar character of the work detailed in the first explanation seemed at last sufficient to adequately explain the tic disorder. However, having reached this point we found we must still go deeper in the etiology for a more definite understanding, so we now enter upon the third investigation.

It will be remembered that the patient freely admitted that he was always of a nervous temperament, shy, diffident, and lacking in self-confidence, never sure of himself until actually on the job, always worried about his ability to do things whether at school, in athletic competitions, or in business, though to a less extent in the latter. Although he really had no cause to worry (he always did things well) yet with each new task the old feeling of inadequacy would return and plague him until the work was actually entered upon. It was found that on entering school at 5½ years of age he had a habit of stroking the left side of the occiput with the left hand. The stroking movement began with the fingers partially flexed and applied with slight pressure held motionless against the occiput, then the hand was allowed to slowly slip to the angle of the jaw, at which latter point of contact there was another short fixation of hand to jaw and firm pressure; then the hand was let fall. This rather common habit persisted throughout the whole of the patient's adolescent and adult life until about one year before the torticollis appeared. At this latter time the whole habit movement became for the first time a fully conscious one, and the patient made up his mind that the habit was purely mental, and "while it made no difference what the Malays and Chinese thought of his habit, it would seem mighty peculiar to civilized society, which he hoped soon to adopt again by returning home." Later information shows that his real motive for returning was to take up some of his old love affairs again and follow them to their natural conclusion. After considerable trials and self-conscious effort, he succeeded in breaking himself of raising his left hand to the head, but each time he checked the hand he noticed a slight instability, a sort of shaking tremor in the head, whose maximum of excursive movement was to the left. In the patient's words, "It seemed to be teasing for the petting movement of the left hand as of old."

Further inquiry revealed a still deeper and more satisfactory explanation.

In still more definite analysis it was found that the patient began the stroking of the head at the time of his entrance in school. As he had been taught at home he entered two classes in advance of boys of his age and was brought into association with those much older than himself and with whose play and mode of thinking he had little in common outside the recitation room. He therefore felt isolated from friendly associations and this increased his lack of confidence in himself so that the habit movement became doubly necessary and frequent as a protection from embarrassment and the trembling agitation of the daily recitations. Still further, it was found that during home instruction by an elder sister the patient used to recite to his sister standing and facing her, and during such recitations her right hand kept up a caressing movement which the patient afterward self-maintained. This sister's affectionate reassurance by stroking the patient's head always enabled him to gain confidence and learn easily.

Now for the real and final root of the habit movement out of which the torticollis grew: During infancy and until nearly three years of age, the patient remembers he was rocked to sleep in his mother's lap, and during her lullaby the mother used to keep up, as many mothers do, a light stroking of the patient's head. This was his favorite method of going to sleep.

*Summary.*—We have here a case of torticollis of the tic type which seems to have been precipitated by the character of the work above mentioned, but which has its essential origin in the order of its development from an infantile, pleasurable stroking movement started by the mother and continued until her death when the patient was eight years old, and which became a part of the education at home with the sisters and was self-participated in by the patient on entering school and continued through adolescent and adult life until brought into the conscious life, when the patient strove to break himself of the habit. Then the head developed a symbol or fragment mechanism and continued to perform its part of the act after the hand had ceased to cooperate in its part of the habit.

From a psychosynthetic point of view, these various trends or fragments in the psychic development of the tic would make, when chronologically arranged, a fairly understandable mosaic pattern of a ticeur, the neurotic center of which is largely conditioned by an abnormal sexual development. The case might then be stated as follows:

Our patient had an intensive love attachment to and for the mother, which is common enough, but in this case was kept up and cherished unconsciously, kept alive and intact by the mother's particular petting and caressing, and in consequence the boy was retarded and incomplete in opposite sex finding during early youth. The retardation was further increased by the forcible kissing episodes, which latter acts served as revivals of the psychic shock of being bitten instead of kissed at three years of age. Then there succeeded a rather late and prolonged period of masturbation aided and supplemented by the continuance of the autoerogenous habit movement of the head, which latter movement was made more intense when the inadequacies were manifest. In consequence of the above, the love affairs were superficial and indecisive in outcome, there was the migration to Java and the maladaptations there, the alcoholic indulgences, and the final attempt to break the habit of head stroking, and finally a pursuit of the love quest as shown in the patient's returning home for that purpose, and the final break into a real ticeur as shown in his mental torticollis when he tried to stop the habit movement.

Even a short summary of genesis of this single case of torticollis shows us the enormous pains one must take in unraveling the complicated mechanisms concerned in this form of psychoneurosis. Nor is the end yet. When the patient was given the full benefit of this analysis of the neurosis several months ago, there was an astonishing and immediate improvement. The old feeling of tension to hold the head steady largely disappeared.

Still the patient is not fully recovered. He still shows feelings of inadequacy and under difficult situations the torticollis returns, less completely and intensely it is true, but at times the tic is still there. Analysis is now in progress to root out the central core of inadequacy of feeling and will, etc., as far as possible.

I believe one is justified in saying that the central core of the habit movements is an autopleasurable act or acts based upon an inherent defect. When these autopleasurable acts are inhibited or modified they continue in tic movements in later life which still gratify an unsatisfied psyche. Inadequacy is partly analyzable in an over-ambition of the individual patient. A tendency latent or acquired to rise beyond the family stock level, a failure to reach this new goal, generates the need of some artificial help or stimulus, which is more or less the general problem of much of all our psychoneurotic and drug addicts. It will therefore be apparent to most that whichever school one follows, the old one that counted spasmodic or tic movements as an essential affection or expression of the will, of which the above case is a fair example, or the new analytic school, both schools arrive sooner or later at about the same spot, namely, that the essential defect in the tics is a neurotic constitution, the anlage. In other words, that tics occur in people essentially inadequate and inferior and that our efforts to correct the neurosis must be directed not alone to disclosure of the genesis of the movement but to a much more elaborate scheme of making the patient seek his own level in aim and capacity of life work. We can eradicate the tics just so far as one may gain the patient's confidence, cooperation, and his pliancy and will to readjust along these lines. I repeat, the tics and habit movements are compensation mechanisms or helps to overcome inadequate adaptation of the individual in his life work in the particular environment to which he is born.

The basis of the feelings of inadequacy is *doubt* and shares the same explanation in that it is a conflict between the primal love and hate instincts, and we have no right to charge the anlage too definitely with the burden ordinarily imposed upon it until we have sought to explain the inadequacy in its simplest terms. The conflict between the love and hate instinct is, of course, essentially infantile and during this period first one and then the other instinct strives to seek expression, and this engenders impediments in the developmental play of emotional and intellectual life. For instance, in our own patient, the essential constitution must have been greatly accentuated by the emotional trauma of forced kissing and the surprise of pain instead of affection in the three-year-old experience mentioned. The whole episode in itself engenders much thought in regard to the acts of kissing and biting in their relation to food and sex hunger and also their association to sadistic habits both in the child and in the sexual experiences of the adult life. The love and hate complex was singularly marked in our patient, who had fierce rages, saw red, trembled in anger, etc., but early learned to control the same in part, but even now, though very affectionate and peaceful by nature, he has periods of rages and a desire for destructive violence. All these factors concerning conflicts would be simply interesting and academic if it were not that they are the main sources of inadequacy expressed in weakening the will and incapacity for resolution. These defects are especially shown when love or pursuit of its ideals has been the issue. The love episodes were inconclusive, inconstant, and lacked definiteness and finality. Nor does such weakening of the will regarding love in its broadest sense remain long confined about the genetic goal, but easily spreads and ramifies throughout the whole life of the ticeur and forms no small part of the vacillating character in everyday life which such individuals usually show. It thus makes for much of the psychic deterioration which the French writers have particularly defined, but which they have naïvely said rarely amounts to intrinsic loss of mental capacity. Their view of the situation becomes much more understandable when we look at it more intently from our standpoint. The inadequacy of feeling, which is the outcome of the doubt instinct in action, corresponds to the inner irresolution which was formerly felt in the conflict of the old hate and love conflict now spread all over the psychic life, with renewed accessions of difficulties from time to time, and naturally turns with a greatly exalted value in the ticeur's movement, which was the original battleground of the first great conflict in infancy. In process of time the tic movement accumulates to itself still other obsessive movements and even thoughts, throughout the whole life of the individual, and these all become of immense importance and meaning to the individual personality. In many instances the tic movement only completely disappears when the original runways of feelings of hate are fully transmuted to paths of friendship, loyalty, etc. An incomplete transformation is, of course, the rule. One often sees ticeurs who think they have striven successfully in many instances to displace the original tic movement, but innumerable other small ones in

adjacent territories of movement have taken their place. It is quite obvious in such cases that their efforts at inhibition have caused the main issue of single tic to overflow, to become sidetracked, and in some instances the inhibition treatment pushes the patient into a pure obsessional neurosis or, worse still, the whole psyche may be engrossed, indicating that a deeper and more intangible mental disorder is in operation. The psychic contagion then becomes general.

Much more might be said here upon the successive orders of elaboration which the ticeur undergoes on his way to becoming a truly obsessive individual, and that his crude tic symbol may often be raised to the nth power of the grand obsessive neurosis, or, better, to a broad and deep habit of obsessive thinking. The natural history of this sort of pathological mind is still to be described. Perhaps I may be pardoned in reiterating that probably the greatest fault in the ticeur's disorder is not in the movement itself, but in the amount of isolation and banishment which the mental torticollis engenders within him. His conflict with his inadequacy, with his doubt, drives him away from reality and makes him lead a life apart. *He* thinks that it is due solely to the nonconventional movement in which he indulges that makes him shunned and stared at, and that the tic doesn't lend itself as a personal charm in ordinary social intercourse. His greatest fault is really due to his desire to concern himself with purely personal issues or unreality where the tension is less; where the goal is uncertain; where the speed in competition is not essential or not measurable, and where his individual efforts show up to less disadvantage than in the everyday world of facts and in competition with those free to run the race of life unimpeded. Further analysis of the ticeur's character and personality would lead us too far afield, as I am afraid these few random remarks already have done.

In conclusion I would say that the modern analysis of the tics and habit movements proves that the two are at bottom essentially alike in genesis, and that they are but a part of the large class of obsessive neuroses and should be handled and treated as such. Finally, I may say my case furnished an additional point of interest in racial psychology as regards the constitutional makeup of our neurotic, shown by the fact that our patient is one of a rather neurotic generation, which family is apparently the first one to appear in either paternal or maternal family stock. The father was a pure German type and the mother equally pure Irish; this, in the opinion of some eugenists, is not considered a good race crossing. I offer the statement for what it is worth.

## OPERATIONS FOR THE CORRECTION OF DEFORMITIES OF THE NOSE.*

By WILLIAM WESLEY CARTER, A.M., M.D.,

NEW YORK.

VISITING LARYNGOLOGIST TO GOUVERNOUR HOSPITAL, ASSISTANT SURGEON MANHATTAN EYE, EAR, AND THROAT HOSPITAL, CONSULTING LARYNGOLOGIST AND OTOLOGIST SOUTH SIDE HOSPITAL.

Gentlemen, I thank you most sincerely for the high compliment that you have paid me in asking me to appear before your excellent Society. Your President has requested me to present this subject in a practical way, and I am glad that he did, for I am quite certain that more is to be gained by a discussion of one's own clinical experiences and by demonstrating one's methods practically on the cadaver than by an academic presentation involving the rehearsal of all the literature upon the subject. I must say here that the literature upon bone transplantation is filled with fanciful opinions, many of which could not, in my opinion, be established by clinical experiment.

Fig. 1.—The Bridge-Splint.

For our practical purposes tonight nasal deformities may be divided into (1) Those without loss of tissue. (2) Those in which there has been more or less destruction of the bony and cartilaginous framework of the organ.

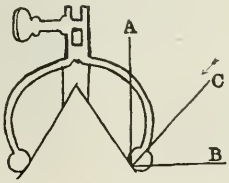

Fig. 2.—Showing the Mechanics of the Bridge-Splint.

In the first class the deformity is *congenital, acquired,* or due to *traumatism.* There is enough framework present but it is abnormally placed, thus producing the deformity. The majority of these cases are amenable to the bridge-splint operation, a procedure with which I am sure most of you are familiar, as I first described the operation several years ago. However, in discussing this subject it is necessary for me to refer to it in detail as in my opinion it is the most satisfactory method for correcting this class of cases.

The bridge-splint consists of a lightly constructed steel bridge, the two wings of which are hinged together in the middle, and the distance to which they can be separated is regulated by a thumbscrew. The edges of these wings are padded with rubber. The second part of the instrument con-

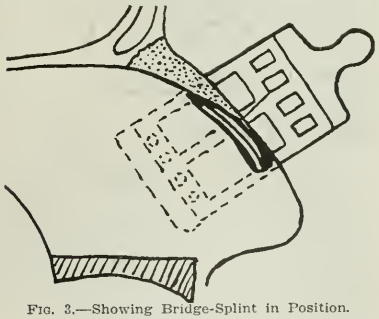

Fig. 3.—Showing Bridge-Splint in Position.

*Read before the Philadelphia Laryngological Society, October 21, 1913. (Practical demonstration on cadaver.)

sists of two small intranasal splints perforated by several small holes.

*Description of Operation.*—In describing the use of this instrument, we will assume either that we have a recent fracture, or, if it is an old deformity,

FIG. 4.

FIG. 5.—Showing correct position for transplanted bone.

that the framework of the nose has been thoroughly mobilized by suitable means; this involves the use of special instruments that I have devised for this purpose.

Silk sutures are first passed through holes in the intranasal splints and knotted. By means of a curved needle each suture is then passed from within

FIG. 6.—Rib-transplantation; specific deformity.

the nose through the roof fairly near the junction of the bony with the cartilaginous dorsum. The bridge is then placed over the nose and the correct amount of pressure applied to the base of the nasal arch by means of the thumb-screw adjustment. The sutures are then passed through corresponding holes in the bridge and sufficient tension applied to pull the nose up in to its proper position. The sutures are then tied together over the hinge of the bridge.

Though the apparatus is self-retaining and cannot be easily displaced, I have found that it is better to keep the patient in bed during the twelve days that it is necessary for him to wear it. This, however, is not necessary if the bridge is anchored to the forehead by means of an adhesive strap.

The instrument exerts its force along lines diametrically opposed to those of the force that produced the deformity. It tends to duplicate the forces employed by Nature in the development of the flattened nose of the infant into the normal adult organ.

I have found this instrument most useful in treating recent fractures, in correcting lateral displacements, depressed and irregular deformities.

FIG. 7.—Patient shown in Fig. 6 after operation.

This method has the great advantage of correcting the intranasal as well as the external deformity. In many cases it is necessary to do the submucous operation before attempting to correct the external deformity, but on several occasions, by making a

liberating incision through the septum above and below and then placing the bridge-splint in position, I have succeeded in straightening the septum and at the same time correcting the nasal deformity.

FIGS. 8-11.—Specific Destruction of Entire Nose. In this case bone from rib was first transplanted into the arm, and later flap containing bone was transplanted to face. Patient breathes through nose. Condition excellent two years after operation.

I have frequently used the bridge-splint in connection with the bone transplantation operation where there was need for additional support.

In cases where the nose is quite flat the septum is frequently too short to admit of the bridge being raised; in these cases I lengthen the septum by making a diagonal incision through it, beginning at the floor of one nostril and emerging at the roof of the other. Then when the bridge is raised the two segments of the septum can slide by each other to a certain extent, and the septum

FIG. 9.

is lengthened without causing a perforation.

In using this instrument it must be remembered that it is capable of exerting a tremendous force; we must be careful therefore to guard against too much pressure on the skin by the wings of the bridge. The edges of these wings should be well padded with additional layers of gauze, and each day the instrument should be loosened up by means of the thumb-screw and the skin where the instrument rests should be bathed with alcohol.

FIG. 10.

*Bone Transplantation.*—In the second class of cases, namely, those in which there is a deficiency in the bony framework, the transplantation of bone is indicated. The development of this method of correcting these deformities is due chiefly to my early recognition of the limitations of the bridge-splint operation.

Cases belonging to this class may be congenital, but they are more frequently due to atrophic rhinitis, to traumatism followed by secondary infections, and to syphilis.

The technique of the operation has been previously described, however, in order to present the subject clearly and to call your attention to certain

FIG. 11.

modifications I have made in the method of procedure, it is necessary for me to review the details of the operation:

First, it should be remembered in transplanting bone, that strict asepsis is absolutely essential; the

slightest transient infection means death of the bone graft and its subsequent absorption; therefore the greatest care should be exercised in every detail of the operation.

No syphilitic patient should be operated upon

Fig. 12.—Bone with periosteum—7 months after transplantation.

unless he is in a good physical condition and we are satisfied that his disease is in a quiescent state, the Wassermann test being negative.

Preparation of the Patient.—Several hours before the operation the skin over the nose, face, and right side of the chest is scrubbed with green soap, followed by alcohol. A wet dressing of bichloride 1-5000 is then applied. Just before the operation, both operative fields are painted with tincture of iodine, and the eyebrows are covered with collodion.

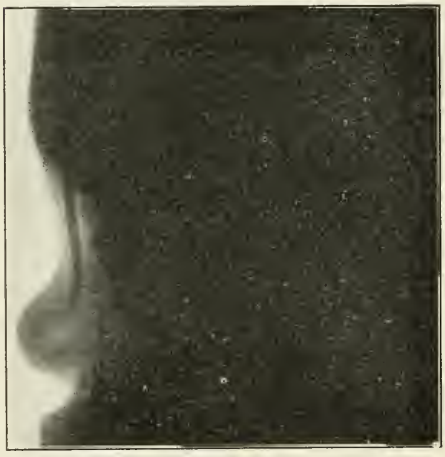

Fig. 13.—Bone transplanted with periosteum—15 months after operation. (Same case as Fig. 12.) Note development of canal in center of transplant.

After the operation begins no solution is used except sterilized physiological saline solution (Salt 9 gm., Sterile water 1,000 c.c.).

Technique of Operation.—A curvilinear incision, convexity downward, is made between the eyebrows; this incision extends down to the periosteum over the frontal bone. Lifting the flap up, a transverse incision is made through the periosteum and into the bone in order to favor osteogenesis at this point. This incision corresponds to a line connecting the two cornua of the semilunar incision, and is at a point just below the glabella. Above this incision the periosteum is elevated for about three-eighths of an inch. With the sharp elevator devised especially for this purpose, the skin and subcutaneous tissue is then elevated over the dorsum of the nose, and to an extent corresponding to the degree of deformity, over the sides of the nose and in some instances over the cheeks. If any of the nasal bone is left its periosteum should be elevated so that the bone graft, when it is introduced, will lie in close contact with the bone and its torn periosteum. The value of this is shown in the *x*-ray plates of one of my cases.

The nose having been prepared for the reception of the graft, we proceed to remove about two inches of the ninth rib, preserving the periosteum on the outer surface. This piece of rib is then split in its

Fig. 14.—Bone transplanted with periosteum—20 months after operation. (Same case as Figs. 12 and 13.) Note growth of bone and development of canal in center.

transverse diameter, the outer half is shaped to suit the deformity, and the cancellous tissue is scraped away, leaving only a thin layer of compact bone.

Without removing the blood, which by this time has accumulated in the wound in the nose, the bone graft is inserted nearly to the tip of the nose, and the upper end is carefully placed beneath the periosteum over the frontal bone. The semilunar flap is then brought down into its place, and the wound closed with horse-hair sutures. A collodion and gauze dressing is applied. The sutures may be removed on the fifth day, but great care must be exercised not to disturb in any way by manipulation the blood clot which has formed about the graft. The blood clot seems to favor osteogenesis.

When we get primary union there is no reaction of the tissues due to the presence of the bone graft; healing is usually complete in ten days.

If there are any signs of inflammation, even if the skin wound has healed promptly, the wound should be opened up. Unless the infection is quickly controlled the graft should be removed at once, for infection means death of the bone.

Value of the Periosteum.—Some widely divergent views in regard to the periosteum are held by those who have written upon this subject, but the prescribed limits of this paper prohibit my entering into a discussion of these views, and I must confine myself entirely to my own personal clinical observations and will demonstrate some of my results by means of photographs, casts, and skiagrams:

Fig. 15.—Bone transplanted without periosteum in contact only with nasal bones. Note growth at this point; 21 months after operation.

I have transplanted bone both with and without periosteum, and as my work in this field is, as far as I know, the first systematic effort made to introduce this method for correcting nasal deformities, my cases are of standing sufficiently long (4 years) to enable you to draw conclusions. Bone introduced into the soft parts, as into the nose, will give us a better idea of its individual characteristics than when it is used for filling in defects in the long bones, for in the latter situation it is being placed in its natural environment, where its own characteristics cannot but be confounded with those of neighboring tissues, namely, the periosteum and the bare ends of the injured bone.

All of my work has been upon the human subject, and while the advantages of the microscope have been necessarily precluded, the clinical course of the cases has been under constant observation, which is more to the point after all. My oldest case is of nearly four years standing and I have done in all twenty transplantations. The following observations are based upon this experience.

The autoplastic operation is preferable to any other. The rib is chosen for transplantation because it is conveniently located, it is suitable in size and shape and is abundantly supplied with nutrient foramina. Further, the removal of a piece causes the patient little or no inconvenience, and it is soon reproduced.

The results may be tabulated under the following heads:

(1) Cases where bone uncovered by periosteum has been anchored under the periosteum over the nasofrontal process. Primary union having been obtained, the bone is firmly united to the frontal bone, the graft appears larger at this point, and the growth of bone has extended down the graft for some distance. Also in those cases where the graft lay in intimate contact with the nasal bones, these having been denuded of periosteum, there is also a growth of bone at the point of contact. The portions of the graft furthest from the bone and periosteum contacts remain about the same in size as when the bone was transplanted.

In this class of cases the bone graft seems to have been acting in an osteoconductive and osteogenetic capacity. The transplant certainly has taken on active growth at points where it comes in contact with the living, periosteum-covered bone.

Running down the center of the transplant in these cases and in all of my cases of long standing there is seen a thin line of rarefaction. This I believe is a nutrient or medullary canal in the process of development. If the original graft was being absorbed it would seem that this would begin on the outside of the graft and not in its center.

(2) Bone grafts either covered by periosteum or bare, but accidentally separated from the living, periosteum-covered bone.

The graft appears to be osteoinductive and very likely osteogenetic. In one case now under observation the transplant is considerably larger than when it was introduced, the operation having been done two years and five months ago.

(3) Infected cases, where the transplant had to be removed. In two cases where the infection was controlled without the removal of the bone, this was gradually absorbed, and connective tissue deposited in its place. In these two cases the deformity is not as bad as it was originally.

(4) Cases in which periosteum-covered bone was successfully implanted (see Figs. 12, 13 and 14), the upper end being in contact with the frontal bone and covered by its periosteum. Here there has seemingly been no disturbance whatever in the vital processes of the transplant, for it has become firmly attached to the frontal bone and has increased in size. But in this as in other cases there is the same rarefied area running down the center of the transplant.

Now to recapitulate: (1) Bone transplants, whether covered with periosteum or not, when free in the tissues and having no connection with living, periosteum-covered bone, probably act in a bone inductive capacity, the osteoblasts contained in the transplant taking part in the process. It may be

Fig. 16.—Same as Fig. 15, two years and four months after operation.

that the original bone in these cases is absorbed.

(2) Bone transplants uncovered by periosteum, when connected with live, periosteum-covered bone, are osteoconductive and osteogenetic.

Fig. 17.—Bone transplanted without periosteum 1 year and 5 months after operation. Note growth of transplant where there are contacts with the living periosteum-covered bone.

(3) Periosteum-covered transplants are osteogenetic when they are in contact with live, periosteum-covered bone.

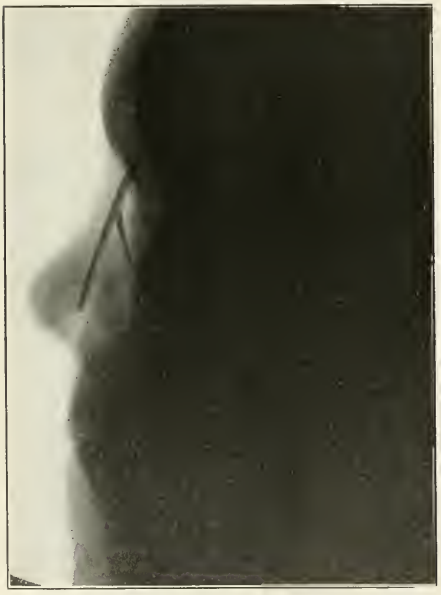

Fig. 18.—Showing dorsal fragment of transplanted bone supported by a pier formed by two other fragments.

I cannot, in view of the clinical evidence before me, subscribe to Macewen's proposition that the periosteum acts only as a limiting membrane and has no osteogenetic function. In my cases the influence of the periosteum as an osteogenetic factor is pronounced, and its absence is equally marked. This osteogenetic function is more marked the younger the patient. At the same time I will say that I have not found the periosteum necessary in correcting nasal deformities, but the transplants are in a more flourishing condition in those cases where I have preserved this membrane.

In conclusion I will say that I have found very satisfactory indeed this method of correcting a class of nasal deformities for which little or nothing has hitherto been done. And the excellent condition in which I now find some of my oldest cases has established my confidence in the permanency of the results obtained.

69 West Fiftieth Street.

## HYPOPHYSEAL DISEASE AS RELATED TO DIABETES INSIPIDUS;

### WITH REPORT OF TWO CASES.

By David B. Jewett, M.D.,

Rochester, N. Y.

Diabetes Insipidus, the name applied to a long continued polyuria, has always been a most indefinite syndrome in its etiology, pathology, and treatment. The pathological findings at autopsy have been obviously secondary in character and the long list of remedial agents advanced, as always, bear witness to their comparative uselessness. The researches of Meyer pointed out some facts regarding the excretion of sodium chloride and the permeability of the kidney to secrete urine of a certain specific gravity, but the attempt to apply this work clinically to two of the cases reported below, resulted in comparative failure. Cushing, in his monograph, called attention to the frequency of polyuria in pituitary disease and it is apparent that the entire subject of diabetes insipidus must be recast, and that hypophyseal disturbance will be found the causal factor in many cases.

Experimentally, Schaffer found that the administration of posterior lobe extract produced polyuria and then Cushing and his coworkers in a long series of animal experimentation showed that posterior lobe manipulation caused diuresis and sometimes an extreme long-continued polyuria; that posterior lobe implants caused a polyuria that stopped on removal of implants; that clean-cut posterior lobe removal produced polyuria with greatest certainty. It was also demonstrated that diuresis could be produced by stimulation of the autonomic system of nerves; the nerve impulses of which pass from the medulla through the cord to the upper three thoracic nerves and thence by way of the cervical sympathetics to the hypophysis. This fact is the probable explanation of the so-called neurogenic or hysterical polyurias. The above investigators, in addition, report what seems to me a most significant fact that the most enduring polyurias occur when the hypophyseal stalk has been cut or obstructed, leaving the gland intact.

Clinically, it is observed that a large percentage of the cases of diabetes insipidus have shown basal brain lesions, like a gummatous meningitis in the middle fossa; that bitemporal hemianopsia and primary optic nerve atrophy have been frequent findings. The following cases reported by Reubens in a recent article are of interest: Kohler found affections of the infundibulum in 7 of his 22 cases of diabetes insipidus; Oppenheim in 36 patients

with basilar luetic meningitis observed polyuria in 12; Kruse in 34 cases of bitemporal hemianopsia observed diabetes insipidus in 7 cases; Oppenheim in 2 cerebral cases with double bitemporal hemianopsia and diabetes insipidus, found on autopsy a gummatous meningitis in the chiasmal region; Hagenback (1882) found a tubercle of the infundibulum in a girl who had thirst and polyuria; Rosenhaupt (1903) reported a case of diabetes insipidus in which there was a metastatic carcinoma of the hypophysis, and Simmond reported a case of gunshot wound of the hypophyseal neighborhood with diabetes insipidus following.

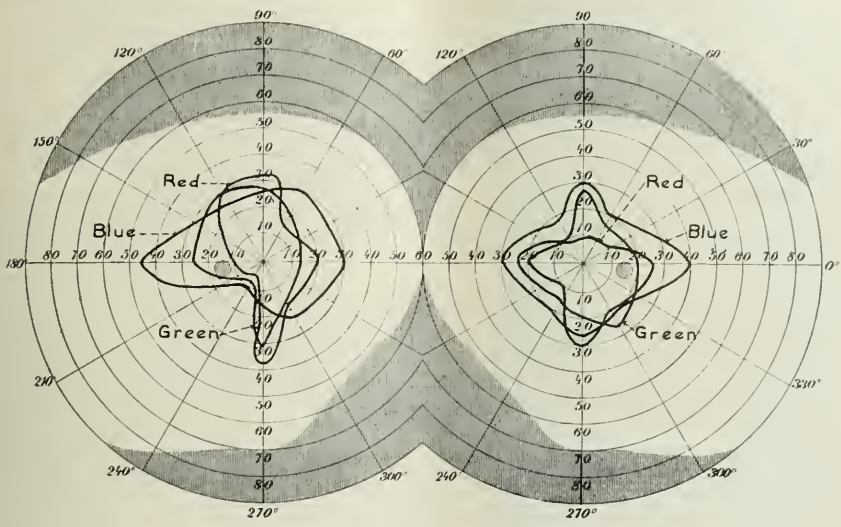

FIG. 1.—Visual fields in Case I. Note the constriction and the color interlacing

FIG. 2.—Radiogram of a skull in Case I, showing a very small sella (dotted outline) with heavy bone contour. (Radiologist, E. B. Cook.)

Cushing, in a paper, "Concerning Diabetes Insipidus and Polyurias of Hypophyseal Disease," cites E. Franks' patient, who received a bullet wound of the pituitary fossa with the subsequent development of a diabetes insipidus, adiposity, and other symptoms of hypopituitarism. He also quotes Simmonds of Hamburg, whose patient, after removal of a cancer of the breast, developed a severe polyuria and who found by autopsy a metastatic nodule that involved the posterior lobe and the hypophyseal stalk; the pars intermedia and the inferior lobe remaining free, and Simmonds thinks that the pars intermedia was activated to hyperfunction by the destructive process in the posterior lobe. Cushing relates a similar case with a severe polyuria in which autopsy revealed a metastatic growth of the thickened stalk of the pituitary body. A most interesting clinical case is cited by Cushing of a patient who developed an extreme polyuria as a result of a sellar decompression, a condition similar to that following hypophyseal manipulation in animals. Many authors have reported diabetes insipidus following cranial injuries which may occur when the pituitary fossa is not involved because the gland is the seat of extravasation.

The recital of this experimental and pathological evidence certainly links disturbances of the pituitary gland closely with the subject of dyspituitarism found in the textbooks under the discussion of diabetes insipidus. For example, Pepper in his "System of Medicine" (1886) gives the following symptoms as occurring: "Dryness of skin frequently noted which is said to mark the difference between polyuria and polydipsia, in the former the skin being dry, and in the latter moist, severe headache is of importance." Gerhardt, in "Modern Clinical Medicine," 1906, gives as symptoms of diabetes insipidus: "No sweating even in summer heat; temperature conspicuously low; enormously increased body weight; epilepsy and psychical disturbances often associated; some cases with emaciation and marasmus usually with mental changes."

Fenwick, in "Twentieth Century Practice of Medicine," says: "The temper is capricious, the bodily and physical strength impaired, the sexual powers are weakened, and the skin is hot and dry." Boyd, in his "Encyclopedia Medica," Vol. II, 1889, says:

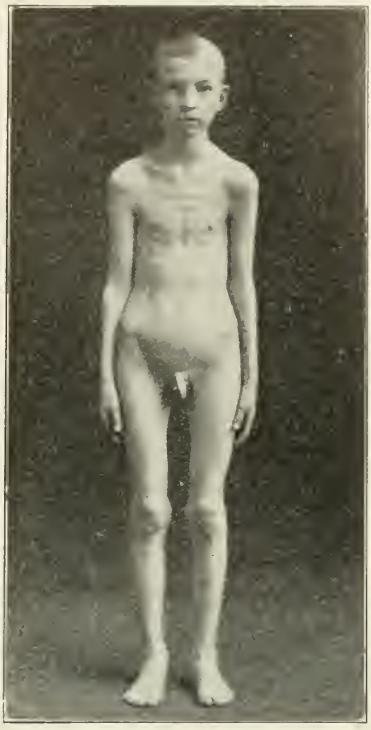

Fig. 3.—Case I; photograph of patient taken after marked improvement had taken place.

"Temperature is subnormal, the skin is dry, the nervous system is disturbed, amblyopia is common, and the sexual powers are enfeebled." There is a familiar sound about these symptoms to one who has read Cushing's cases of pituitary disease.

In 100 examples of hypophyseal disease studied by Cushing, in six a polyuria of sufficient severity existed to justify the diagnosis of diabetes insipidus. The following cases to be reported were considered and diagnosed diabetes insipidus by the author, and several others until they were studied from the point of view of pituitary disturbance.

Case I.—L. M., age 12 years. Dyspituitarism, with symptoms of diabetes insipidus, hypophyseal insufficiency and emaciation. Improvement followed anterior lobe feeding. There was nothing noteworthy in the family history or personal history except that he had severe electric burns of hands about 3 years ago. Present illness: In September, 1911, his mother first noticed increased and frequent urination. This condition continued, and in January, 1912, the patient had a voracious appetite, and is said to have gained considerably in weight. He also had some sleepiness and headaches at this time. In January, 1913, Dr. Doane referred him to the writer with the diagnosis of diabetes insipidus. He was put in the hospital for treatment. While there he had a subnormal temperature (average 97° F.), and voided from 8 to 9 quarts of urine a day. While in the hospital the urine decreased to 5 to 6 quarts a day. His further course was uneventful to January, 1913, when he became very somnolent, hardly answered questions, had a staggering gait, and developed some edema of the forehead. (Cushing has noted a similar condition in animals.) In March, 1913, the results of an examination were as follows: A fairly well nourished boy, weight 83 lbs., normal skeletal development. Heart and lungs normal and abdomen negative. Urine, 5 to 6 quarts in 24 hours. Sp. G. 1001 to 1003, very faint trace of albumin, no cellular elements. Systolic blood pressure, 110. Very drowsy and hardly answered questions, and did not hold head erect; shuffling gait; severe frontal headaches. Vomiting present. The skin was dry, the sexual organs were undeveloped. He complained of feeling cold. There was no hair in the axilla or on the abdomen and pubis, though there was abundant hair on the head. The crescents on the finger nails did not show. The cranial *x*-ray examination showed a very small sella with heavy bony contour, measuring 4 by 4 millimeters. The optic nerve showed no abnormality, but Dr. Doane reported some restriction of the visual fields.

Subsequent History: Pituitary feeding was commenced (2 to 5 grains) of the whole gland substance, at first with marked improvement, but later was discontinued because of vomiting and increased temperature, which were thought to be due to the gland feeding. In July, 1913, his condition was much more serious; he could not stand alone, was alternately very drowsy or very noisy, had lost weight (71 lbs.), become quite emaciated, and a paresis of the left arm, leg, and face appeared. At this date he had a convulsion which may have been an uncinate seizure, but this is doubtful. Because of the increasing sleepiness, headaches, vomiting, and paresis of one side, thinking some surgical procedure must be performed for the relief of the increased intracranial pressure, I sent him to Dr. Harvey Cushing's service at the Peter Bent Brigham Hospital, where a subtemporal decompression was performed in August. Later the whole gland feeding was given for two to three weeks without marked results, and then Dr. Cushing prescribed anterior lobe alone, which was followed by marked mental and physical benefit. On November 1 there were present slight headaches (with some bulging of the region of the decompression), slight photophobia, the weight was 64 pounds, and four quarts of urine were voided in 24 hours. Though far from a healthy boy there was a wonderful improvement over his past condition.

General Considerations: The headaches, dry skin, sexual infantilism, polyuria, polydipsia, and the small bony sella makes one sure of a disturbance of pituitary function. It is also probable that there is a glandular insufficiency and the result of

Fig. 4.—Radiogram of the skull in Case II, showing a sella with double contour. (Radiologist, L. J. Sanders.)

feeding suggests that the main trouble is in the anterior lobe. The polyuria is not greatly improved, as many times during the summer the total quantity of urine was not above four quarts. In posterior-lobe insufficiency obesity is the com-

mon finding and the presence of marked emaciation in this case probably is similar to the result of removing the anterior lobe in animals (cachexia hypophseopriva). The experiments of Lewis and Miller of feeding anterior lobe to animals without marked effect show that such feeding does not coincide with clinical results, and as they indicate such feeding "can scarcely be considered as analagous to the continuous secretion occurring in actual life." The conclusion of these authors that adiposity is "most probably due to the hyposecretion of the anterior lobe" is not substantiated by this case and by its marked improvement following anterior lobe feeding.

Case II.—An adult presenting symptoms of hypopituitarism with a menorrhea, obesity, and increased carbohydrate tolerance—having a very marked diabetes insipidus as the principal symptom. Mrs. M., aged 46 years. Her father and mother died of apoplexy, remainder of family well. One brother inclined to obesity, another brother very slender. She had always been well in her earlier life up to the age of 20 when she occurs when there has been considerable distention. She has headaches at present, but these are not to be compared with those of 20 years ago. Carbohydrate tolerance tested with 200 grams of levulose with no glycosuria resulting.

General Considerations: This patient presents amenorrhea, obesity, increased carbohydrate tolerance, somnolence, polyuria, and polydipsia, restricted visual fields, headache, and a sella that suggests a previous distention.

The first of these cases suggests anterior lobe insufficiency, while the second has the symptoms (obesity, increased carbohydrate tolerance, etc.) usually associated with posterior lobe insufficiency. A severe continued polyuria is common to both and at present no plausible explanation of this symptom is possible except that it is a frequent finding in dyspituitarism. Clinically, polyuria is associated with cases of deficient or diminished activity of the gland while experimentally, feeding posterior lobe extract produces diuresis; implants produce polyuria that ceases on removal of the implant. To

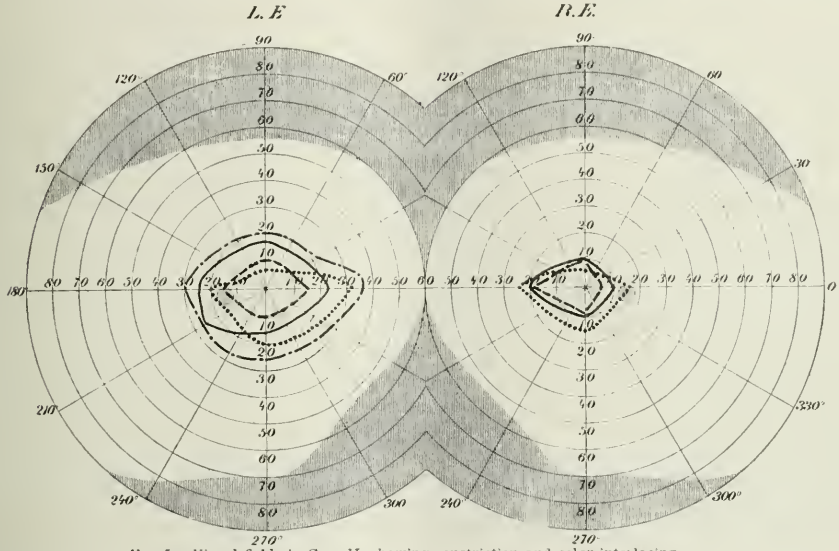

Fig. 5.—Visual fields in Case II, showing constriction and color interlacing.

noticed that the amount of urine began to be excessive and was followed by a period of 2 years, during which time there was no menstrual flow. At 23 years of age she married, and 3 years later a child was born, following which she began to gain weight rapidly. Her weight before marriage was 125 pounds, and within a year after the birth of her boy she weighed 200 pounds. Since that time she has continued to gain a little weight, her weight now being 240 pounds. Fifteen years ago she had very frequent and severe headaches. Seventeen years ago she had a "phantom pregnancy" with no menstrual periods for one year. Since then she has menstruated three to six times a year. She has a polyuria of 14 to 16 quarts a day, and has been told by many doctors that she has diabetes insipidus, but after trying many treatments without result she has abandoned all treatment. She is very drowsy, "can sleep at any time," there is polydipsia and polyuria, the skin is dry, and there is no hair on the body except very slightly on the vulva. She is sensitive to cold. Physical examination reveals no thoracic or abdominal abnormalities. Hemoglobin, 90 per cent.; smear, normal. Systolic blood pressure, 110. The ophthalmoscopic examination is negative, but the fields are much constricted with the interlacing of color fields (Barber). *X*-ray examination shows a sella measuring 9 mm. anteroposteriorly in depth, with a double contour that often add further to the confusion Cushing has shown that clean-cut posterior lobe removals produce diuresis and that hypophyseal manipulation often induces polyuria. No adequate explanation of its occurrence has as yet been found. We may safely say that polyuria is frequently a symptom of dyspituitarism, but we are ignorant as to the exact disturbance of glandular function responsible for its occurrence; that the result of Case I suggests that emaciation may be a symptom of anterior lobe insufficiency and that the experimental and clinical evidence indicates that many if not all cases of so-called diabetes insipidus are in reality cases of dyspituitarism.

**The Contagiousness of Meningitis.**—C. Dapter concludes from his observations that meningococcic meningitis is a contagious disease, being preceded, accompanied, and followed by a meningococcus rhinopharyngitis. The latter is the real contagious or epidemic disease, which may or may not be accompanied by meningitis.—*La Press Médicale.*

# A CASE OF SCLERODERMA.

By A. J. GILMOUR, M.D., Ph.B.,

NEW YORK.

CONSULTING DERMATOLOGIST, MANHATTAN STATE HOSPITAL; ASSISTING ATTENDING DERMATOLOGIST, NEW YORK CITY CHILDREN'S HOSPITAL AND SCHOOLS.

THE following case report, dated October 7, 1913, is placed on record:

J. N., male, age 58, white; Nativity, Ireland; married. Family history: negative. Personal history: negative. Present history: Patient was in perfect health before and on Election Day, 1912. On that evening about 10 P.M. while watching the returns "hands and feet felt on fire." The patient took his hands from his pockets, removed his gloves, and noticed his hands were red and spotted with white patches. Two or three days later the hands had regained their usual appearance and remained so for about two or three weeks.

The patient then noticed the index and middle fingers of the right hand and the index middle and ring fingers of the left hand were gradually becoming affected with a stinging pain. This pain lasted two or three weeks during which time these fingers were gradually becoming a black color. Their discoloration increased for two or three months with a concomitant hardening and thickening of the skin. This skin loosened somewhat from the fingers and made a cast surrounding them. "It resembled celluloid." The edge of this blackened and hardened skin kept gradually scaling for the next month. The fingers were apparently well, and their normal function was preserved. The only abnormality complained of by the patient was a tenderness when the fingers were struck. This apparently normal condition after the fingers cleared up lasted about two weeks. The hands and feet gradually developed an edematous swelling during the next two months, after which a redness slowly appeared on the posterior aspect of the joints of the hands and feet. The patient has lost 29 pounds during the last ten months. His appetite has gradually failed so that at the present time there is little desire for food. The patient has been hoarse for the past five months, and for the last three months he has had a sharp pain of short duration whenever he swallowed solid food, liquid food or even his saliva. "It catches on both sides of the larynx," but only for a second. This condition has gradually become worse.

Physical examination: The larynx shows the cords on their outer edge to be red and thickened, giving the appearance of a band. The involvement is as follows: The skin of the face is thickened and has a mask-like appearance. It is smooth and shiny with an obliteration of the wrinkles. This is especially well shown at the location of the outer ends of the crow's feet about the eyes. The extent of the face involved is a symmetrical area extending 1½ inches below and to the outer side of the eyes. The process in this location has been going on for three months. Both ears are red. They burn when the patient sleeps on them

The entire circumference of the chest gives a slight intimation of thickening, but thickening is distinctly seen on the front of the chest above a line connecting the axillary folds. This area is smooth, thickened and has a pinkish color. Small dilated capillaries are scattered over this area. The circumference of the neck is slightly involved, but with little apparent thickening, and with no change of color. The parts most involved are the limbs, especially the forearms and hands; these are markedly atrophic, the other parts to a lesser

degree. These are symmetrically involved. The tips of the elbows show a slight redness, and thickening. The entire back of the hands is brawny and thickened. There is an especially bright red streak ½ inch broad that runs up the radiodorsal surfaces of the forearms for 5 inches, and an even more acutely red streak of the same width runs up the posterior ulner sides for 2 inches. The fingers are the most involved, and are quite incapacitated. They are smooth, brawny, thickened, contracted and held one-quarter closed, giving the appearance of a claw. They are so stiffened that the patient can move them only at the metacarpophalyngeal joints, and there but slightly. The thumbs are held quite straight with a very marked limitation of motion. The patient dresses with great difficulty. Passively, the fingers can be a little extended, and this with a crackling sensation. The patient on active motion of the neck at times notices the same crackling sensation. The fingers have been bent for the past four months (see illustrations). There is a slight reddish pink color over the dorsal surface of all the finger joints. The knees over the extensor surface show a slight redness but no marked thickening. Both feet are smooth and thick, the same condition extending 2 inches above the ankle joint. The color is a bluish red. There is but slight limitation of motion in the joints of the feet and ankles, but enough to make the patient walk lame. Atrophic changes are well marked in the hands, feet, and to a less extent in the face. The skin is dry, smooth, thinned and stretched over the underlying subcutaneous tissues. Examination of the urine is negative. The Wassermann reaction is negative.

Treatment: The patient has been under observation since July 17, 1913. He has continuously taken thyroid extract (protonuclein of Beebee, gr. v.) three times a day after meals. My colleague, Dr. Lange, who has followed the case, maintains there has been some softening of the skin under this treatment.

November 26, 1913. Since the original report of this case the patient died.

Ten days before his death the patient was troubled with his breathing and again had the same symptoms two or three days before his death. He complained of a shortness of breath as if he had hurried upstairs. On November 26, 1913, the patient was at work as usual.

He returned to his home, ate a good supper, and retired at 9 P.M. At midnight the patient walked into his son's room and said I want to be fanned. The breathing was quick and short. There was a wheezing as if breathing were a great effort. He said he could not breathe. The doctor who immediately responded to the call told me it was at once evident the patient would die, that there was a spasmodic contraction of all the chest muscles. He believed the cause of death was a tightening of the chest brought about by the scleroderma.

The doctor in attendance talked over the case with a well-known medical man who had previously seen the patient and the diagnosis of pulmonary edema was agreed upon for the death certificate. The heart beat was heard with the phonedoscope five minutes after the respiration ceased. The patient died at 12.30 A.M., about one-half hour after the begininng of his attack.

## THE DRUG-HABIT MENACE IN THE SOUTH.

By EDWARD HUNTINGTON WILLIAMS, M.D.,

MONTCLAIR, N. J.

FORMERLY OF THE NEW YORK STATE HOSPITAL SERVICE.

From the evidence offered by the State Hospital records it appears that there is a far higher percentage of drug habitués per capita in the South than in most of the Northern States. Moreover, in the Southern States drug habituation seems to be increasing rapidly in certain localities, whereas in many of the Northern States there appears to be an actual decline.

In 1912 the proportion of cases of drug psychoses admitted to the hospitals for the insane in New York State was only 1 to 386 of all other forms of aberration. During this same period the proportion in Georgia was 1 to 42; in North Carolina (Raleigh), 1 to 84; in the Eastern Hospital, Tenn., 1 to 74; in the Mississippi State Hospital (1911), 1 to 46; and in the Eastern Mississippi State Hospital, 1 to 23, during the same period. In other words the proportion of drug-takers admitted to the insane hospitals in the South was from five to fifteen times greater than in New York State.

One naturally assumes that the large negro population of the South is responsible for this striking difference in conditions. But this assumption is not sustained by the hospital records, at least as regards actual insanity. Thus in the Georgia State Hospital, where the proportion of negro patients to white is about three to four, there were only four cases of drug intoxication among the negroes in 1911, while the number of white patients was twenty-six. In 1912 the number of cases of this form of psychosis had risen to twenty-seven among the whites, while there were no cases among the negroes admitted. And a similar, although less striking, discrepancy is found in other hospitals where white and colored patients are admitted.

Apparently, then, the difference in race does not explain the relative difference in numbers of this form of psychosis. And yet there seems to be no question that drug-taking is practiced among the negroes to a far greater extent than among the white population, or that it has increased with alarming rapidity during the last four or five years.

The insane hospital records show that morphine is responsible for most of the committed cases of drug psychosis, while cocaine plays an insignificant and entirely subordinate part. Yet cocaine is the drug usually taken by the negro drug-taker—is, indeed, becoming a veritable curse to the colored race in certain regions. And when we turn from the hospital records to the records of the jails, work-houses, and prisons, we find ample explanation for the negro drug-taker's absence from the hospitals. He isn't in the hospital because he has stopped in the penal half-way house. In some places his numbers tax the capacity of these institutions.

Moreover, the authorities admit their inability to prevent the negro from getting his supply of cocaine, or even to determine where he gets it in most instances. They admit freely that there is an enormous underground traffic in the drug, and that any negro who can scrape together a few cents can get a supply whenever he wishes it. And of course this traffic is not confined to the negroes, but extends to the "poor whites" who occupy about the same social and intellectual plane.

In many of the towns and cities the bootblacks and newsboys act as common vendors—retailers, so to speak, who loyally refuse to reveal the sources of their supply even under most extreme pressure. They sell the commodity in the form of "snuff," a vile concoction composed of a small proportion of cocaine mixed with some white powder (such as Epsom salts) to give it bulk. "Ten cents a sniff" is the usual price for an individual "dose." But the more affluent purchaser who can raise the sum of twenty-five cents may get a good day's supply for that price, which is dispensed in small paper pill-boxes.

Once the negro has reached the stage of being a "dope taker"—and a very few experimental sniffs of the drug make him an habitué—he is a constant menace to his community until he is eliminated For his whole nature is changed for the worse by the habit. Sexual desires are increased and perverted, peaceful negroes become quarrelsome, and timid negroes develop a degree of "Dutch courage" that is sometimes almost incredible. A large proportion of the wholesale killings in the South during recent years have been the direct result of cocaine, and frequently the perpetrators of these crimes have been hitherto inoffensive, law-abiding negroes Moreover, the negro who has once formed the habit, seems absolutely beyond redemption. Imprisonment "cures" him temporarily; but when released he returns to the drug almost inevitably.

But perhaps the most interesting feature of the effects of cocainism, at least from a medical standpoint, is the fact that the drug renders the user immune to *shock* to an astonishing degree—a condition adumbrated by Crile in his classic experiments of 1897.* In the language of the police officer, "the cocaine nigger is sure hard to kill"—a fact that has been demonstrated so often that many of these officers in the South have increased the caliber of their guns for the express purpose of "stopping" the cocaine fiend when he runs amuck.

An experience of the Chief of Police, D. K. Lyerly, of Asheville, N. C., is illustrative. In attempting to arrest a hitherto peaceful negro who had become crazed by cocaine, Lyerly was forced to grapple with the man, who slashed him viciously with a long knife. In self-defence the officed drew his revolver, placed the muzzle over the negro's heart, and fired—"for I knew I had to kill him quick," the chief explained.

The revolver he used, be it understood, was not the short-cartridge, pocket weapon caried by most Northern policeman, but a heavy army model of .32-20 caliber—a cartridge which Lieut. Townsend Whelen, U. S. A., declares will kill any game in America. And yet this bullet did not even stagger the crazed negro, and neither did a second bullet

*This resistance to shock seems to verify clinically Dr. Crile's experimental observations made in 1897. In his "Cartwright Prize Essay for 1897" he summarizes one phase of his exhaustive investigations as follows: "In a series of experiments on cocaine administered hypodermically to prevent splanchnic shock, there is strong evidence as to its efficiency."

which pierced the biceps muscle and entered the thorax. So that the officer had finally to "finish the man with his club." The following day Mr. Lyerly exchanged his .32-20 for a .38 caliber army model, the weapon carried by the men of our army and navy. And a similar exchange has been made by many of the officers in the South who have had experience with the homicidal negro, both before and since the days of cocaine-taking.

Needless to say this immunity to shock, together with the fearlessness, hallucinations, and homicidal tendencies that cocaine engenders, makes the "fiend" an object of special dread. But the drug has still another effect that makes him peculiarly dangerous. Unlike the effects of whisky, cocaine seems to put the muscular and nervous system of the user temporarily in a state of tense stability, so as to improve, rather than interfere with, his marksmanship.

It seems to be an established fact that the abuse of ardent spirits interferes with good shooting. But such an example as that of the cocaine-crazed negro in Asheville who killed five men dead in their tracks with one shot for each, shooting at long range in some instances, demonstrates that cocaine does not impair eyesight or muscular coordination. I doubt if this feat in markmanship—actually killing, not merely wounding, five men with five shots—has been equalled in modern times. And undoubtedly the negro could not have accomplished it under the stimulus of any other known drug.

We should not, of course, draw too definite general conclusions from a single example. But there have been so many other instances in which the cocainized negro has exhibited deadly accuracy in shooting, such as the recent slaughter of nine persons at Harriston, Miss., and the shootings in Memphis, that there is no escaping the conclusion that cocaine, besides making the habitué homicidal, adds to his ability to carry out the homicidal intent.

The habit of cocaine-taking, while not entirely a novelty in the South, has developed into a veritable epidemic of alarming proportions only within the last few years. I was told by physicians and officers in many places that five years ago the "cocaine fiend" was practically unknown in their communities. A year or two later he had become a menace; and since that time the number of cocaine-takers has trebled and quadrupled in many places.

What is the cause of this sudden increase? And why does the negro and the poor white now take this hitherto little used, although long-known, stimulant?

For the purpose of trying to find a satisfactory answer to these questions, as well as to determine whether the drug-habits in the Southern States are really as common as the printed records indicate, I have recently taken an extended journey through certain regions of the South where these conditions seem to flourish. In this quest I visited State hospitals, county hospitals, jails, workhouses, and prisons, and interrogated patients, prisoners, physicians, and officers.

Everywhere I found evidence that the cocaine habit is increasing: there was not a single dissenting opinion. And since this universal belief is confirmed by police and hospital records, it may be accepted as a definitely established fact. I found also a unanimity of opinion, among those competent and in a position to judge, as to the cause of this appalling condition. A prisoner put the thing in a nutshell in answering my question as to why he began taking cocaine, when he said: "'Cause I couldn't git nothin' else, Boss."

Ever since the emancipation of the slaves the South has been confronted by a problem that does not exist in the North. This problem is the control of the negro—particularly the low-class negro. Since numerically the colored people represent from 30 to 60 per cent. of the population in these States (no Northern State has even 5 per cent.) it is evident that any race-problem that concerns the negro in the South is one of first magnitude.

Of course the colored man, like his white neighbors everywhere, is likely to commit lawless acts when unler the influence of strong liquors; and because of his inferior mental organization, sometimes perpetrates the most revolting crimes when intoxicated. And since the control of the sober negro offers a sufficiently difficult problem in communities where every other man is colored, it is naturally the earnest desire of the authorities to eliminate the added menace of the drunken negro. Moreover, since most of the Southern negroes are poor, illiterate, and shiftless, the controlling white men thought it would be a blessing to the colored man himself, as well as to the community at large, to put whisky out of his reach.

The simplest way to do this, it seemed, would be through the agency of prohibitive legislation. And so Georgia, Mississippi, North Carolina, Tennessee, South Carolina, and West Virginia, passed State-wide laws intended to abolish the saloon. These laws, of course, do not prevent the white man, or the well-to-do negro, from getting what liquor they wish, and, when they wish it, through legitimate channels. It is considerable trouble, to be sure, to write, send money, and receive packages by express; but the white men were ready to sacrifice this inconvenience if by doing so they could keep strong drink away from the shiftless and dangerous negro.

The task did not seem impossible, since active police work would close the saloons and dives. And by doing this they would (theoretically, at least) make it practically impossible for at least 25 per cent. of the total population to obtain whisky. For the number of negroes, and poor whites, who have sufficient intelligence, education, and money to send away for their liquor is extremely limited. And so these States entered upon a hoped-for Utopian period by abolishing the saloons—"the blessing of prohibitive legislation," as some enthusiasts called it. But the "blessing" was not to prove an unmixed one by any means, as subsequent events have proved.

For the negro, and the white man, quickly discovered that there were other substances besides alcohol that produced pleasant intoxicant effects—substances that are measured in fractions of grains instead of fractions of gallons. Morphine and cocaine offered the most alluring attractions, although there were certain soda-fountain beverages, and drug-store nostrums, that could be requisitioned in a pinch. But eventually cocaine completely outstripped its rivals in popularity, because the substance could be readily obtained, and because its effects were produced quickly and certainly by the simple process of sniffing into the nose.

To supply the demand for this drug a steadily increasing clandestine traffic was established, and flourishes despite the concerted efforts of Federal, State, and local authorities. In short, the South in trying to correct a bad condition, has created one

infinitely worse, and one absolutely beyond the power of the authorities to suppress or even control.

Laws aimed to suppress illicit liquor traffic frequently fail because public sentiment, and public officials, are not in sympathy with the attempt. But such is not the case with the cocaine traffic. Public officials to a man are eager to suppress it, not merely for sentimental reasons, or from a sense of duty, but from the most potent and compelling motive, *fear*—a matter of self-preservation. Yet in the face of this all-powerful incentive for its suppression, the traffic is steadily increasing.

It is usually difficult to put a finger upon the exact cause of any important economic condition—or disease. Nevertheless a mass of evidence all pointing in one direction warrants our drawing certain conclusions about economic conditions and diseases. And in the case of the increasing drug-habits among the negroes and poor whites in the South the mass of evidence indicates that there is a direct relationship between this condition and the present method of controlling the liquor traffic.

It is significant that hospital and police records both show that during the last five years, the period of active prohibitive legislation, drug-habits have increased enormously. And these records are supplemented by concurrent opinions of physicians and officials.

The drug-users themselves are practically a unit in declaring that they began taking the drug because it was more easily obtained than their accustomed beverages. In considering the value of such statements we must, of course, make allowance for the characteristic untruthfulness of the drug habitué. But it is inconceivable that they should all hit upon the same statement without the existence of a groundwork of truth for their assertions. It is improbable, also, that physicians and officials should have reached the same conclusion without adequate reason for their belief.

Moreover, it is most significant that in cities such as Raleigh, Asheville, and Knoxville, where open drinking places have been abolished, cocaine-taking is increasing at an alarming rate. In Knoxville as many as seven cocaine-using women have been haled to police headquarters in a single day. On the other hand in such a place as Memphis, with its 70,000 negroes, where no attempt is made to stop the sale of liquor, there has been only a moderate increase in the number of drug-takers.

The fact that addiction to cocaine is rare among the better classes of whites and negroes is also significant. The offenders are found mostly among the shiftless class of both races; but unfortunately most of the negroes belong to this class, and in some localities represent fully half the total population. The upper classes can, and do, supply themselves with liquor through the agency of the express companies, whose records are open to inspection, and show a traffic in "gallon packages" that beggars belief. But none of these thousands of packages reach the poorer classes, whose financial status cannot ride above the ten-cent "sniff," or the twenty-five-cent pill-box mixture.

It is significant, also, that many persons who formerly found their way into hospitals and jails as alcoholics, now return as drug habitués.

In short, there is no escaping the conclusion from the mass of available evidence, that the enforcement of prohibition has created a demand for, and produced a traffic in, habit-forming drugs among a dangerously large proportion of the lower classes in the South.

No one familiar with the horrors of the cocaine habit will question whether this substitution of the drug for alcohol is a change for the better. In the case of the habitual drunkard, of course, the substitution of the drug for alcohol is a change for the better. In the case of the habitual drunkard, of course, the substitution may be a good one; cocaine will kill him a little quicker. But it is a very different matter in the case of the ordinary temperate negro—the man who would take an occasional drink without ever becoming in any sense alcoholic. It is among this class that cocaine is working real havoc.

The negro does not appreciate that the penalty of taking a few sniffs of cocaine with convivial companions is very different from that of taking a few glasses of beer under the same circumstances. Like most normal white men, he can take liquor, or leave it alone, as he chooses; and unless he is tainted mentally he does not become an alcoholic. But it requires no mental taint to produce a cocaine fiend; and once the negro begins to dabble with the drug he is doomed. For there is no such thing as an "occasional" or "moderate" cocaine user. The line is very sharply drawn between the total abstainer and the "fiend," without any intermediate condition.

Rightfully, of course, the control of the cocaine habit, and conditions producing drug-habituation, belong to the domain of medicine just as surely as does the control and treatment of other forms of mental abnormalities or epidemics. But unfortunately some of the causes of cocainism are so hopelessly entangled with political issues that mere questions of what is right, or best, are completely subordinated. So that the physician must view with such complacency as he can the sight of a race being decimated by the abuse of a useful drug, until the tide of political contention has spent itself, or shifts to some other field of activity. The wisdom of this political policy is about on a par with that of calling in the surgeons to patch up the wounded after a battle, instead of averting the battle itself.

## BRAIN ABSCESS DUE TO THE BACILLUS COLI COMMUNIS.*

By E. P. BERNSTEIN, M.D.,

NEW YORK.

THE rarity of an abscess of the brain due to the *Bacillus coli communis* becomes evident when we peruse the literature of this subject. Its pyogenic properties in other organs is all too common, but as the causative factor of a pus focus within the cerebrum, no case has as yet been reported.

In a careful review of the American and German textbooks and monographs on this subject, no instance is quoted or reported of this nature. McFarland in his "Textbook upon the Pathogenic Bacteria" credits the *Bacillus coli communis* with causing suppuration in the intestines, appendix, kidney, bladder, urethra, bile ducts, gall-bladder, liver, uterus, peritoneum, heart, lungs, pleura, meninges, and tonsils, and also with causing a bacteriemia. This list is typical of that found in the other English and American bacteriologies.

The representative German book "Kolle and Was-

*From the Pathological Laboratory of Lebanon Hospital, New York City.

sermann" make no mention of this organism as occurring within the brain. They quote the colon bacillus as having been isolated as the cause of the following lesions: abscess of the skin, laparotomy wound infections, perirectal abscess, peritonitis, pyothorax, uterine inflammations, periurethral abscess, kidney abscess, pyelitis, perinephritic abscess, perivascular abscess, penitis, pyosalpinx, ovarian abscess, cystitis, inflammation of the bile ducts and gall-bladder, pneumonia, myelitis, meningitis, and septicemia, no mention being made of brain abscess.

Because of the above facts the following case should be placed on record:

Case.—A. M., Italian, 24 years old, was admitted to the Lebanon Hospital on January 22, 1912, in the service of Dr. Cowen. Six weeks before admission he had had a running ear, but this only persisted for a short time and then caused no further trouble. He entered the hospital complaining of pain in the chest, headaches, pain in the limbs, and sleeplessness. A few days before admission he had a chill followed by fever and profuse greenish expectoration. Examination revealed nothing but sibilant and sonorous rales over both lungs. His temperature during the first few days varied between 99° and 103°, pulse between 80 and 92, and respirations between 24 and 26. His blood pressure was 134. Leucocyte count showed 4,800, with a polynuclear predominance of 64 per cent. Upon the fifth day of his stay in the hospital his left ear began discharging a thick greenish pus and the patient complained of a decided increase in the severity of his headache. Three days later this discharge ceased, but the headaches persisted in their severity and the patient vomited. For the first time a slight tenderness of the left mastoid process was noted. During the next twenty-four hours the patient became stuporous and vomited again, and the following day, (January 31, 1912) died.

For the last five days his temperature had been steadily declining, reaching before death 97.6°, and the pulse progressively slowed to 58. Lumbar puncture ten hours before death gave 30 c.c. of clear fluid under high pressure, showing an absence of a fibrin net, a slight increase of albumin, a prompt reduction of Fehling's solution, and a sterile culture. Search for the tubercle bacillus was negative. Cell count of the fluid showed 79 per cent. polynuclear and 21 per cent. mononuclear elements. On this day the left pupil became larger than the right, while the Kernig and Babinski signs were positive on the left side. The report of the ophthalmologist (Dr. I. Heller) was as follows:—Left eye—Moderately dilated pupil, which does not react to light. Disc outlines are edematous and vessels markedly congested, the edema extending more below and to the right side. Center of disc clear and distinct; macular region shows nothing abnormal. Right eye—Pupil normal in size but reacts sluggishly to light. Outlines of disc distinctly hazy. Vessels markedly congested. Center of disc clear as is also the macula. Less swelling than on left side. A bacteriological examination of the pus from the ear showed a typical *Bacillus coli communis*.

Autopsy, January 31, 1912. Permission for head only. Skull and brain: Brain showed in its entirety the effects of extreme pressure—the fissures and convolutions being leveled. The ventricles are distended by an abnormal amount of clear fluid. Within the posterior part of the left temporosphenoidal lobe and separated from the cortical surface by a considerable layer of intact brain tissue, is lodged an abscess the size of a hen's egg. The pus is of a sanguinopurulent color and has a very foul odor. The petrous portion of the left temporal bone shows no caries on its cranial surface nor is the dura adherent to it. The tegmen tympani is grayish in color. When chiseled off the middle ear, the epitympanic space and the mastoid antrum were found filled with purulent material, of dense consistency and gritty feel. Only a fragment of an ossicle, the incus, was found. The remainder had been destroyed by caries. Aside from the uppermost cavity (the antrum) the remainder of the mastoid process consisted of unaffected cancellous tissue. Bacteriological examination of the pus from the abscess showed a pure culture of *Bacterium coli*.

The mode of conveyance of the germ must have been by way of the lymphatics. The possibility of a direct traumatic infection of the brain can be excluded. While we know that a brain abscess can develop many years after a cranial injury, yet in this case no history of such an injury could be obtained. Equally untenable is the supposition that the bacteria were conveyed by the blood stream, either as infected emboli or as a manifestation of a bacteriemic condition. So also the possibility of an antecedent infection in the antrum of Highmore, ethmoidal bone, or a purulent phlebitis of a cranial sinus, with or without a meningitis, are excluded by the autopsy findings.

Unquestionably a causative relationship exists between the colon infection in the middle ear and a similar infection in the cerebrum. The path of conveyance, however, is not so evident. Here we fail to find a thrombosis of the petrous sinus of the temporal bone, with its subsequent meningitis and brain abscess. We are therefore compelled to consider this a case of lymphatic transmission from the middle ear directly to the brain.

64 West Eighty-third Street.

---

**Bazin's Disease.** Sir Frederic Eve reports the case of an unmarried woman aged 31 years in whom the trouble began as a hard swelling on the outer side of the left leg, which broke down and discharged. An ulcer formed, which gradually spread. When the author first saw her in March, 1913, there were two thin oval cicatrices on the outer side of the lower third of the left leg. At the lower and outer margin of these cicatrices was a rim composed of irregular pit-like ulcerations covered with flabby granulations. The general appearances were those of a serpiginous ulcer. There was also a very small ulcer on the inner side of the same leg. The patient appeared perfectly healthy, and a Wassermann reaction was negative. The ulcerated areas were excised and skin-grafts were applied. At the same time the affected part was exposd to the *x*-rays. As a result of this treatment complete healing took place. Later a few pit-like ulcers reappeared, but they healed after applications of pure carbolic acid and fomentations of 1 in 5,000 watery solution of biniodide of mercury, and the patient returned home. About three weeks subsequently the small ulcer on the inner side of the left leg broke down again, and a sore appeared on the right leg. Small areas of the margins of the scars on the outer side of the left leg also broke down. While in the hospital she has been treated by *x*-rays and has been kept in bed.—*Proceedings of the Royal Society of Medicine.*

**Suture of Wound of the Heart.**—At a recent meeting of the Surgical Society of Paris Lenormant reported the case of a man who had received a gunshot wound on the right side of the chest to the outer side of the mammary line. On account of the smallness and rapidity of the pulse a diagnosis was made of a penetrating wound of the heart. The author resected the first costal cartilage, then the fourth and fifth costal cartilages on the right side, and the right of the sternum. The wound in the pericardium was discovered, the latter was opened and emptied of clots, and a wound in the right ventricle of the heart was sutured. No search was made for the bullet nor for the spot of its egress from the heart. There was a perforation of the lung, which did not bleed, and which was let alone. The operative wound was closed without drainage. The patient made a perfect recovery.—*Gazette des Hôpitaux.*

**Acute Infective Hepatitis.**—Francesco Rodano states that this condition was first described as a complication of dysentery by Remlinger in 1900. The clinical picture closely simulates that of hepatic abscess, the differential diagnosis being revealed only on the operating table. The author reports a case of this condition in a girl aged twenty years. The temperature is remittent or intermittent, the liver is enormously enlarged, there is pain referred to this organ, and there is a leucocytosis with an excess of sudanophiles.—*Rivista Critica di Clinica Medica.*

## THE COAGULATION OF BLOOD AND THE THYROID GLAND.

COMPARATIVELY little is known regarding the variations in the coagulation time of the blood in different morbid conditions. There is even no general agreement as to the normal coagulation time, some authorities placing it as low as two minutes and other equally competent observers assuming ten minutes as the interval that elapses before a drop of blood begins to clot. These differences of opinion are to be attributed partly to the diverse forms of apparatus used for the determination of coagulation time, partly to the differences of surrounding conditions such as atmospheric temperature and pressure, and partly to the personal equation of the investigator. The practical value of the determination of coagulation time has been most clearly perceived in hemorrhagic conditions in which this time is greatly prolonged. A shortened coagulation time which is sometimes observed in pneumonia is regarded of serious prognostic omen. In diseased conditions of the thyroid gland important changes in coagulation time have been observed. Kottmann and Lidsky pointed out a delayed and weakened coagulation in exophthalmic goiter, and a hastened and intensified coagulation in conditions of hypothyroidism. Kocher applied this knowledge in the differentiation between states of hyperthyroidism and states of hypothyroidism in patients suffering from goiter.

Inasmuch as it is frequently difficult to determine in a goitrous individual whether a condition of excessive thyroid function or one of diminished thyroid function exists, the above differential coagulation test, if valid, becomes one of eminent clinical importance, for upon this test may be based a rational surgical or medicinal treatment. This test has been subjected to a critical analysis by Julius Bauer and Marianne Bauer-Jokl, who employed for this purpose the abundant goitrous material of the Innsbruck clinic. They present the important results of their investigation in the *Zeitschrift für klinische Medizin*, Vol. 79, Nos. 1 and 2.

The apparatus which they employed, because of its simplicity and availability for routine clinical work, deserves more than passing mention. It is the instrument recently devised by Fuld. This consists of a metronome, to the pendulum of which there is attached a U-shaped glass tube. The drop of blood to be examined is allowed to fall into one of the arms of this tube and then by a rapid rotating motion imparted to the latter the blood is pushed into the horizontal portion. A small leaden ball is then introduced at the other end of the tube. The pendulum is at once set in motion, each swing corresponding to a second of time, and as long as the drop of blood remains fluid the leaden ball rolls along the bottom of the tube. But as soon as coagulation sets in, the motion of the ball stops. The number of excursions of the pendulum that have occurred until the leaden ball becomes stationary represent the coagulation time in seconds. The authors find that under normal conditions this time is two or three minutes.

By means of this apparatus the coagulation time of the blood was determined in a large number of cases of goiter, and was found to be increased in all of them, whatever may have been the actual functional condition of the thyroid. In conditions of hypothyroidism, as in cretins and cretinoids, the delay in coagulation is more pronounced than in the thyrotoxicoses. It is not possible to differentiate between hyper- and hypothyroidism by means of the determination of the coagulation time. A diminution of the clotting capacity of the blood occurs in most diverse alterations in the blood and glandular systems, in general neuropathic conditions, and in the so-called "status hypoplasticus." In all of these conditions a diminished coagulation power coincides very frequently with a lymphocytosis or mononucleosis and sometimes with an eosinophilia.

The authors observed in three cases following excision of a goiter and resection of the thymus, an improvement in the coagulating power of the blood. The administration of thyroid extract in doses that are not too large results in certain cases in an improvement in the clotting property. In a case of hemophilia associated with infantilism of thyroid origin, thyroid administration restored the practically vanishing power of coagulation. Before this treatment was instituted a drop of blood had not clotted at the end of fourteen hours, but after the administration of thyroid extract a specimen of blood clotted at the end of twelve minutes. The explanation of the greatly prolonged coagulation time that is observed in disturbances of the internal secretions and in the "status hypoplasticus" may possibly account also for the deficient coagulating power observed in hemophilia. The suggestion is made that the fundamental disturbance may lie in the enzymatic processes in the blood. These may also be at fault in the delayed coagulation that is present in nephritis, in various types of anemia, and in certain diseases of the liver.

The results obtained in the Innsbruck investigations are unquestionably of practical importance. They furnish a valid basis for the administration of thyroid extract in all conditions associated with a diminished coagulability of the blood.

## ANOMALOUS RENAL ARTERIES AND VEINS.

A REPORT on this subject of especial value and interest to the surgeon was made by Rupert (*Surg. Gyn. and Obst.* Nov., 1913), who examined 50 cadavers and found that 35, or 70 per cent., of the

number showed a unilateral or bilateral anomaly of the arteries or veins, or both. The kidneys were removed in the dissecting room under Rupert's personal supervision. There were 49 males and one female subject. Both kidneys were normally placed in every instance. No movable, pelvic, or horseshoe kidneys were found, nor was there congenital or post-operative absence of the kidney on one side. These kidneys, therefore, would presumably be found to conform to the textbook normal as regards blood supply. Rupert found upon careful dissection, however, unilateral or bilateral anomalies in the arterial supply in 34 cadavers, while in one other case there was an anomalous condition of the veins only. As Rupert quite properly remarks, most of the textbooks on anatomy make little if any reference to the anomalies of the renal blood vessels. In the last edition of Cunningham, for instance, we find nothing whatever in the main description of the kidney regarding anomalous blood vessels, and it is only upon turning to the section upon "Surface and Surgical Anatomy" that one finds the subject discussed. Here we find merely the following statement: "When the inferior pole of the kidney receives a special blood supply, either directly from the aorta, or from the renal artery, the abnormal vessel may, by passing either in front or behind the superior part of the ureter, cause the latter to be so kinked over the vessel as to cause a secondary hydronephrosis." Nothing whatever is said regarding anomalous veins. Rupert quotes W. A. N. Dorland as follows: "No abdominal arteries are so irregular in their distribution as those which supply the kidneys," and follows this with a quotation from Senator to the effect that "reduplication of one or both renal arteries is a rare condition * * * without significance." Another quotation of especial interest is one from W. J. Mayo, who reported that in "20 out of 27 cases of hydronephrosis operated upon by them anomalous blood vessels were present and the obstruction in each instance was where the blood vessels crossed the ureteropelvic juncture * * * the vessels passed to the lower pole of the kidney and varied from the size of a knitting needle to that of the radial." Another quotation is to the effect that anomalous vessels are found most often at the upper pole. In the face of these conflicting observations and statements, Rupert's findings have an added interest. Extra polar arteries had the following distribution: To the superior pole only, 17 cadavers—12 right, 7 left; to the inferior pole only, 9 cadavers—7 right, 2 left; to superior and inferior pole, same side, 8 cadavers—2 right, 6 left; superior and inferior, both sides, 0. In these 34 cadavers 44 kidneys had anomalous arteries—11 right, 13 left, 10 both sides. The veins did not share the frequency of anomalous distribution, since abnormal veins were found in but 9 cadavers, 11 kidneys being affected—7 right, 0 left, 2 both sides. Among the features of special cases should be noted that in one cadaver having an extra artery to each superior pole the arteries were of the axis type; that on the left side giving off three branches and that on the right two; while in another each superior axis artery gave off three branches. In one case a vein ran from the right renal vein to the transverse fissure of the liver; in another, a vein extended for about 2½ cm. from the left renal vein, where it bifurcated, one branch penetrating the substance of the second or third intervertebral disc, the other branch anastomosing with the lumbar veins. In two cases the spermatic veins emptied into the renal veins on both sides. Two specimens showed that one of the anomalous arteries, in each specimen, made one complete twist around the renal vein, or *vice versa*, and in each instance the artery was as large as the radial. This was an especially interesting condition since the renal plexus of nerves surrounds the artery, and a very slight twist would give all the symptoms of a Dietl's crisis without its being possible to demonstrate a movable kidney clinically. Rupert's conclusions, which are certainly justified, are as follows: "That anomalous renal vessels occur more frequently than is generally supposed; that anomalous veins are as important to consider as anomalous arteries; that while anomalous veins are not as frequent as anomalous arteries, and their presence increases the hazards of renal operations, especially in a nephrectomy; that on account of the thinness of their walls they give but little if any more resistance to traction than a small adhesion, and as pulsation is absent, an anomalous vein is difficult to differentiate from an adhesion unless it can be drawn into the field."

While it is probable that but rarely would so many anomalies be found in a series of one hundred kidneys examined in this way (45 per cent.), it is, nevertheless, astonishing that more stress is not laid upon the comparative frequency of abnormal vessels in the textbooks. Those who have done a great deal of kidney surgery have learned, often after a bitter experience, to be constantly on the watch for abnormalities in blood supply; but in his first nephrectomy the inexperienced man, who has been taught to regard these abnormalties as so rare and of so little consequence that their description is relegated to a foot-note, is as likely to have a case with anomalous arteries of the axis type at each pole as is the expert surgeon. The danger of uncontrolled hemorrhage in the former circumstance is obvious, and if death occurred it could be properly charged, in part at least, to faulty teaching.

## A NURSE PRACTICE LAW.

THE New York State Nurses' Association is endeavoring to standardize the education of the nurse. This movement was endorsed in October, 1913, by the New York State Federation of Women's Clubs at their annual meeting in Buffalo. It is to be recalled that the bill which was introduced into the New York State legislature last winter by Senator Seeley was bitterly and effectively opposed because the bill sought, by legislation, to limit the right to use the word nurse as a title to those who had been duly licensed. At present there is a law which protects the title, registered nurse, or the abbreviation, R. N. It is pointed out by the Nurses' Association that this

title in usage does not safeguard the public in its discrimination between the fitly trained and the unfit nurse; that the public is confused by the many terms which are in general use such as "certified," "trained," "graduate," "domestic" and "practical." At the instigation of the Nurses' Association of New York State practically the same bill will be introduced into the legislature now in session. In the pamphlet which the Association is circulating it is shown that it is necessary to use simply the word, nurse, in defining a practitioner of nursing just as it was found necessary to use simply the words physician, dentist, and veterinarian in the statutes relative to the professions of medicine, dentistry, and veterinary medicine. The majority of nurses are employed through registries which, very often, are commercial and, from a business standpoint, find it necessary to recommend and to obtain employment for any one, regardless of qualifications, who may have paid the fee for registering. Physicians and families do not always ask a nurse whether or not she is a graduate of a hospital. Sometimes the question is put in such a way that a nurse, who may have been only a probationer in a good hospital, may be able to answer truthfully that that is where she received her training, without disclosing the fact that she was only a probationer. Some physicians will oppose this bill because they frequently like to call in as nurses, women whom they know to be well qualified to care for some of their patients, although these women may not have had hospital training. Sometimes it is desirable to call in such women or men because they do not charge as much as regularly trained nurses. The Nurses' Association believes that the physicians should face this squarely and truthfully and should designate such nurses as attendants and should tell the families that they are well qualified to care for the patient in question but that they are not nurses in the sense that this word will be used if the bill becomes a law. One of the special objects of the proposed bill is the stoppage of the graduation of so-called nurses by institutions in no way connected with hospitals. The graduates of such schools and institutions will be prevented from using the title, "nurse," alone or with qualifying terms.

It is not intended that the proposed law shall be an instrument for prosecuting a mother for nursing her child, or a maid for nursing her mistress, or any one for nursing any one else so long as the title, "nurse," is not used professionally. The definition in the bill reads: "To practise as a nurse, within the meaning of this article, shall include the care of the sick or injured as a nurse or registered nurse." Under the provisions of the bill any one may nurse or care for the sick or injured without going contrary to the proposed statute so long as he or she does not call himself or herself a nurse. It would seem that the definition of the practice of nursing could have been written into the bill so as to make its meaning clearer and at the same time not bring out the opposition which it in all probability will. We would suggest the following definition: "To practise as a nurse, within the meaning of this article, is to give professional care to the sick or injured and to hold one's self out as having been taught, trained, or educated to give such care and to call one's self a nurse, with or without qualification." There should be an exemption clause for the nurses in the U. S. Services. For the most part the bill is carefully drawn and fixes only a safe and sane standard of education and practical training for the profession of nursing.

### The Citizen and the Public Health.

In these days the citizen of his own initiative, much more frequently than was formerly the case, takes an intelligent interest in matters concerning public health. He has come to realize the fact that his cooperation is required in order that the health of the community may be best conserved. He is now beginning to understand the inherent truth of the old adage that prevention is better than cure, and moreover, in many instances is willing to put his own shoulder to the wheel so that the most efficient preventive measures may be put into effect. Still the average citizen needs a considerable amount of spurring ere he can be brought to understand the essential importance of his cooperation in all public health questions. Therefore it is eminently fitting that his duty and responsibility in this direction should be impressed upon him as often and forcibly as possible. A. M. Stimson of the Public Health Service has done this, in Supplement No. 4 to the Public Health Reports. In this pamphlet he points out clearly, the duties of a citizen as an individual and as a member of the community at large and aptly remarks that if the nation as a whole only took as much interest in its health as it does in politics or baseball we should have cleaner politics and more time for baseball. John W. Trask, Assistant Surgeon General U. S. Public Health Service, in reprint No. 150 from the Public Health Reports, covers practically the same ground and urges upon each citizen of this country that it is a manifest duty he owes to himself, his family, and the entire community to pay attention to the way in which matters relating to the public health are managed. Great progress has been made in public health throughout the civilized world in recent years, and the results have been striking but it cannot be doubted that if each individual felt it to be his duty to concern himself in the question that the advance would be yet more remarkable.

## News of the Week.

**City Death Rate.**—A sudden rise in the death rate of New York City for the week ending January 24, broke the low mortality record of nearly a year. The rate for the week was 14.64 per thousand of population, representing a total of 1,567 deaths. For the corresponding week of last year it was 14.19 per thousand, with a total of 1,461 deaths. The greatest increase in the number of deaths as compared with previous weeks occurred in those due to organic heart disease, pulmonary tuberculosis, and acute respiratory diseases.

**For Cancer Research.**—The New York Homeopathic Medical College and Flower Hospital recently announced that it had received a gift of $25,000 from Dr. Lambert Suydam of this city, the

money to be used in research into the cure of cancer.

The New York Skin and Cancer Hospital has issued an appeal for 500 milligrams of radium, which it is suggested may either be given outright or loaned to the institution for a term of five years. The trustees of the hospital feel that since it is devoted exclusively to the treatment of cancer, it should be given an opportunity to make an exhaustive study of the therapeutic value of radium. If the substance is obtained it is proposed to begin a series of investigations, to extend over five years, at the end of which time the results will be announced. The radium will be used in the treatment of surface and benign growths, especially those of the face; after operations by the knife, in order to destroy any cancer cells remaining, and in deep-seated and malignant cases for the purpose of clinical study.

**Radium Control Bill.**—The plan for Government control of radium-bearing ores which may hereafter be found on the public domain and for the construction of a Government reduction plant is outlined in a bill prepared for introduction into Congress. It provides that all public lands of the United States on which radium-bearing ores are located shall be subject to exploration and occupation under the mining laws, on condition that the United States shall have the exclusive right to purchase part or all of the product of such lands to the amount of public need; it authorizes the Government to construct and operate plants for the extraction of radium as it may desire; it authorizes the Government, through the Secretary of the Interior, to buy radium-bearing ores mined from the public lands at prices to be fixed by the Government and based upon semi-annual investigations of the cost of production and reasonable profits to the miners; and it permits the Federal Government to buy radium from other sources than the United States and to sell the by-products of radium production in the Government plant and to dispose of the radium extracted there in such manner as will best subserve the public welfare. It is believed that the terms of the bill will satisfy all those interested in the questions.

**Warship Quarantined.**—The new battleship *Arkansas*, one of the largest in the United States navy, was quarantined last week in the Navy Yard at Brooklyn, N. Y., because of an epidemic of diphtheria and sore throat among the crew, numbering in all 1,000 men.

**Seaside Hospital Begun.**—The construction of the new Seaside Hospital at Telawanna Park, Rockaway, for the building and equipping of which the Association for Improving the Condition of the Poor raised a fund of $257,000 seven years ago, was begun last month. The fund has been held in trust since 1906, the association waiting for the city to accept its offer to construct and equip the institution, on condition that the city would provide a suitable site on the ocean front, and would assume the ownership and responsibility for the conduct and maintenance of the hospital. Not until last winter, when the city purchased the Seaside Park at Rockaway, was it able to comply with the terms of the gift. The institution, which will, it is hoped, be ready by May, 1915, will have accommodations for 150 children suffering from non-pulmonary tuberculosis. The entire plant will comprise a four-story structure fronting the ocean, and eight pavilions, each 138 by 142 feet, extending at right angles to this main building, the whole having a capacity of 1,000 beds, the cost being estimated at about $2,000,000. For the present the association will erect as its gift to the city, the administration building, two of the pavilions, and a power plant. The remainder of the institution as planned will be built as need arises and money becomes available.

**Smallpox at Niagara.**—One hundred and twenty-seven cases of smallpox were reported at Niagara Falls, N. Y., up to January 28, and the Canadian Department of Public Health has instructed its inspectors to prevent any resident of the city from boarding trains for Canada unless he is able to show a certificate of recent vaccination. The New York State Board of Health is urging the wholesale vaccination of the children in the public schools of the city.

**To Honor French Mother.**—President Poincaré of France is entertaining a proposal to decorate Mme. Théodore Amet of Paris, the mother of 22 children, all of whom are living, with the Cross of the Legion of Honor.

**Typhus Fever on Ellis Island.**—After having been landed on Ellis Island, a case of typhus fever was discovered among the steerage passengers on the steamship *Rochambeau* which arrived in New York from Havre on January 27. Another case developing among the passengers of the steamship *Belvedere* under observation on Hoffmann's Island, on January 31, made the seventh imported case of the fever which has been noted at Quarantine since January 7.

**Colonel Gorgas Confirmed.**—The United States Senate on January 30 confirmed the nomination of Col. William C. Gorgas as Surgeon-General of the United States Army.

**Centenarian in New Jersey.**—Mrs. Priscilla Inslee, said to have been the oldest woman in New Jersey, died at her home in New Brunswick on January 30, a few days after celebrating her 102d birthday.

**Medical School Dinner.**—Two hundred and fifty physicians attended the dinner of the faculty and directors of the New York Post-Graduate Medical School held at Delmonico's last week, and listened to appeals for the endowment of medical colleges in order that their teaching staffs might be enabled to devote all of their time to instruction and research. Among the speakers were Dr. J. F. McKernon, president of the school, and Dr. William H. Welch of the Johns Hopkins Medical School.

**Mt. Sinai Hospital.**—At the sixty-first annual meeting of the hospital, held on January 25, announcement was made of the gift of a plot of ground measuring 100 x 175 feet, on Fifth avenue and Ninety-ninth street, directly across the street from the hospital. This completes the site needed for the enlargement of the present plant. The building fund has already received subscriptions up to the sum of $1,000,000; it was hoped that an additional $500,000 would soon be subscribed.

Announcement was also made of the retirement from active work of Dr. Arpad G. Gerster, visiting surgeon for thirty-four years, and of Dr. Julius Rudisch, visiting physician for thirty-nine years. In recognition of their long services Dr. Gerster was presented with a silver tea service and Dr. Rudisch with a silver vase, and both were made consultants to the hospital.

**Dr. Christian R. Holmes** was installed as Dean of the Medical College of the University of Cincinnati, O., on January 16. Addresses were made

by President Dabney of the University and by Dr. William H. Welch of the Johns Hopkins Medical School.

**Farm for Convalescents.**—The Young Men's Christian Association of New York is planning to establish on a tract of ground owned by the association near Kingston, N. Y., a farm to which men recovering from illness and too weak to return to work, can be sent while convalescing.

**Conference on Race Betterment.**—At the meetings of the First National Conference on Race Betterment, which were held in Battle Creek, Mich., on January 8 to 12, 1914, 400 men and women were present, comprising the first representative group of scientific experts ever gathered in America for the purpose. The program constituted a widespread study of all phases of evident race degeneracy and the advocacy of many reforms, some of the suggested improvements being frequent medical examination of the well, outdoor life, biological habits of living, open-air schools and playgrounds, etc.

**Mesericordia Hospital.**—This institution has recently become a general hospital with a capacity of 400 beds. At a recent meeting of the medical board the following officers were elected: *President*, Dr. William Shannon; *Secretary*, Dr. Daniel J. Donovan.

**Lectures on Chiropody.**—The School of Chiropody of New York announces a series of lectures to be given at the school on Saturdays, commencing February 7, on the diagnosis and care of various disorders of the feet.

**German Surgical Congress.**—The Forty-third Congress of the German Society of Surgery will be held in Berlin from April 15 to 18, 1914, at the Königl. Hochschule für Musik, under the presidency of Prof. W. Müller of Rostock.

**French Medical Congress.**—The XIV Congrès français de Médecine, organized by the Association des Medécins de langue français, will be held in Brussels from September 30 to October 3, 1914, inclusive. The officers of the Congress are Professor Henrijean, president; Professor Bordet and Professor Vandervelde, vice-presidents; Professor René Verhoogen, secretary-general, and Dr. Godart-Danhieux, treasurer. The following questions will be discussed: (1) Syphilis of the cardiovascular system. (2) The lipoids. (3) The therapeutic value of artificial pneumothorax. (4) Vaccine therapy in general, and of cancer and typhoid fever in particular. The address of the secretary-general is 22, rue Joseph II, Brussels.

**Dr. George E. Brewer** was appointed by the Trustees of Columbia University on February 2 to be professor of surgery in the College of Physicians and Surgeons, in succession to Dr. Joseph A. Blake, resigned. Dr. Brewer, who was graduated from the Harvard Medical School in 1885, has been professor of clinical surgery in the College of Physicians and Surgeons since 1904. Dr. Brewer has also been appointed attending surgeon to the Presbyterian Hospital.

**Incorporate Jurisprudence Society.**—The American Association of Medical Jurisprudence of New York, which is devoted to the study and advancement of the science of medical jurisprudence, has recently been incorporated under the laws of New York State. The membership is limited to 200. Dr. Reynolds Webb Wilcox is president of the association.

**Medical Society Elections.**—New Haven (Conn.) Medical Association: Annual meeting on January 21. Officers elected: *President*, Dr. Willis H. Crowe; *Vice-Presidents*, Dr. Alfred G. Nadler, and Dr. F. B. Standish; *Secretary*, Dr. Charles E. Sanford; *Treasurer*, Dr. T. V. Hynes.

Hartford (Conn.) Medical Society: Annual meeting on January 5. Officers elected: *President*, Dr. Everett J. McKnight; *Vice-President*, Dr. Frederick T. Simpson; *Secretary*, Dr. Arthur H. Griswold; *Assistant Secretary*, Dr. Amos T. Harrington; *Treasurer*, Dr. Philip D. Bunce.

Washington County (R. I.) Medical Society: Annual meeting at Providence on January 8. Officers elected: *President*, Dr. Harold D. Kenyon, Westerly; *Vice-Presidents*, Dr. H. B. Potter, Wakefield, and Dr. Asa S. Briggs, Ashaway; *Secretary-Treasurer*, Dr. William A. Hillard, Westerly.

Center District-Merrimack County (N. H.) Medical Society: Annual meeting at Concord on January 13. Officers elected: *President*, Dr. C. E. Butterfield, Suncook; *Vice-President*, Dr. Russell Wilkins, Concord; *Secretary-Treasurer*, Dr. Pearl T. Haskell, Concord.

York County (Me.) Medical Society: Annual meeting at Biddeford on January 7. Officers elected: *President*, Dr. Joseph W. Gordon, Ogunquit; *Vive-President*, Dr. Joseph M. O'Connor, Biddeford; *Secretary*, Dr. Arthur L. Jones, Old Orchard; *Treasurer*, Dr. Charles F. Traynor, Biddeford.

Contra Costa County (Cal.) Medical Society: Annual meeting at Oakland on January 19. Officers elected: *President*, Dr. Ursa S. Abbott, Richmond; *Vice-President*, Dr. E. W. Merrithew, Martinez; *Secretary-Treasurer*, Dr. Dr. E. B. Fitzpatrick, Martinez.

**Obituary Notes.**—Dr. J. Harvey Dew of New York, a graduate of the University of Virginia, Department of Medicine, Charlottesville, in 1867, and a member of the American Medical Association, the Medical Society of the State of New York, the New York County Medical Society, the Academy of Medicine, and the Society of the Alumni of the City Hospital, died at his home on January 26, aged 70 years.

Dr. Edgar Doak Capps of Fort Worth, Tex., a graduate of the College of Physicians and Surgeons, New York, in 1891, one of the founders of the Fort Worth School of Medicine, and professor of diseases of the brain and nervous system in that institution, and a member of the Texas State Medical Society, died at his home suddenly, from heart disease, on December 19, aged 46 years.

Dr. Henry Lorenz Obetz of Detroit, Mich., a graduate of the Cleveland University of Medicine and Surgery, Cleveland, O., in 1874, formerly professor of surgery and dean of the Homeopathic Medical College, University of Michigan, an attending physician to Grace and St. Mary's Hospitals, Detroit, and a member of the American Medical Association, and the Michigan State and Wayne County Medical Societies, died at his home on December 20, aged 62 years.

Dr. W. M. Holladay of Hampden-Sidney, Va., a graduate of the Hospital College of Medicine, Louisville, Ky., in 1885, and a member of the Medical Society of Virginia, died at his home on December 20, aged 49 years.

Dr. Ephraim Magoon of St. Louis, Mo., whose back was broken by a fall at his home some weeks before, died at the Mullanphy Hospital on December 29, aged 71 years.

Dr. GEORGE F. FORBES of Worcester, Mass., a graduate of the Boston University School of Medicine, Boston, in 1874, died at his home after a short illness, from pneumonia, on January 3, aged 82 years.

Dr. MATTHEW W. SMITH of Brooklyn, N. Y., a graduate of the Bellevue Hospital Medical College, New York, in 1873, died at his home on January 8, aged 60 years.

Dr. JAMES ROY MCINTIRE of Carlisle, Ky., a graduate of the Southwestern Homeopathic Medical College and Hospital, Louisville, in 1902, died suddenly, at his home, on January 9, aged 32 years.

Dr. JOHN G. OOSTERBECK of Hysham, Mont., a graduate of the Rush Medical College, Chicago, in 1904, and formerly assistant physician at the Peoria State Hospital, Peoria, Ill., died in Chicago, on January 8, aged 37 years.

Dr. WILLIAM H. HANFORD of Brooklyn, N. Y., a graduate of the Cleveland University of Medicine and Surgery, Cleveland, O., in 1853, died at his home on January 19, aged 89 years.

Dr. RAYMOND W. WILSON of South Bethlehem, Pa., a graduate of the Medico-Chirurgical College of Philadelphia, died at his home from pneumonia, on January 17, aged 34 years.

Dr. ISAAC B. LOOS of Trenton, N. J., a graduate of the Jefferson Medical College, Philadelphia, in 1888, and a member of the American Medical Association, the Medical Society of New Jersey, and the Mercer County Medical Society, died at his home on January 13.

Dr. WILLIAM PENNY of Brooklyn, N. Y., a graduate of the University of Louisville, Medical Department, Ky., in 1872, died at his home from pneumonia on January 21, aged 83 years.

Dr. THOMAS PEDDIE of New York, a graduate of the Bellevue Hospital Medical College, New York, in 1875, and for many years a medical inspector of the New York Department of Health, died at his home on January 20.

Assistant Surgeon WILLIAM H. ULSH, retired, United States Navy, a graduate of the University of Pennsylvania, Department of Medicine, Philadelphia, in 1893, was instantly killed in an automobile accident near his home at Selinsgrove, Pa., on January 21, aged 43 years.

Dr. GEOFFREY R. BOURKE of New York, a licentiate of the Royal College of Surgeons of Ireland in 1869, and a member of the New York State and County Medical Societies, died at his country home at West Sayville, L. I., from pneumonia, on January 23.

Dr. CHARLES E. SMITH of Whitesboro, N. Y., a graduate of the Albany Medical College in 1858, and a member of the Medical Society of the State of New York and the Oneida County Medical Society, died at his home, from apoplexy, on January 25, aged 77 years.

Dr. JOHN A. STRATTON of Newman, Cal., a graduate of the University of Michigan, Department of Medicine and Surgery, Ann Arbor, in 1882, and a member of the Medical Society of the State of California and the Stanislaus County Medical Society, died at his home, after a long illness, on January 14, aged 56 years.

Dr. WILLIAM L. SMITH of Springfield, Mo., a graduate of the Kentucky School of Medicine, Louisville, in 1893, and a member of the Missouri State Medical Association and the Greene County Medical Society, died at his home, after a brief illness, from pneumonia, on January 20, aged 47 years.

## Correspondence.

### OUR LONDON LETTER.

(From Our Regular Correspondent.)

AEROPLANES FOR CONVEYING WOUNDED IN WARFARE—RECENT ADVANCES IN TROPICAL MEDICINE—TUBERCULOUS RHEUMATISM—MEMORIALS OF LISTER AND PAGET—OBITUARY.

LONDON, January 16, 1914.

THE use of aeroplanes to the Army Medical Service was discussed at the British United Service Institution on Wednesday afternoon. Lieut.-Col. J. F. Donegan, R.A.M.C., gave the lecture. He said an expert not long ago told him that airships were likely very soon to be used for the transport of troops on the field. In that case the lecturer had little doubt they would be available for the removal of the wounded who could sit up, considering their rapidity and independence of roads or bridges, and would not hamper or delay the movement of troops. Provided with the necessary stability they would be as useful in savage as other warfare. For scouting for wounded on the battlefield we did not at present realize their utility. His experience was that he had never found it difficult to locate wounded by day, but it was very much so by night. If aeroplanes proved useful at night they would have to be fitted with installations for wireless telegraphy and searchlights, but the rate at which they travel was likely to be misleading. Distances in miles were accurate enough for marching troops, but when it came to the question of the helpless and disabled even yards counted. After his lecture Colonel Donegan showed by lantern slides the working of an aero operating table.

Colonel Massey quoted M. Furman as to the practibility of building aeroplanes to transport four wounded men in a lying position and described experiments made at the recent French maneuvers with a flying corps to indicate to the ambulance corps where there were wounded. The brigadier general thought when aviation was practical for the army medical service field ambulances would have to be supplied with such aeroplanes as might be necessary. He doubted if an army in the field would allow a machine to fly over their position, as it might carry valuable information. Lieutenant-General Bethune, who had presided, considered Colonel Donegan had shown his proposal would be of great use in the cause of humanity. It would also clear away traffic which was in the way of the fighting troops. He urged, therefore, that aeroplanes of proper type should be supplied for both the medical and the fighting service.

"Recent Advances in Tropical Medicine" was the subject of a lecture at the Hunterian Society on Wednesday by Mr. James Cantlie. The claim was taken by Mr. William Ettlas, who mentioned the lecturer's reputation as a practical observer of the subject who had traveled all over Asia to study it since thirty years ago he gave up the position of surgeon to Charing Cross Hospital to go to Hong Kong, where he founded the school of medicine.

Mr. Cantlie said the starting point of the recent advances in tropical medicine was Sir Patrick Manson's discovery in Formosa that mosquitos were the carriers of the filaria which were the cause of malaria. His early experience in cholera research in Egypt as one of the party of twelve (sometimes called the twelve English apostles) who went there in 1884 without previous experience and

without microscopes. None of them caught cholera, although two or three of a German party who also went contracted the disease and one of them died. The bacillus had been shown to be carried by the flea. As regards plague, it was carried by the rat flea as had been proved from place to place, but the human flea carried it from man to man. Mr. Cantlie said the Book of Samuel contained a description of plague which shows that the writer knew it was spread by rats, but the world had forgotten it and so had to find it out again and learn once more that as usual the old Hebrew writer was correct. Tertian fever was the next disease mentioned by the lecturer, who said that 100 or 150 years ago almost everyone living on the banks of the Thames suffered from enlarged spleen and until the district was drained there was no place more infected with malaria. He declared the world was standing still as to prevention. England had got rid of malaria by drainage and other places should tackle the problem. Concerning trypanosome diseases Mr. Cantlie said the *Glossina morsitans* had now spread into Rhodesia; they were not at present pathogenic but nobody knew when they might become so; their present harmlessness might be due to their not yet having met with a carrier.

Asking why women hated every kind of vermin Mr. Cantlie said it was not because they were ferocious but because right back to the time of Moses vermin carried diseases. In reference to pellagra he said that five or six years ago it was practically unknown in the United States, but now there were some 50,000 cases. It had also appeared as a new disease in England and might become a serious problem. In conclusion he urged that much more should be done to give full effect to the discoveries already made.

Rheumatic symptoms are so frequently observed in the course of various chronic diseases, especially those of infective origin, as to excite little attention, though in some they have been used to differentiate a variety, *e.g.* gonorrhea. In France they distinguish tuberculous rheumatism, but here the phrase is not common. An old practitioner now retired says that in his student days tuberculous glands in the neck were called scrofulous or strumous and not more indicative of tubercle or phthisis than some other signs of general ill health which were grouped under the name of scrofula or struma. He remembers being instructed by his family's practitioner soon after he had begun to study for the profession as to this affection, the two words being synonymous, and he was told among other things that almost all diseases presented modifications in patients of a strumous constitution, that word being used as freely as tuberculous now is; scrofulous or strumous rheumatism was at that time no unusual phrase. What then are the relations, if any, now recognized between rheumatism and tuberculosis?

At a recent meeting of the Royal Society of Medicine a paper was read which may help to answer this question. The author was Dr. Nathan Raw of Liverpool Infirmary and he related a case which he considered an illustration of what French writers call tuberculous rheumatism and which is the only one he has met with in over 6,000 cases of pulmonary tuberculosis, although it is common, he says, to see cases of tuberculous arthritis attacking one or perhaps more joints, he regards it as "most rare to meet with a multiple arthritis of the smaller joints in the hands, fingers, wrists, and ankles in the course of tuberculosis." Many may perhaps think that 1 in 6,000 might very well pass as accidental. But you may be interested in a few points of the case which is related in full in the *Lancet* of the 3d inst. A girl of 13 had tuberculous glands, slowly progressive and painful, and general health failing, loss of weight. Breaking down five years later the glands were opened and contents evacuated—removal being impossible on account of adhesions. A month after operation painless, rapid effusion into right wrist, a week later into left also and soon after swelling of all metacarpophalangeal joints. Little pain, temperature 102° night and 99° morning for ten days. Salicylates no effect. Fluid aspirated from wrist, no bacilli found, injected into a guinea pig which developed general tuberculosis in four weeks. Cultures from its spleen developed growth corresponding to bovine tubercle. The rabbit similarly affected but less severely. Cultures from the neck glands of the patient also produced bovine tuberculosis in a guinea pig and a rabbit.

Dr. Raw began tuberculin treatment in very small doses T. R. (human), gradually increasing, with good effects. Examination of the joint fluid revealed excess of lymphocytes which, as he observes, is in favor of tuberculosis as opposed to polymorphonuclear leucocytosis which occurs in true rheumatism. His case and two others he saw (one in Washington, one in Berlin) all followed neck gland affections, which he thinks almost always caused by bovine bacillus, while pulmonary tuberculosis is mostly due to human bacillus. So bovine seems more likely than human bacillus to find its way into the blood and the joints.

The memorial tablet to Lord Lister at Kings College was unveiled on the 14th inst. by Lord Rayleigh, who gave an address in which he spoke of his personal appreciation of one he regarded as among the greatest scientists.

The centenary of the birth of Sir James Paget was celebrated on Sunday last at Great Yarmouth, his birthplace, with great enthusiasm. One of his sons, who is now Bishop of Stepney, preached the sermon in the parish church. He mentioned that his father in early life had to contend with extreme poverty and in later life had several attacks of pneumonia. Interesting relics were presented by the family to the Corporation of Yarmouth.

Dr. John Meredith, J.P., M.O.H., died on the 10th inst. in his 82d year, at Wellington, in Somerset, where he had practised for about fifty years. In earlier life he had been in the Indian medical service. He contributed on malaria to the *Indian Medical Gazette*, 1867-73.

Dr. Cuthbert Clibborn, J.P., medical inspector of the Irish L. G. B. for about seventeen years, has died at the age of 67. He graduated in arts and medicine in Dublin in 1869.

Dr. J. C. Ferguson, who had filled various appointments in Belfast, including the physiciancy of the Women's and Children's Hospital, while talking to a colleague on the 6th inst., suddenly fell dead, to the grief of many.

Dr. John Gorman of Bangor also met with a death which may be termed sudden on the morning of December 27. Feeling not very well when getting up he said he would take another hour's rest, and when called, as he had arranged, was found to be dead.

## OUR PARIS LETTER.

(From Our Regular Correspondent.)

FRENCH CONGRESS OF UROLOGY—PERICYSTITIS—PROSTATECTOMY—CHRONIC SPERMATOCYSTITIS—A NEW ANTIGONOCOCCIC VACCINE—LUMBAR EXPLORATION IN RENAL TUBERCULOSIS — RADIOGRAPHY IN RENAL LITHIASIS—RICHET AND THE NOBEL PRIZE IN MEDICINE—OBITUARIES: LUCAS-CHAMPIONNIÈRE, JABOULAY, LEDOUBLE.

PARIS, January 1, 1914.

THE French Congress of Urology recently held its sessions. The subject of pericystitis was presented in a paper by Aversencq of Toulouse, who classified pericystitis anatomically into (1) extracystitis or suppuration in the space of Retzius or prevesical space formed in front of the prevesicopelvic fold of peritoneum; and (2) pericystitis proper, which develops behind the latter fold in the cellular tissue surrounding the bladder. Infection may give rise to the different forms of inflammation that are found in the cellular tissue of other parts of the body. The different stages of inflammation found in both types of pericystitis are as follows: serous, scleroadipose, multiple minute abscess formation, extensive circumscribed abscess, and diffuse phlegmon. Of frequent occurrence are the cases of scleroadipose pericystitis localized at the terminal portion of the ureters and around the seminal vesicles, the remains of a prostatitis or of a more or less latent vesiculitis.

The pathogenic cause is either within or without the bladder. In the acute cases the extravesical origin is the more frequent, such factors as appendicitis and disease of the female adnexa being operative. It is otherwise with the chronic type of pericystitis which is usually the sequence of prostatitis, vesical calculus, or infections complicating a stricture. With this recognition of the origin of pericystitis diagnosis is facilitated and the treatment is guided. The treatment should first of all be directed against the cause. Pericystitis is frequently revealed at autopsy or at operation. The forms of extracystitis more easily accessible justify a methodical surgical intervention apart from the treatment of the cause, namely, hypogastric section with or without perineal or vaginal counter-drainage.

In the discussion P. Legueu referred to the difficulty of diagnosis of certain forms of pericystitis which, particularly if they occur low down, may simulate malignant disease. Bazy stated that certain cases of partial pericystitis may be accompanied by intense painful manifestations, and may give rise to phleboliths which form false calculi of the ureters. P. Pousson of Bordeaux pointed out the dangers of the scleroadipose type of pericystitis: it is one of the causes of fistula-formation after cystotomy, and transforms the bladder into an inert reservoir.

Prostatectomy was the subject of a number of interesting communications. Pauchet referred to the good results he had obtained in prostatics with renal insufficiency, in placing the patient upon an exclusively fruit diet and in performing the operation in two stages. Carlier likewise favored the two-stage operation in cases of infection of the bladder. Marion has obtained good results in cases of rebellious prostatitis by means of suprapubic prostatectomy. The operation is relatively simple inasmuch as each lobe is removed separately.

In chronic spermatocystitis Georges Luys has obtained the best results by means of catheterism and dilatation of the ejaculatory ducts. These are frequently strictured and therefore massage is ineffectual. Catheterism with minute flexible stilettes is simple and without danger if performed with the aid of the Luys urethroscope, provided that one has carried out a preliminary treatment of the verumontanum, the "mirror of the seminal vesicles," which always shares in their infection. The procedure of catheterism provides an efficient treatment for a condition which is frequently neglected and is always dangerous. Thevenot of Lyons perceives the danger of the vesiculitis that occurs in the course of hypertrophy of the prostate. The vesiculitis makes the prostate more adherent and less easily enucleated. It also increases the risks of hemorrhage and of postoperative infection.

A new antigonococcic vaccine was described by Nicolle of Tunis. This vaccine has the advantage over other preparations in causing neither a local nor a general reaction. The results obtained have been particularly encouraging in the general complications such as ophthalmia and rheumatism. It is too early to decide as to the results obtained in the urethritis itself, or in its urinary complications.

In renal tuberculosis if catheterization of the ureters is impossible, Carlier of Lille prefers to catheterization following suprapubic cystotomy exploration on both sides through the lumbar region. Legueu likewise does not resort to suprapubic catheterization because of the bad effects of general anesthesia upon the renal function. It may be added that in many of the cases lumbar exploration is not necessary if the direct vision cystoscope of Luys is employed. This enables one to catheterize the ureters even in cases of severe cystitis and when the capacity of the bladder is greatly reduced.

Radiography cannot be regarded as an infallible procedure in all cases of renal lithiasis. J. Belot mentions cases in which the $x$-rays have not revealed the presence of calculi, which were not sufficiently opaque for the $x$-rays or which had the same opacity as the surrounding media. Radiography of vesical calculi has likewise given uncertain results. Arcelin of Lyons finds that about 50 per cent. of vesical calculi are not detected in radiographic examination. This method of investigation is of value only in special cases as in diverticular calculi.

Professor Charles Richet, who received the Nobel Prize in Medicine, fully merited this distinction, which crowns a career of scientific endeavor. The learned world rejoices in the honor paid to the great French physiologist.

The death of Lucas-Championnière removed one of the pioneers of modern surgery who was among the first to put into practice the teachings of Lister. His ability was unquestioned. His writings on hernia, on trephining, and on amputations alone were sufficient to place him among the highest rank of surgeons. He was a pioneer in the field of kinetotherapy. He pointed out the danger in immobilizing injured joints, and the advantage of early passive motion and massage in lesions in and about the joints. An honorary surgeon of the Hôtel Dieu, a member of the Academy of Medicine, and an officer of the Legion of Honor, Championnière died in the zenith of his activity, in the midst of apparent health.

The death of Professor Jaboulay of Lyons, occurring on the day following that of Poncet, was

the result of a railway accident at Melun. One of the best of French surgeons, Jaboulay was rated for his remarkable sangfroid and daring. With an independence of mind that closely bordered on barbarity Jaboulay rarely took part in medical congresses or reunions. His name is associated with the operations of exothyropexy, of excision of the sympathetic in exophthalmic goiter, and of vascular anastomoses. During recent years Jaboulay devoted his attention mostly to cancer.

An accident was also the cause of death of Professor F. A. Ledouble of Tours. His life had been devoted to the study and teaching of anatomy. Like that other great anatomist, Farsbeuf, Ledouble modestly retired from the main current of medical activities. His preference was for the study of anomalies. He showed their importance in pathology. He was the author of the proposition which has really acquired the force of an axiom: organs that are malformed are predisposed to disease. His researches and writings dealt successively with the variations and anomalies of the genital apparatus, of the nervous system, of the cranium, the bones of the face, of the hair, and of the spinal column. He also published medico-literary studies on Rabelais and upon Bossuet as anatomist and physiologist.

## OUR LETTER FROM THE PHILIPPINES.

(From Our Regular Correspondent.)

### THE PLAGUE CAMPAIGN IN MANILA—POOR PHYSICAL CONDITION OF PHILIPPINE LABORERS—EMETINE IN DYSENTERY—LEPROSY IN BILIBID PRISON—SPORADIC CHOLERA—HYGIENE OF TOBACCO FACTORIES.

MANILA, P. I., December 22, 1913.

THE regular monthly meeting of the Manila Medical Society was held at 8:30 P. M., December 1, at the College of Medicine and Surgery. The first paper, entitled "The Recent Plague Campaign in Manila," by Doctor Thomas W. Jackson, gave a brief history of the plague outbreak which began in Manila in June, 1912, and the last case of which occurred on September 20, 1913. He expressed himself as being a firm believer in the possibility of reducing the number of rats; in other words, he thought that anti-rat measures effectively carried out had a decided effect in reducing the number of rats in spite of the allegations that the rat breeding soon replaced them and that the number of rats in a city was very much governed by the amount of food supply available. On account of the success of the measures against plague he stated that the observations with regard to seasonal flea breeding and humidity and rainfall had very little value. He also stated that the experience had in Java with rats nesting in bamboo and these nests being frequently associated with plague in human beings was also confirmed in Manila. During the campaign he mentioned that over 10,000 tons of refuse and filth had been removed from the sections in which plague had occurred. Over 2,000 houses were rat-proofed. Multiple house infections practically never occurred, with one or two exceptions in which rat-proofing measures were not promptly carried out.

The next paper, entitled "Some Observations on the Examination of Filipino Laborers for the Hawaiian Sugar Plantations" was read by Doctor A. M. Saleeby. He reported that over 10,000 laborers had been examined and of this number only 64 per cent. were passed. The larger number of rejections, about 26 per cent., were due to beriberi. The second cause was that of heart disease. He also reported nineteen cases of backward dislocation of the elbow joint. These, he concluded, were caused by improper manipulation during childbirth. In the discussion which followed, Dr. Heiser stated that the large number of heart cases reported coincided very closely with the results which were obtained in the examination of masters, mates, pilots, etc., in the Philippine Marine Service and that the percentage of rejections from this cause is very much higher in the Philippines than in the United States.

The next paper was entitled "Experience With Emetine Hydrochloride and Ipecac in the Treatment of Dysentery at the Philippine General Hospital," by Dr. David Willetts. He supported his statement by saying that in all 133 cases had been treated and of this number ipecac had proven more efficacious than emetine hydrochloride and that the use of neosalvarsan had proven very satisfactory in eliminating the ameba from the intestinal tract. The emetine hydrochloride proved most successful in promptly relieving the clinical symptoms of dysentery, but the ipecac and the neosalvarsan were more successful in finally freeing the intestines of ameba.

From time to time cases of leprosy have occurred in Bilibid Prison. It may, therefore, be of interest to record the dates that the prisoners entered Bilibid and the dates upon which leprosy was first recognized in such prisoners. In all, there have been three. The first one entered the prison on June 15, 1903, and did not show any symptoms of leprosy until January, 1911. In the meantime, however, he had been detailed from June, 1907, to July, 1907, on public works, where he might have been exposed to leprosy. He was also an inmate of the Iwahig Penal Farm Colony, where exposure to leprosy was possible, from February, 1909, until January, 1911. The second case was admitted in April, 1904, and was detailed on public works at Camp Overton, in Mindanao, in April, 1905. In September, 1905, he escaped, but was captured two weeks later. In July, 1906, he was returned to Bilibid. In September, 1908, he was detailed on public works on the Island of Corregidor, but returned to Bilibid during May, 1910. During July, 1911, a definite diagnosis of leprosy was made and he was transferred to the Leper Hospital. The third case was admitted in March, 1911, was constantly in Bilibid Prison, and showed unmistakable evidences of the disease on November 5, 1913, and was transferred to the San Lazaro Hospital on that date. From the foregoing it will be apparent that the first two cases could have contracted the infection outside of Bilibid Prison and that the last case occurred within the generally recognized incubation period of the disease.

Sporadic cases of cholera still continue to occur in Manila. Most of them are found among the deaths which are attributed to other causes, but upon careful bacteriological examinations being made cholera vibrios are discovered. On December 18th five cases were reported from Calivo, in Capiz Province, and shortly afterward several cases were reported from Banga and New Washington, both of which are towns in the same province not far from Calivo. Deaths suspicious of cholera have been occurring in the Island of Penay for the past two months. The original case could not be traced to any outside source.

After considerable opposition from the tobacco

factories, an ordinance which provides for the proper sanitation and cleanliness of such factories was passed by the Municipal Board of Manila. Heretofore, the laws and regulations for factories which exported cigars were fairly satisfactory, but there was no adequate provision for those which made only product for domestic consumption. With this new ordinance, however, all factories are brought under the regulations and a great improvement will no doubt take place.

**1. Mortality of Hereditary Syphilis.**—A. Post says there is a tendency to disregard syphilis in this country. It is supposed to be a disease of older countries, and rare in this; it is thought to be confined to those who go to seek it and to have no interest for those whose lives are blameless. If one accepts the death returns of the country as final, one may well say that the fatalities from syphilis are negligible. The author proceeds to show that this belief is not founded on facts, and gives the experience of those in charge of the Dermatological Clinic of the Boston Dispensary to emphasize this point. Futher attention is drawn to the failure to give a census of syphilitics, although attempts have been made to approximately learn the amount of disease in the country. The figures fall between 15 and 20 per cent. It is then from its numbers of no inconsiderable importance, but the failure to rightly report syphilis means an addition in the report of something else. It falsifies the report. Syphilis is an infectious disease, conveyed by the most innocent kiss or even careless handling. Probably at least one-half of the syphilis in the world is innocently acquired, and even the sinners are our brethren. The desire to attach disgrace to all victims of the disease leads to concealment and difficulty in study.

**3. The Suspicion of Malignancy.**—H. Lilienthal learned the following interesting facts from a study of 2,000 histories in his case books: (1) There were 86 cases of malignancy or 4.3 per cent. Investigations in five large New York hospitals showed Dr. Lilienthal that in 2,000 consecutive surgical ward patients there had been: In Mount Sinai Hospital, 84 cases of malignancy, or 4.2 per cent. In St. Luke's Hospital, 82 cases of malignancy, or 4.1 per cent. In Presbyterian Hospital, in 2,345 cases in 1912, 127 cases of malignancy, or 5.4 per cent. In Roosevelt Hospital, 2,000 patients, 129 cases of malignancy, or 6.4 per cent. In New York Hospital, 200 patients, 34 cases of malignancy, or 1.7 per cent. Now, counting all these groups of approximately 2,000 cases together we have in 12,345 patients 542 instances of cancer, or 4.39 per cent., which means that one in every 22 surgical patients had cancer. (2) Of his own 86 patients 65 had never been operated upon and may be called new cases; (3) of the 65, 10 were sarcomata, 55 carcinomata; (4) of the 65, 35 were in men, 30 in women. Questions regarding the promptness or tardiness of surgical consultation elicited this information. (5) It was discovered that after the first discovery of a tumor, or after the first suspicious symptoms, the men had waited on the average 12.2 months before consulting the surgeon, the women 11.9 months. Now it is known that very few persons discover or suspect the presence of cancer until the symptoms are very pronounced, or until there is a tumor of considerable size; also, that such a tumor, with or without symptoms, had probably been in existence for say six months before it was discovered. So that it may be assumed that cancer patients do not come to the operating table until at least a year and a half after the onset of the malignant disease.

8. Gas Oxygen Anesthesia. A. H. Miller.
9. Treatment of Disease in the Aged. A. Orenstein.

**5. Insanity in Latent Bright's Disease.**—G. W. McCaskey notes that the etiological relationship of Bright's disease to insanity is undoubtedly merely incidental, and not in any sense specific. Nevertheless, the occasional incidence of insanity in the course of latent Bright's disease acting probably as an immediate cause is a clinical fact demanding careful recognition. Three cases of this kind are reported. McCaskey's purpose in reporting these cases is to emphasize the importance of a most thorough investigation of renal conditions in all cases of insanity, especially in those fulminant types in which the cyclonic character of the psychosis is liable to make examination very difficult and to distract attention from a proper study of somatic conditions. It will be readily seen that the deleterious influence of the retention of waste products associated with Bright's disease would make the chemical recognition of these conditions of the utmost importance from every point of view in practically every type of insanity.

**6. Abdomen Strengthening.**—S. Lewis says that it has been often pointed out that much of man's structure is better adapted to a quadruped than to a biped. While most of us would not care to retrograde in these matters, we recognize that many, probably half at least, of our illnesses are due to sedentary habits and erect posture. Because of the latter, weak structures are overworked, strong ones weaken from disuse, organs sag, intestinal and other tubes kink, dependent veins overdistend, toxins are generated. The work of Sir Arbuthnot Lane is most illuminating in this regard. Lewis recommends methods for toning and strengthening the abdomen, divided into active or gymnastic and passive or manual. The apparatus to be used is described and a prescription is given detailing the various exercises to be employed.

**9. Treatment of Disease in the Aged.**—A. Orenstein lays down a regimen of hygiene and diet for the treatment of disease in the aged. It is pointed out that the aged require less food of all kinds, because they utilize less. Overfeeding, or rather a normal adult's ration, overtaxes their digestive powers and floods the blood with effete products which the kidneys and other emunctories cannot handle. Drinking water should be encouraged and baths, which should be taken regularly, should be neither hot nor cold, of short duration, and preferably in the evening when they conduce to a good night's sleep. Fresh air and exercise are indispensable. Clothing should be light, warm, loose, and of woolen material. The feet should be well protected. Cathar-

tics are the only class of drugs which are administered to the aged in larger doses than to middle-aged adults, but not with proportionate safety. General weakness is the complaint common to all. Since we have no specific against physiological old age we must adapt our treatment to each individual. Cod liver oil in dram doses is beneficial to some. Strychnine does good by stimulating digestive processes as well as the circulation. Alcohol in the form of whiskey may be given in small doses to stimulate the appetite. To conclude, the treatment of disease in senility should be conservative and without drastic changes in the *modus vivendi*.

**3. Recovery in Pneumonia.**—L. Hektoen, from a study of the mechanism of recovery in pneumonia with special reference to the crisis, in which he reviews the recent literature on the subject reaches the following conclusions: The cure of pneumonia results from the destruction of the pneumococci in the lungs and in the blood. This is accomplished mainly by phagocytosis, probably to some extent also by extracellular processes. The predominating general defensive reactions in pneumonia are leucocytosis and the production of antibodies for pneumococci, especially opsonins, and these appear to be specific for the group to which the infecting pneumococcus belongs. In rapidly fatal cases the defensive reactions are inadequate to destroy the pneumococci, which persist and multiply in the lungs and in the blood. In favorable cases the pneumococci are destroyed more or less rapidly when the antipneumococcal reactions reach a certain height. It may be assumed that lysis results when the destruction takes place more gradually. Crisis is the effect of prompt destruction. In both cases, but demonstrated more clearly in crisis, there is an excess of free antibodies in the blood.

**10. Sulphuric Ether Lavage.**—G. De Tarnowsky, in reporting thirty cases treated by the Souligoux-Morestin method of sulphuric ether lavage of the peritoneal cavity says that his attention was called to the method during a recent visit to Paris, where it is used in five hospitals as a routine measure in all laparotomies. He began using it in his abdominal operations in the latter part of August, 1913, in both private and charity cases with uniformly gratifying results. He describes the technique as follows: After removal of pathological tissue free pus is carefully wiped out; then ether is freely poured into the abdomen and is allowed to come into contact with all of the viscera in a case of general peritonitis. The viscera are literally washed in ether, hence the term "lavage." As much as a quart of ether has been used. After having remained in contact with the abdominal organs for from two to five minutes, it is mopped out by means of gauze sponges, and the abdomen is closed with one small drain. In circumscribed peritonitis the pus cavity, having been wiped out, is filled with ether and the abdomen is closed without drainage. In pelvic peritonitis, ether soaked sponges are applied to all involved surfaces, and then two ounces of ether are poured into Douglas' pouch and the abdomen is closed without drainage. The immediate effect of ether thus applied is to cause a momentary capillary contraction, followed by hyperemia of the viscera. There is a moderate formation of carbon dioxide in the abdomen, evinced by a bubbling sound and the escape of bubbles from the surface of the ether. Ether is slowly absorbed by the serosa; this is proved by the fact that no change in the anesthesia of the patient has been reported. De Tarnowsky's thirty cases included three cases of gangrenous appendicitis with general peritonitis, four cases of localized abdominal peritonitis, two of pelvic peritonitis, and one of acute cholecystitis with adhesions, in which the bactericidal action was very apparent. The remaining cases were not acutely septic. In 75 per cent. the postoperative pain and restlessness were lessened and were not increased in the remaining 25 per cent. He is convinced that when this method is used there is less pain than is ordinarily encountered and there was no mortality in this service.

**12. Pellagra.**—G. M. Niles admits that the etiology and pathology of pellagra are still obscure, but is of the opinion that the disease is more manageable than it is sometimes considered to be and gives the details of his method of treatment. Hygienic measures are the same as those employed in other exhaustive diseases, with two exceptions. The first is that alcoholic beverages given in any amount seem to be highly detrimental and the other is that sunlight should be avoided as the actinic rays appear to have an especially irritating effect, which is most marked in early spring. As to diet he prohibits corn bread and corn products unless he knows that they are perfectly fresh and that the corn has undergone no heating. Until the "zeist" theory is completely disproved we owe to our patients this precaution. With regard to other dietetic measures it must be kept in mind that the disease is not primarily localized in the gastrointestinal tract, but is a centralized irritation, plus the effect of toxins eliminated through that tract. The early diarrhea is mainly of central origin and to some extent compensatory, and, therefore, does not call for a very limited regimen. Woody vegetables and foods yielding a large residue in the bowel are mechanically contraindicated and should be replaced by other nourishing foods. The flesh proteins are especially well borne. Sweet milk is valuable when it agrees with the patient, but advising immoderate amounts without determining the digestive ability is bad practice. During the whole course of pellagra the patient should be nourished to the limit of assimilation and will generally bear and care for more aliment than when the stomach is similarly irritated as the effect of other disorders. He administers hypodermically iron arsenite and sodium cacodylate on alternate days for about two weeks in small doses. After the acute symptoms seem to be controlled he gives two injections weekly for several months. Sometimes when the patient is anemic he uses iron preparations instead. Internally he employs a combination of saturated solution of potassium iodide and Fowler's solution in proportion of five of the first and three of the second, beginning with five drops in water, three times a day, gradually increasing a drop a day until arsenical symptoms appear. If gastric or intestinal intolerance occurs the proportion of Fowler's solution is lessened. The diarrhea is controlled by bismuth, betanaphthol, etc., and if severe by tannigen or opium; kerosene oil enemas have also been found useful. For the infrequent constipation, the milder cathartics only should be used. The details of the local lesions are given. He

does not favor the employment of salvarsan. Hydrotherapy has proved beneficial in many cases, and Niles holds that it should be resorted to in some form, in almost every case. The value of keeping up the spirits of patients and of controlling the pellagraphobia which embarrasses the treatment is emphasized. He thinks that by suitable suggestion the nerve degeneration can be to some extent repaired. His experience has taught him that the prognosis should be guarded in four classes of cases: in persons over fifty years of age; in alcoholics; in persons who change their treatment from one method to another. If, however, the patient is under fifty, will adhere to a fixed line of treatment, and faithfully cooperate with the physician a permanent cure can be expected in the majority of cases.

**3. Early Diagnosis and Treatment of Ruptured Intestine.**—V. Z. Cope points out the fact that while traumatic rupture of the intestine without any wound of the abdominal wall is not frequent it is sufficiently common to call for some definiteness as to the surest guides for early diagnosis and the best methods of treatment. Providing there be no lesion in the chest and that renal trauma is excluded he would submit that it would be advisable to open the abdomen on the suspicion of ruptured intestine if the following conditions be present: 1. When severe abdominal pain persists for more than about six hours after an injury, if the pain be accompanied by either (*a*) vomiting, especially bilious vomiting; or (*b*) a pulse gradually rising from the normal; or (*c*) persistent local rigidity tending to extend; or (*d*) deep local tenderness with shallow respiration; and 2. When abdominal pain is absent or only slight, but the pulse rises steadily hour by hour and the patient is very restless or listless. When marked diminution of the liver dullness occurs with any of the above symptoms, or if there be signs of free fluid in the abdomen, the indications for operation would be imperative. Since the memorable case of Croft in 1889 the recognized treatment of ruptured intestine has been by operation. After describing the technique of the operation Cope says the main points of differences between surgeons are the toilet of the peritoneum. The questions at issue are: 1. Should general or local irrigation be adopted or should dry sponging or even no cleansing of the peritoneum be attempted? 2. Should drainage be adopted? The conclusions gathered from a consideration of these methods are: That irrigation with saline solution is inadvisable in cases operated on early, and that with late cases the matter is not of much consequence; and 2, that drainage is possibly the safest plan. Notes of two cases of successful operation for traumatic subcutaneous rupture of the jejunum are given.

**5. Recurrent Intussusception.**—G. G. Turner reports a case of intussusception which recurred three times and was operated upon three times with a successful result. He records another case in which there were evidently a recurrence which underwent "spontaneous reduction." Discussing the question of how the recurrence of intussusception is to be prevented, Turner says that if for any reason recurrence is especially feared, or if it has actually occurred, what can be done? He fancies that to be of much service it would be necessary to fix the bowel to the abdominal wall after separating the parietal peritoneum. If there is any gross pathological condition in the lower ileum not easily removable, then he would be disposed to make a lateral anastamosis. Taking all the circumstances into consideration he does not think it is necessary to take any special means to anticipate recurrence, except, of course, the removal of any causative factor, such as an inverted Meckel's diverticulum. In the rare cases in which the condition recurs it is always amenable to early diagnosis and operation.

**Injuries of Aviators.**—Marx points especially to the forensic aspect of such injuries, which involve both flyers and the public. The author has performed autopsies on two dead flyers. One had fallen as a result of collision in the air. In another case the surmise was that the aeroplane had not been properly constructed. Men who fall from whatever height should present the same appearance, independently of the spot where the fall began. But victims of falls from airships and aeroplanes may sometimes present some added injury, for the airship may have been on fire at the time, and those who fall from a great height on the water have injuries due to submersion added to those due to striking the water. Injuries resulting from aeroplane falls show great uniformity. These comprise fractures of the skull and spine, which, as a rule, cause death instantly. A broken neck or fractured base is occasionally seen. Two persons, man and woman, in the same aeroplane, fell together. The man lived fourteen hours, unconscious. Some of the cervical vertebra had been fractured. The woman was not even stunned and her mind was clear when she reached the hospital. She presented externally a skinned nose, contused left eye, and an extravasation of blood in the right thigh. She was discharged entirely cured in a month. The distance of the fall was but six meters. A man who fell twenty meters died from a forward dislocation of the atlas compressing the cord. Captain J., a Swiss aviator, who fell to his death, showed no external injuries, but those beneath the skin, including fractures, hemorrhages, etc., were extremely numerous. It appears that falling with the machine and being hurled from it, or the turning over of the machine as it strikes, is responsible for such injuries as fractures of the arm and collarbone. Since the station was established at Johannisthal, there have been 130 accidents, but only twelve deaths; naturally many of the injuries were of the severest type.

**Theory of Scarlet Fever.**—Cederberg states that von Pirquet's reaction has taught us that measles, variola, varicella, and rubeola are allergic in nature, at least when compared with scarlatina, which thus far has not been shown to belong under this head. The author believes that the rash of scarlatina may be allergic, but that it is very different with the so-called post-scarlatinal lesions, concerning which opinions may vary greatly. Primary scarlatina, aside from the question of allergie, represents a pure toxemia. Is it then possible that the secondary scarlatina involves an attempt at curbing the first by antitoxins? Does their seriousness mean that the counterpoison may be too intense or on the contrary, unable to neutralize fully the original toxins? Do they represent an autoreinfection? The doctrine of streptococcus superinfection is practically ignored by the writer. The author is forced by exclusion to conclude that the primary intoxication lib-

erates antibodies very freely just at the critical point of the disease. It is, of course, at this juncture that the antibodies appear *en masse* and appear very brusquely. If there are germs in the blood, as there must be (despite the statement that the first symptoms represent a pure toxemia), it is possible that they at once seek to leave the blood, and chiefly by the kidneys. To sum up the author believes that scarlatina is due to a certain germ, which, aside from causing toxemia, does no apparent harm, escaping by the kidneys. But the toxin forms some antibody which renders the blood at once uninhabitable, so that the germs rush *en masse* into the tissues, but chiefly to the kidneys, where in large quantities they produce nephritis. They also cause bone and joint and ear lesions.

**On Shoulder Pain in Pleurisy.**—Gerhardt states that but little attention has ever been paid to this symptom, while the abdominal pain from the same affection has been freely studied. The author, after commenting on Mackenzie's finds, gives his own experience. He has seen isolated shoulder pains in four cases. Two were examples of lower lobe pneumonia with pleural irritation, a third of chronic dry pleurisy, while the fourth was dry pleurisy following infarct in a lower lobe. All the patients complained also of diaphragmatic pains. In three of the four cases pressure over the phrenic nerve was felt distinctly. The shoulder pain was felt most acutely in the parts which lie laterally and to the rear of the joint. The skin over these portions was sensitive to pressure. Movement increased the shoulder pains, and in two cases the first diagnosis was rheumatic arthritis. In all four cases there was a pleuritic friction sound over the deepest portion of the lower lobe. The material illustrates the sympathy between the shoulder joint and the lower lobe of the lung. This also leads to the relation of the lower lobes and the diaphragm and to the participation of the phrenic nerve. In diaphragmatic pleurisy, pain in the neck and shoulder sometimes occurs. It thus seems reasonable to connect isolated shoulder pain with diaphragmatic pleurisy, by means of the sensory fibers of the phrenic. A similar explanation might hold true for the visceral abdominal pains of pleurisy. An alleged acute rheumatic arthritis in the shoulder should naturally suggest the necessity of excluding pleurisy.

**Critique of Electrical "Antifat" Cures.**—Rochinhold mentions in particular the methods of Bergonié, Nagelschmidt and Schnée. The former is chiefly discussed, as the last two have only modified Bergonié's technique, and the author has had no personal experience with them. His conclusions are as follows: In Bergonization we have a contrivance for passive muscular motion which may be added to or replace entirely active muscular motion. It is of service when associated with proper diet. Like active exercise it produces free perspiration and melts off the fat, while albumin is gained. It is best not to regard the process as one for physical reduction but for muscular development in the various asthenic conditions, and incidentally the heart.

**Filariasis of the Eye.**—Raubenbusch of Buenos Aires describes a case of this parasitism without a single comment. The patient himself had made the diagnosis without difficulty as the living parasite could be seen in the conjunctiva, near the inner canthus. The author was for referring the patient to a specialist but received the answer that if the worm was not promptly removed it would soon enter the eye, from which it had emerged. This same parasite seemed to have made its way throughout most of the body before reaching the right eye. The author cocainized the eye, made an incision, and drew out the parasite which lived for a time in warm saline solution. When the patient and specimen were shown to the Argentine Medical Society no member present had ever seen or heard of the particular species of parasite (*Filaria loa*) in that part of the world.

**Diabetes and Surgical Affections.**—Karewski concludes as follows: Everyone who comes to a clinic for operation, must be thoroughly examined for diabetes. Every form of the latter affection requires careful consideration from the standpoint of the internist, both during and after operation. Neither the mild forms of diabetes, nor preparative treatment protects one from coma after surgical intervention, and if anything make the prognosis worse. The wounds heal under strict asepsis in any form of diabetes without disturbance. But with wound infection the disease runs a malignant course and increases the dangers of this disease of metabolism. Every operative intervention which is suitable for life saving or restores the capacity for labor, is not only permissible, but represents a demand; but any superfluous bloody intervention should be omitted.

**Behring's Latest Serotherapy of Diphtheria.**—Hahn and Sommer relate the latest steps in the production of a perfect serotherapy of diphtheria. The toxin-antitoxin mixture, injected subcutaneously and intramuscularly, while it leads to a most active production of protective antibodies, is found to be not yet adapted to practical medicine, because the absence of local or general reaction give us no chance to fix a standard of dosage. But when injected intracutaneously a strong local reaction results accompanied by a slight general reaction which gives us an idea of the extent to which the defensive bodies have been increased. In five epidemics and one endemic 633 children were fully immunized without harm. Of this number but two contracted the disease during the epidemic—one in an abortive form, and the other without bacillary finds. A few cases appeared later, running an abortive course. We learn therefore that a protective inoculation can last to a certainty only some ten days.

**Twilight State and Subsequent Amnesia After Slight Concussion of the Brain.**—Meyer describes a most interesting case, summing up as follows: Female, 31, had murdered her four children by drowning. She was apparently sane but her ancestry was very poor. Put to intelligence tests she was subnormal—there was a certain grade of debility. Her married life had been very unhappy and on account of the disposition of her husband, and the increasingly bad prospect for the future, it was thought possible that she killed her children out of love for them. This motive is regarded as quite normal under certain circumstances, it being held that a woman of normal mind may be so wrought up as to commit evil with the best of motives. Before the deed was committed, the woman had sustained from her husband some 20 blows on the head. She was laid up on one occasion with vomiting, vertigo, etc., and no doubt a slight concussion resulted. The immediate effects of the crime and of her future caused not the least disturbance in her mind. On the other hand there was amnesia in regard to the murder and also of a trip taken to her parents' home as a result of the same. That this behavior could be regarded as a "twilight state" with an impulse to murder, in the epileptic sense, was the opinion of the author.

## Insurance Medicine.

**Prognosis of Heart Affections from the Life Insurance Aspect.**—Dr. James MacKenzie says that in the examination of individuals for life insurance, he was the means of rejecting a number because of some heart affection, who have been able to follow their ordinary occupations for many years and who have never suffered from any form of heart failure. This experience led him to seek the reasons why some individuals with certain characteristic phenomena drifted and died, while others seemed little the worse. In his investigations of the subject, it was always necessary to seek the associated phenomena and to note what bearing the cause of the abnormal sign has upon the efficiency of the heart, does it indicate heart failure or foreshadow the occurrence? Heart failure is the inability of the heart to maintain a circulation so efficient that it can meet the strain a healthy, vigorous life demands and is an expression of an exhausted heart muscle. The heart forces may be considered as composed of two kinds—a rest force, strong enough to maintain an efficient circulation when the body is at rest, and a reserve force, brought into action when the body or any part of it is called into activity. The amount of reserve force varies in different individuals, making the standard peculiar to the individual. Heart failure sets in by a limitation of the cardiac response to effort in the first instance, and later, the limitation becomes more and more restricted, until the rest force is encroached upon and dropsy or dyspnea appears. The first evidence of heart failure is entirely subjective and gradually increasing until physical signs appear. The presence of any sign revealed by physical examination, however abnormal it may seem, is of no serious significance as long as it is the only sign present, or as long as there is no limitation of the reserve force of the heart. MacKenzie considers this statement of very great importance in the prognosis of heart affections, especially with regard to life insurance.

Among the most common manifestations of the heart which are to be regarded as abnormal are the irregularities, yet perfectly normal hearts may be frequently irregular in rhythm. The inability to distinguish the grave forms from those which are normal and not serious has led to the assumption that all irregularities are of evil import. There are certain irregularities, such as the youthful type and the extra-systole, present so frequently in healthy people and occasioning no signs of heart failure, that they should never be considered as impairing the prospect of the individual, when they are the only manifestation. If present with other signs, then the prognosis should be based on the other signs, not on the irregularity. Other irregularities, such as auricular fibrillation, heart-block, pulsus alternans, etc., should arouse an inquiry as to how far their cause has embarrassed the heart muscle as they are always the outcome of an actual heart lesion, and are accompanied by other evidences of cardiac disease. It is, therefore, upon the associated evidences that the decision must be made. Murmurs are the second important group of heart affections. With reference to life insurance work, MacKenzie divides them into two great groups: those of no significance, and those whose significance has to be considered and weighed. In the first group are embraced all those which are termed functional, and those in which there is a doubt whether they are functional or not. They are supposed to originate according to their mechanism, as mitral, tricuspid, etc. From the life insurance aspect, when these murmurs are the only phenomena present, they are not to be regarded, or when associated with a harmless type of irregularity, they occasion no concern; but when associated with a limitation of the reserve force, as a weakened heart muscle, the decision should be based on the cause of this inefficiency, which is either a lesion of the muscle or an affection which has impaired the muscle. In the second group are placed all the organic murmurs, and here a variety of conditions is to be found. These should be studied as to whether the causative process is stationary or progressive, and the amount of embarrassment caused the heart muscle. Murmurs indicate a diseased condition of the valves, and usually the process is not quiescent. In cases of heart failure with murmurs, the muscle lesion is the causative agent and not the regurgitation, as supposed by the upholders of the back pressure theory. The point to be considered for prognosis is the appreciation of the condition of the heart muscle, which can be learned only by a full knowledge of how the heart responds to effort. Exhaustion of the reserve force, in a healthy or diseased heart, is always accompanied by sensations of distress, and the premature occurrence of these signs indicates the limitation of the heart muscle. Breathlessness is the most common sign and the one least considered on the ordinary insurance blank. The knowledge obtained in recent years with reference to the irregularities constitutes almost a revolution, and greatly increases their diagnostic and prognostic significances.—Life Assurance Medical Officers Association.

**Chronic Myopia a Disease in the Sense of the Imperial Insurance Law.**—One of the German courts having decided that short sight is an abnormal condition of the body, if the degree is great enough to demand artificial sharpening of the vision—thereby making the summoning of medical aid necessary—there can be no doubt that myopia constitutes a "disease" in the sense of the Law of Sickness-Insurance. If, however, we take account of another passage in the said law, the risk is expressly commanded to wear glasses as a minor requirement. Now in mild degrees of short sight the risk at most invokes the aid of a physician for the time being, the service ending with the prescription for glasses, and the question of earning capacity is usually left as before. But when short sightedness of such a high degree is involved, that further recourse to lenses no longer aids vision, and the earning capacity either fails outright or becomes limited, the question of operation may come up. In such a case we count upon a chronic disease state, which places the subject under the charge of the sick-benefit society. In the matter of invalid revenue it was established that with short and weak sight which continues to develop until such a degree is reached that the earning capacity is estimated at about 25 per cent. the risk must be estimated as incapable of earning in the sense of the Invalid Insurance Law. Aside from short sight the patient's eyes were found normal. Hence it is established that the complainant is both ill and without earning capacity in the sense of the Sick-Insurance Law.—*Zeitschrift für Versicherungsmedizin*, August, 1913.

# Book Reviews.

CASE HISTORIES IN PEDIATRICS. A Collection of Histories of Actual Patients Selected to Illustrate the Diagnosis, Prognosis, and Treatment of the Diseases of Infancy and Childhood, with an Introductory Section on the Normal Development and Physical Examination of Infants and Children. By JOHN LOVETT MORSE, A.M., M.D., Associate Professor of Pediatrics, Harvard Medical School; Associate Visiting Physician at the Infants' Hospital, and at the Children's Hospital, Boston. Second Edition. Price, $5.50. Boston: W. M. Leonard, 1913.

THERE can be no question that the teaching of a subject by means of concrete case histories has distinct advantages over the generalized descriptions of disease. The first edition of this book was greeted as an interesting and lucid exposition of this method in the teaching of pediatrics. In its second edition the book has grown considerably from 341 to 639 pages, and from a discussion of 100 to one of 200 case histories. The later edition covers the entire field of pediatrics and includes a full and detailed chapter on the normal development and physical examination of children. Apart from the vividness and emphasis upon important points which are associated with the concrete discussion of an actual case as recorded in the author's notes, one may point out the full consideration given to the subjects of diagnosis and prognosis, and the ample and detailed discussion of the treatment. No vague generalities are here given. The actual and minute directions in the treatment of each case are set down as they would be given to the parent in the sick room or to the nurse in the hospital ward. The book is fully illustrated with excellent photographic reproductions of actual cases. The type is large, and the paper and binding are of excellent quality. This book should be invaluable to the undergraduate and postgraduate students in pediatrics.

KLINISCHE BEITRÄGE: BEITRÄGE ZUR KLINIK DER INFEKTIONSKRANKHEITEN UND ZUR IMMUNITÄTSFORSCHUNG (MIT AUSSCHLUSS DER TUBERCULOSE). Herausgegeben von Professor Dr. L. BRAUER, Ärztlichem Direktor des Allgemeinen Krankenhauses Hamburg-Eppendorf. Redaktion: für die Originale: Dr. H. SCHOTTMÜLLER (klinischer und bakteriologischer Teil), Dr. H. MUCH (immunitätswissenschaftlicher Teil), beide am Allgemeinen Krankenhaus Hamburg-Eppendorf; für die Ergebnisse: Professor Dr. H. LÜDKE in Würzburg. II Band, I. Heft. Price, 20 marks per volume. Würzburg, Verlag von Curt Kabitzsch, 1913.

THE following articles are comprised in this number: "The Etiology of Poliomyelitis with Special Reference to the Rhenish-Westphalian Epidemic of 1909," by Deusseu; "The Etiology of Suppurative Disease of the Female Adnexa," by Schottmüller and Barfurth; "The Treatment and Nature of Diphtheritic Paralysis," by Römer and Viereck; "Experiences with Krauss' Typhoid Serum," by Gaupp; "Comments on the Article by Carl Römer, 'On Bacteriemia in Abortions and its Clinical and Theoretical Significance,'" by Sachs; "A Reply to the Foregoing Comments," by Römer; "Comments on the Latter Reply," by Sachs, and "Conclusion," by Römer. This number contains also the following collective reviews: "The Rôle of the Bloodvessels in Acute and Chronic Infectious Diseases," by Stadler, and "The Methods in the Preparation and Cultivation of Spirochetes," by Sowade.

CUNNINGHAM'S TEXTBOOK OF ANATOMY. Edited by ARTHUR ROBINSON, M.D., F.R.C.S.E., Professor of Anatomy, University of Edinburgh. Fourth Edition, Enlarged and Rewritten. Illustrated by 1,124 Figures from Original Drawings, 637 of which are Printed in Colors, and Two Plates. Price, cloth, $6.50 net; half morocco, $7.50 net. New York: William Wood & Company, 1913.

CUNNINGHAM'S textbook of anatomy first appeared in 1902 and received almost immediate recognition as a master work on this subject. The rapidity with which it was first recommended and then required in so many of the leading medical schools of the English speaking world was remarkable and could be explained only on the ground of superior excellence as a teaching instrument. Since then the book has enjoyed an ever-increasing popularity, has been kept well abreast of the times by three careful revisions, and now, in its fourth edition, may be considered unquestionably one of the best if not *the* best textbook of anatomy extant. Owing to the deaths of Professors Cunningham, Birmingham, and A. H. Young, changes in the authorship of several of the sections have been rendered necessary. Every section has been revised, some have been partially and others completely rewritten, while the work has been embellished with many new illustrations, more than half of which are in colors. Prof. Arthur Robinson, the editor of the present edition, is Cunningham's successor as professor of anatomy at the University of Edinburgh, and is eminently qualified to carry out the ideals of his distinguished predecessor.

Contrary to a rather firmly established custom, the usual introductory section on histology has been omitted in this work. This seems a step in the right direction since the subject is so large that it can be treated only in the most cursory and unsatisfactory manner in the few pages usually allowed for this purpose. Here the initial section is upon embryology, a subject which deserves the first place in a book devoted to the study of anatomy. This has been contributed by Robinson and embodies the results of the latest researches along this line; furthermore, the description of the development of the human embryo is unusually clear, and made still more so by the employment of more than 100 illustrations, many of which are printed in several colors. Robinson has also revised and partially rewritten the section on the vascular system. Osteology is written by Prof. Arthur Thompson. One of the features which attract the reviewer's attention in this section is the employment of varicolored illustrations to show the method of ossification, the epiphyses, some of the different divisions and processes of certain bones and articulations with other bones. The value of this innovation is particularly evident when one studies the skull as a whole, the part taken even by the elusive sphenoid being shown with remarkable clearness, in both its external and internal aspects. Other sections and their authors are: The Articulations, Prof. David Hepburn; The Muscular System and Peripheral Nervous System, Prof. A. Melville Paterson; Central Nervous System, Prof. G. Elliot Smith; Organs of Sense and the Integument, Prof. Robert Howden; Respiratory System, Prof. Richard J. A. Berry; Digestive System, Prof. David Waterston; Urinogenital System, Prof. A. Francis Dixon; Ductless Glands, Prof. A. Campbell Geddes; Surface and Surgical Anatomy, Harold J. Stiles. It is impossible to devote the space necessary for even brief mention of important points in these sections.

After a quite extensive study of the book the reviewer is impressed with two facts: first, the descriptions are remarkably clear and concise, and this seems to be true no matter what part of the book one refers to; second, the illustrations *illustrate*. In elaboration of this dictum we may say that while there is a profusion of illustrations, it is hard to find one that does not add materially to the correct understanding of the subject under discussion. Furthermore, by the use of many colors in a large part of the illustrations, results have been obtained as to perspective and in showing the relations of adjacent parts to each other which are little short of marvelous. The Basle nomenclature is used throughout the book, but in an unobtrusive manner, the old as well as the new terminology being given. Consequently those who learned only the old names for arteries, muscles, nerves, etc., will have but little if any difficulty in reading this text. It is hard to see where any room has been left for improvement in future editions.

PYORRHEA ALVEOLARIS. By FRIEDRICH HECKER, B.Sc., D.D.S., A.M., M.D., Member of the Academy of Science of St. Louis, Mo.; Consultant at Bell Memorial Hospital of the School of Medicine, University of Kansas, Rosedale, Kan.; Consultant at St. Margaret's Hospital, Kansas City, Kan. Illustrated; price $2.00. St. Louis: C. V. Mosby Company, 1913.

THIS book presents a lucid account of the present-day knowledge of pyorrhea alveolaris. The author regards this disease as the result of constitutional and local exciting causes. The latter lower the vital resistance of the alveolar process, the gum, and the peridental membrane. Nine different varieties of pyorrhea alveolaris are differentiated. The vaccine treatment is described in full, including the technique of the examination of blood smears, the incubation and examination of bacteria, and the preparation of vaccines. The book is, therefore, eminently practical. Its literary garb may, however, be improved upon.

# Society Reports.

## THE PRACTITIONERS' SOCIETY OF NEW YORK.

*Two Hundred and Fifty-eighth Regular Meeting, Held Dec. 5, 1913.*

THE PRESIDENT, DR. WALTER B. JAMES, IN THE CHAIR.

**Treatment of Retrodisplacements of the Uterus.**—Dr. WILLIAM M. POLK read this paper (see page 231).

Dr. BRYANT said he had been much interested in the details of the operation. He did not claim special knowledge, but it seemed to him that the anatomical conditions were very satisfactory. He would like to congratulate Dr. Polk. He hoped the methods would prove as faithful to the trust as they had done in other procedures related thereto.

Dr. GIBNEY asked Dr. Polk if the retroversion of which he spoke was thought to be a common cause of backache in women. He probably knew that with many of the profession the cases of irritability and nervousness were referred to retroverted uterus and menstrual disturbances. These cases went from one doctor to another. If they came under his care he might send them on to a gynecologist to see if the uterus was misplaced or the ophthalmologist to see if refraction was wrong. The rectologist also treated them as sometimes the trouble was supposed to lie in the rectum. He wondered how the question of backache could be settled.

Dr. KNAPP asked if retroversion was associated with general enteroptosis and if it had any connection with the question of child bearing. Many women, those who had a very long narrow chest and a rather protuberant lower abdomen, as in some young girls and unmarried women, seemed to be inclined to retroversion. In the cases of marked enteroptosis that one saw with misplaced stomach and pelvic organs, the lesser curvature of the stomach below the umbilicus, would not that form a factor in the production of a retroversion? Would procedure directed toward relieving the enteroptosis not also relieve the retroversion?

Dr. CONNER asked why the peritoneal cover should be considered a structure that had any textile strength and why it helped to maintain the position of the uterus. He had supposed that it was elastic and had no strength at all.

Dr. ABBE asked what suture material was used.

Dr. POLK said in reply to Dr. Gibney that so far as retroversion was concerned, any congested condition of the uterus, acute or chronic, would give symptoms of backache. When retroversion was present and the uterus was sensitive you would always find backache. It was a sort of general symptom which accompanied congested uterus, no matter what the position. In reply to Dr. Knapp he said that he was not sure that enteroptosis produced retroversion, but there was reason to believe that the condition was caused by intrapelvic pressure. This was, of course, to a certain extent relieved by proper support of the abdomen, just above the pubis; in other words a pendulous abdomen was conducive to the condition of retroversion, and at any rate prevented its relief. With proper abdominal support the position of the uterus was better maintained. There had always been a certain amount of difference of opinion as to the line of pressure that bears on the pelvis from the abdomen, but there was no difference as to what we knew of the sustaining effect of the respiratory movements of the abdomen in the normal abdominal cavity. The movements of respiration undoubtedly had some influence in the position of the organ; when everything was relaxed these movements were lost and we found we were at sea as regarded the right or wrong of the forces determining the position of the organ. In reply to Dr. Conner he said that the peritoneum by itself would offer very inefficient resistance, but when sufficiently backed up it had a considerable degree of resistance, just as, for instance, if you left the sac of a hernia and repaired the muscular structures, you could not be sure of the result. Replying to Dr. Abbe, Dr. Polk said he had been using kangaroo tendon. He thought a lasting material was necessary. Dr. Polk said he had two different cases to report which were sufficient to indicate the advantages claimed for the procedure mentioned in his paper. One was that of a woman who had had retroversion of the uterus for many years. She desired to become pregnant. The uterus had not been treated by pessary because she could not take the necessary time for treatment. The operation just mentioned was performed and this brought the uterus into proper position. Later the woman became pregnant, and she passed through her pregnancy and after parturition she returned for examination. The uterus was still in good position, at a date six months afterwards. The second case was that of a woman who had had many children. This operation was done and the result was wholly satisfactory. The point was that the structures to support the uterus and correct this difficulty should be properly chosen. Attempts had been made by the profession ten or fifteen years ago which were not entirely satisfactory. With the addition of the plication of the structures of the peritoneum lying near the uterus it seemed advantages were afforded. Of course this procedure was open to objections that could be made to others, namely, it did not meet all the difficulties of the situation. But it did strike more fundamentally at the difficulties of the situation. It tried to restore the normal structures upon which the position of the uterus depended. Peritoneal displacements of the pelvic floor might be classed with the herniæ; this was an old story. It seemed to him that the peritoneum should be cared for in the same way as in the treatment of any ordinary hernia, inguinal or femoral. It could be reached in the same way along the lines suggested, so as to lift up the portion of the peritoneal sac implicated in the backward and downward displacements of the uterus. Retroversion was the first step of a prolapse. If you were able to lift up the peritoneal surface of the pelvic floor you were striking at the threatened prolapse. Then if you could shorten up the basic structures that held up the uterus, the lower lines of the broad ligament and posterior attachment of the uterus, you were bringing into play the normal supports. Correct the difficulty at its root and it went further than procedures looking toward the unnatural suspension of the organ.

**Osteitis Fibrosa of the Hip.**—Dr. GIBNEY reported a case recently admitted to the Ruptured and Crippled Hospital, which on first examination appeared to be a sarcoma. On further study, however, the case seemed to be almost identical with one described by Dr. Freiburg of Cincinnati, in a paper on certain lesions related to bone cysts. The result of operation in this case had been, comparatively speaking, a good one. Dr. Gibney had meant to have the boy at the meeting, but the preceding Tuesday he had done an exploratory operation on the boy's hip and had taken a piece of bone out to overcome the deformity. The boy had been placed in plaster from his hip to his toes, so that the patient could not be shown, but would be later. Dr. Whitbeck had, by invitation, brought a patient to supplement this case. Dr. Gibney's patient was shown to Dr. Coley who said the *x*-ray picture suggested sarcoma, but the history was against the diagnosis of sarcoma and, after exposure at operation he said it did not look at all like a sarcoma. In Dr. Gibney's opinion it was a case of osteitis fibrosa. Dr. Whitbeck's case would bear on the subject, although the *x*-ray showed it to be more cystic than Dr. Gibney's. The patient was a boy of 11 years, admitted Nov. 13, who gave a history of 9 years' duration, under treatment all the time, but never before having had to use a crutch. In the hospital they found deformities of adduction and a rotation outward; the position in the third stage. A few days ago he had made an incision over the mass which was an osteitis fibrosa. The adductors were divided and by bringing the edges of the whole together he got a good position. He followed the procedure of Dr. Freiburg as his case corresponded so closely and he had got a very good result. Von Recklinghausen had described this type of case in 1891 and stated that it was a metaplasm rather than a neoplasm.

Dr. CONNER said he would like to ask about the nature of the case; he did not know just what was to be understood by the term metaplasm.

Dr. GIBNEY, replying to Dr. Conner, said it meant replacement by tissue of the same embryological nature. This tissue replaced normal bone tissues by metamorphosis; these changes made the normal bone look very much like bone cysts. Subperiosteal cysts were often benign. He had seen many called sarcoma and treated as such. This case had gone on eight or nine years; Dr. Whitbeck's had gone for four or five. The cases were painless and shortening of the leg was the only symptom. Sometimes the head and neck of the trochanter major and minor were involved or part of the shaft. One of Freiburg's cases occurred in the

tibia; one in the shaft of the femur. These were reported a year ago before the Chicago Medical Society. In Murphy's last volume of clinics he described one that looked like hip disease without the pain. The patient was not lame at all until the adductor became shortened. Dr. Gibney did a cuneiform osteotomy over the deformity as was done by Freiburg with good result. The patient would be shown at the next meeting, with the *x*-ray pictures before and after. Dr. Jefferies, the pathologist to the hospital, had just reported as follows: "The tissue sent by Dr. Gibney shows bone and cartilage both of which exhibit inflammatory changes, the etiology of which does not appear. No neoplasm was observed on section cut. One bit is a portion of perichondrium showing acute inflammation."

Dr. WHITBECK said that the *x*-ray of this case showed a remarkable resemblance to the case presented by Dr. Gibney. The patient, a girl of 14 years, came to the orthopoedic clinic at Bellevue last summer. Her history was that 5 years ago she fell and struck her hip on the left side; there was some pain for about a week but no more trouble until about 20 months ago when she began to limp, the leg becoming shorter; there was no fresh injury at the beginning of the limp and no pain or discomfort. She went to a large orthopoedic hospital a year ago and a spica was applied which she wore for a week. This was taken off at home and she had worn no appliance since. Six months ago the patient fell again, striking the same hip; there was some pain and soreness about the hip; she was admitted to one of the large hospitals and put in bed with extension; she was then transferred to the Island for four months whence she went home, the symptoms having disappeared. There was no pain or discomfort but the shortening and limp continued. She was brought to Dr. Whitbeck last summer because of the limp which was very noticeable when she walked. At the time when patient was first seen by Dr. Gibney, two months previously, there was slight flexion and adduction. Over the left trochanter was a large mass which fitted into the fist, not tender, not movable, and very hard. The motions in the joint were moderately limited, especially abduction and full extension. Dr. Gibney supposed that she had either an old fracture or an old tuberculous healed lesion. The patient had a very great enlargement of the neck of the femur, possibly an old fracture; below that a nodular mass; but it was hard to say whether the deformity was a fracture of 5 years ago or 6 or 8 months ago. Dr. Whitbeck had supposed the case to be sarcoma, but it resembled so closely Dr. Gibney's case that, on examination of that case under exploratory operation, he was inclined to think this case also was an osteitis fibrosa. The girl had gone to Bellevue Hospital for exploratory operation, but it was refused. At present the patient had no symptoms and walked to school; she had not lost weight; was in perfectly good health; the leg showed an inch and a half shortening; the limitation of motion was only moderate.

**Sarcoma of the Clavicle.**—Dr. GIBNEY showed this case. The patient came into the hospital on Dec. 16, 1912, with a tumor involving the inner half of the right clavicle, of three weeks' duration. It had grown very rapidly and was regarded as a sarcoma. The operation by Dr. Coley, who operated at once without waiting for a microscopical confirmation of the diagnosis, consisted of total excision of the clavicle and removal of the tumor. The specimen was a periosteal sarcoma of the class called small, round-celled sarcoma. The boy remained in hospital one week after the removal. It began again to enlarge. Dr. Coley gave toxins and it responded promptly and was apparently cured. The patient was shown before the New York Surgical Society in April. He returned in June with the tumor growing again in the pectoral region and neck, having attained the present proportions, but it did not respond to the toxins or the *x*-ray, except that the growth was held in check, but showed little decrease in size, and he suggested bringing the patient to let Dr. Abbe see if the case was a suitable one for radium. Both Dr. Coley and Dr. Darling thought that the toxins and *x*-ray should be continued, but gave little hope that a cure could be effected. Dr. Coley considered the case inoperable.

Dr. DARLING said that when the patient came to him about a month ago the tumor was the present size. He was given the usual *x*-ray treatment 3 times a week for 4 weeks; during that time it got no larger. By examination it seemed that the sulci were a little deeper and that there was a little more room under the jaw. The cough and the breathing embarrassment became better. Since the use of the toxins the *x*-ray treatment had not been kept up. The tumor had not grown for two months. The *x*-ray treatment was given 3 times a week over a period of 6 weeks, filtered through 3 mm. of aluminum. The erythema dosage was not measured.

Dr. ABBE said this seemed to be a challenge. He did not know whether radium would produce an effect but it would not surprise him. He had known it affect cases of round-celled sarcomata. One enormous one of the mediastinum was checked wherever radium was used, but the case was too massive for a cure to be expected. He was now treating one of the head, a large one, cup-sized, on the top of the skull; it seemed hopeless. The *x*-ray showed perforation of the bone. Much bone tissue was involved. The woman submitted to leveling the lump in the skull to the dura. It was found to have perforated the bone on all sides. He curetted it out and curetted the base of the dura, laid back the flaps and made a heavy application of radium, (Gamma radiated by distance filtration). The woman went home three weeks later in good condition, the wound in the head nearly healed and looking in good shape. The character of the healing was extraordinary considering the infiltration of the bone. The mediastinal tumor he had watched for three years and the boy died this summer. One rib was removed where the tumor had fungated out on both sides of it and the radium plunged deep in the chest. He controlled this mass for a year, but after a year it started again to enlarge. He then gave all the reduction he could, but it was unapproachable. He believed round-celled masses ought to yield. The boy's case presented by Dr. Gibney was external and a very nice example in which to see what effect radium had upon it. It would take a good deal of time and a good deal of radium and a good deal of thought to know how to handle it. As the toxins had failed it might be a fair chance to try this new agent, working in cell structure of this type.

Dr. EWING said that he had been much interested in the structure of this and other similar tumors of bone, which belonged in a definite group of undifferentiated round-celled sarcoma. The origin of these tumors was quite obscure. They probably did not arise from marrow cells and were quite different clinically from any known type of myeloma. He had an impression that they must originate from embryonal cell groups, either superfluous cells that should have gone to form bone or from aberrant cells, as from thyroid, adrenal, or even enamel organ. The prognosis was very unfavorable and he feared that Dr. Abbe had accepted a difficult challenge. These tumors often produced general metastases. The cells did not resemble those of the ordinary hypernephroma.

Dr. BLAKE said it was interesting to note that recurrence was not taking place in the clavicle. The metaplasia of cells could occur before the cells became bony.

**Extensive Wound of the Abdominal Parietes.**—Dr. POLK gave a brief report upon a case shown before the Practitioners' Society six years ago. Subsequent examination has shown that the conditions then attained have been maintained. The case was one of a gun shot wound of the abdomen. All of the left lateral surface of the abdominal wall and the deeper portions down to the intestines were blown off, including the upper crest of the ilium and also the spinous processes in the lower portion of the lumbar region. This accident occurred 9 years ago. The conditions reported to this Society had been thoroughly maintained, so that the man's abdominal surfaces had kept in place and he had been able to live the life of an ordinary normal individual. The great difficulty at the time of operation was to find peritoneal covering for the intestine. The surface to be covered was the region lying between the lower ribs on the left side and the crest of the ilium on the same side and from the outer border of the rectus muscle back to the spinal column. An outer cover was obtained by transplanting the skin and subcutaneous fat adjoining chiefly from below to prevent adhesions between such an unprotected surface as the intestine then presented, and this cover of fat and skin, a peritoneal cover had to be found. The omentum was brought over and stitched into place and served the purpose well. It had proved a successful procedure, and the man was in excellent condition.

Dr. BRANNAN said that he remembered perfectly well seeing the man at the meeting, of whom Dr. Polk spoke. It was a wonderful operation and he was de-

lighted to hear the patient had continued to do so well.

Dr. GIBNEY confirmed Dr. Polk's statement of the excellent condition of the case reported. He was convinced that the patient could give him a good beating at golf.

**Papilloma of the Larynx.**—Dr. ABBE presented this case which he had previously shown a year or two before when there was a complete aphonia. The patient was now perfectly well. She had lost her voice both for singing and speaking, but after one or two months it came back. There was a very large papillomatous mass. Dr. Culbert took it out. It recurred. An application of radium of 30 minutes had effected the cure in eight weeks. The vocal cords showed a perfectly normal condition. Radium did not affect the normal structures and the papillomatous growth yielded readily to it. A second case was that of a woman who had lost her voice and had difficulty in breathing. One or two half hour treatments cured her. The larynx was absolutely clean, no sign of tissue, though the anterior half was a little atrophic and the voice was still husky. He had seen three cases lately and treated for the first time today the third patient to be shown that night. The man worked in the post office and had had an aphenia for five years. He had papillomata of both vocal cords. He had 30 minutes treatment of 100 milligrams which was the correct dose. In two months' time he would be shown. In 8 weeks the vocal cords ought to be clear. These cases were the despair of laryngologists. They reappeared if cut out. Dr. Stickle, a laryngologist of good standing, had treated this man, cutting out the growth and making an absolutely clean excision, but it had reappeared.

Dr. MILLER asked if there were any local reaction.

Dr. BLAKE asked if radium was effective in ordinary papillomata of the hand and if papillomata were contagious.

Dr. EWING said he did not think there was adequate ground for assuming the contagiousness of papillomata of larynx or bladder. In these cases the whole mucosa was predisposed to warty outgrowths and subjected to the same factors of irritation. When a papilloma developed at one point, it was very apt to develop *de novo* at another, especially at points of contact with the original tumor where irritation was intensified. The most active forms of laryngeal papilloma in children might spontaneously regress, if let alone, especially at puberty.

Dr. ABBE said it was a case of extension from one cord creeping round the commissure to the other. Proximity would suggest the reason for both cords being involved. In cases of papillomata on the soles of the feet which had been very painful, they had disappeared with one application of radium. The difference between normal structures' resistance to radium and the resistance of hypertrophic structures was here clearly shown. In the vocal cords the normal structures were never injured. The resistance was perhaps 20 times as great in normal structures. In reply to Dr. Miller he said that there was no local reaction. He had left 100 mm. for half an hour and there was no edema. Replying to Dr. Blake he said that radium was effective against papillomata anywhere on the body,—in the throat or on the tongue. He had had many cases of papillomata of the tongue that looked cancerous and were brought to him as cancer. In some cases the roof of the mouth was covered and they had yielded to one-half or one hour's treatment.

**Vesical Calculus.**—Dr. BANGS presented this case. In 1911 a man, aged 73 years, came to him with the usual symptoms of enlarged prostate and with an infected bladder. In June of 1911, after some preliminary treatment of the bladder to reduce the degree of infection, he performed a suprapubic prostatectomy, and the relief which was given lasted nearly a year. Then symptoms of dysuria with a small amount of retained urine became prominent. Urethrocystoscopy revealed a cicatricial fold of mucous membrane posterior to the internal meatus. This was divided by means of a perineal incision, and was followed by great relief. He then disappeared from view until April of this year, when he appeared with symptoms of stone in the bladder, but he refused to have any examination made. He told Dr. Bangs that he had meandered from one doctor to another and had been to a surgeon who said that he had stone in the bladder. He had been taken into a sanatorium, kept one and a half hours under ether, and when he returned to consciousness, was told that there was no stone in his bladder. The patient said that he bled very freely for a day or two after the examination, and was in bed with fever, painful urination and malaise for nearly two weeks afterwards. He had been compelled to wear a rubber urinal constantly and urination took place every few moments with great pain. He came to see me in September and a diagnosis of stone in the bladder was very easily made. After a few days' preliminary treatment in a sanatorium, litholapexy was performed, removing a stone of about the size of a hen's egg. The first grasping of the stone was a little difficult, but after that no particular difficulty was experienced. Cystoscopy was resorted to three times during the operation, and after the bladder was apparently emptied, the cystoscope revealed a diverticulum in the right lateral wall of the bladder. In this two stones were embedded, one apparently about the size of a hazelnut. The beak of a small lithotrite was insinuated into the semilunar mouth of this diverticulum, and the blades being gently separated, the stones were picked out and dropped into the base of the bladder, the larger one being crushed and both pumped out in the usual manner. On the fourth day, the patient went home and has been receiving occasional treatment for the chronic condition of his bladder, and now holds his urine sometimes six hours.

Dr. BRANNAN asked if the stone had formed after Dr. Bangs had first seen the patient.

Dr. BLAKE asked if the lithotrite was introduced by the aid of the cystoscope.

Dr. BANGS, replying to Dr. Brannan, said it must have formed during 1912, after the operation on the cicatricial fold, because there was no stone in the bladder at that time. From his history it must have begun to form some time in 1912. Replying to Dr. Blake he said no; the cystoscope was used first. The diverticulum and the stones in it were accurately located, and then the lithotrite was carefully introduced, and used as just described.

## NEW YORK ACADEMY OF MEDICINE.

### SECTION ON SURGERY.

*Stated Meeting, Held December* 5, 1913.

DR. LUCIUS W. HOTCHKISS IN THE CHAIR.

**Laryngectomy Combined with Gastrostomy.**—Dr. FRANZ J. A. TOREK presented this communication. He said that the feeding of a patient who had been subjected to an extensive laryngectomy, especially if complicated by a partial resection of the pharynx, was attended by difficulties and dangers. If a permanent tube was introduced through the nose into the esophagus, its constant presence not only caused the patient much inconvenience, but also interfered with the healing of the wound through the fact that the tube, which could not be kept aseptic, rested against the suture in the pharynx. This suture became infected and gave away, and not rarely necrosis resulted. The infection spread downward, and the tracheal stump which had been sutured to the skin might separate from it here and there. It might then happen that even after the patient had successfully rallied from the operation as such, he would aspirate secretions and succumb to a pneumonia. If, on the other hand, the stomach tube was introduced every time the patient was fed, the conditions were, if anything, still worse, for the introduction of the tube, which would be done, at least occasionally, by the nurses, might easily result in perforation of the suture line. Dr. Torek had experienced such a case in which the tube had been pushed through the suture line of the pharynx, and the accident was not noticed until the fluid food which was poured into the tube ran through the dressings into the patient's lap. In the case here presented he had overcome these difficulties in a very simple way. When the laryngectomy had been completed, he performed a gastrostomy according to Witzel's method in order to administer the food through the gastric fistula. The case was a far-advanced one, in which not only the whole pharynx and epiglottis had to be removed, but also the anterior wall of the pharynx had to be resected to the extent of 3 or 4 cm. and a portion of the base of the tongue likewise had to be excised. Under these circumstances the conditions for suturing the pharynx were, of course, very unfavorable. Nevertheless, although on the sixth day the presence of mucus in the wound gave proof that a portion of the wound had given away, the after treatment, particularly as regarded the change of dressings, was so simple that the difference between

this case and former ones was marked. The healing of the wound progressed without any disturbance. The pharynx fistula closed after four and one-half weeks, and the patient could again swallow both fluid and solid food. At the same time the gastrostomy tube was removed, and the gastric fistula closed promptly, without leaking a drop. The addition of a gastrostomy to an extirpation of the larynx did not add very materially to the severity of the operation; for the laryngectomy was done, as he had always performed it, under local anesthesia. In such advanced cases the severe dyspnea forbade operating under general anesthesia, unless one had chosen to perform a preliminary tracheotomy. This, however, one would prefer to avoid in the interests of asepsis. For local anesthesia, Dr. Torek used a one-half per cent. solution of novain with suprarenin, deep injections being made to anesthetize the trachea and larynx and superficial ones for the overlying soft parts. The deep injections were four in number on each side. The first, which was to block the superior laryngeal nerve, was made between the hyoid bone and thyroid cartilage into the thyrohyoid membrane two centimeters from the median line. The incisure of the larynx served as a guide to the median line. The other three injections were made at points further down to reach the posterior part of the larynx and trachea. For these a curved needle was of advantage. One of these was made behind the crycoid cartilage, another below the isthmus, and the lower one in the region of the jugular notch. At least five cc. of the solution was injected at each side, the injection beginning at the deepest spot and being continued, as the needle was drawn forward. The superficial injections were made corresponding to the lines of incision. Dr. Torek said he employed a "T-shaped" incision. The operation itself was made according to Gluck's well-known method, with transverse division of the trachea and suture of the tracheal stump to the skin in the jugulum. When the laryngectomy had been completed, the patient, who now breathed again with perfect ease, could readily take an inhalation narcosis through the tracheal opening for his gastrostomy. Of course, it was also possible to perform the gastrostomy under local anesthesia. This little addition to the technique of laryngectomy would be of good service in many difficult and extensive cases.

Dr. ROBERT T. MORRIS said that in cases in which a part of the esophagus had to be excised and a permanent gastrostomy fistula was desirable, a very good method consisted in turning down two ribbons of skin from the chest wall, suturing them to the stomach, and then dropping the stomach. These ribbons of skin gave epithelial lining face to face, and made a permanent gastric fistula, with little tendency to leakage, because of its angulation at the costal margin.

**Disappearance of Recurrent Mammary Carcinoma after Removal of the Ovaries.**—Dr. FRANZ TOREK said that the remarkable changes, described by Beatson, which the removal of the ovaries brought about in mammary cancer, amounting at times to complete disappearance of the new growth, had also been observed by other surgeons, and about ten years ago the author reported a series of seven cases of his own. As a rule, the improvement, though striking, was but temporary; but in a few cases cures had been claimed. The case presented differed from the others in the fact that, when the ovaries were removed, the patient was not suffering from mammary carcinoma but from recurrent nodes in the skin and subcutaneous connective tissue that had appeared in the neighborhood of the site of an operation for carcinoma of the breast performed about four and a half years previously. The patient was 57 years of age and was operated upon by Dr. Torek for carcinoma of the breast more than five years ago. The large area of skin transplantation visible now gave proof that the excision of skin was very extensive and that we had to deal with an advanced case. A scar extending up into the neck furthermore showed that the cervical glands were removed at the same time. The patient returned to the German Hospital in March, 1913, suffering from fibromyoma of the uterus, and she was placed on the gynecological division in the service of Dr. Gustave Seeligmann. On being examined she called attention to the fact that she had observed a number of nodes growing near the site of the former operation. The case was shown to Dr. Torek and there was seen the well-known characteristic picture of recurrent nodes, some of them larger than a finger tip rather close to the old scar, some smaller ones farther away. The larger ones were slightly reddened, the smaller ones had not changed color. At least a dozen of these were counted. The question came up whether, in the presence of these metastases, it was worth while to operate upon the fibromyoma. On the basis of his former experience with Beatson's operation he expressed himself in favor of it. A panhysterectomy with removal of both ovaries was performed by Dr. Seeligmann, after which the patient made an uninterrupted recovery and left the hospital. We saw nothing more of her until December 3rd, about eight and one-half months after the operation, when a member of the house staff who had seen her, referred her to him. Not a trace of the nodes could be found; they had completely disappeared. In his series of cases formerly reported there was improvement in every one; in one of them the growth disappeared almost completely. The tumors, however, began to grow again after the lapse of six or seven months, sometimes sooner, in every case except one. In that case the tumor which had been firmly fixed to the chest wall became so loose that he performed the radical breast operation about two months after the removal of the ovaries. He saw that patient as late as fifteen months after the operation without any signs of a recurrence that he could detect. She was then suffering from severe headaches, and a few months later he heard that she had died suddenly. He was unable to say whether she died from a metastasis within the skull or from some entirely different ailment. It was possible, therefore, that there was one cured case among his former series. The effect of castration upon mammary carcinoma had always been ascribed to some peculiar relation between the ovaries and the milk glands. The carcinomatous nodes were in the skin and subcutaneous tissue and had not appeared until more than four years after the breast had been removed. It had also been claimed by some that Beatson's operation was most likely to do good in women who were still in their menstrual life. In his former series, however, the best result, the almost complete temporary disappearance of the tumor, occurred in a woman who had passed the menopause. In this respect the present case stood in a rather unique position, for, although she was 57 years old, she menstruated regularly up to the time when her ovaries and uterus were removed. It seemed that the operation of castration in these cases should not be entirely relegated to the heap of therapeutic rubbish where most of them have placed it, but should be remembered in cases where they were unable to do anything better.

**Antiseptics versus Germicides.**—Dr. ROBERT T. MORRIS read this paper and made the point that bacteria and body cells while simple morphologically, were highly organized chemically, and in the course of evolution had come to be peers of each other in questions of warfare. A balance of nature was maintained between bacteria and body cells of higher organisms under normal circumstances. In cases of a wound this balance was temporarily lost and the surgeon was called to give help. When he employed germicides it was essential to remember that any agent capable of injuring the protoplasm of bacteria was capable at the same time of injuring the protoplasm of body cells and of their agents the phagocytes. Antiseptics which were not germicides and which did not injure protoplasm of either organism were for the most part preferable. He said that at the present time an immense amount of damage was done by some surgeons, by nurses and house-staffs of hospitals, and by the laity in general when they employed for wound treatment such germicides as bichloride of mercury, carbolic acid, peroxide of hydrogen, and iodine in cases in which the body cells of the individual would do more effective work when not paralyzed by the injury to their protoplasm. There was a place for the employment of germicides, and this required knowledge and skill on the part of the surgeon. Chinosol had a much greater antiseptic power than bichloride of mercury in the same strength of solution, but was not a germicide. We had been deeply imbued with the ideas of the third era in surgery—the pathological era—in which it was considered essential to destroy bacteria and their products. We were now passing into the fourth era of surgery—the physiological era—in which the fundamental idea was to turn the patient over to himself, to give him home rule in the simplest way which would suffice.

**General Anesthesia by the Ether-Oil Method (per Rectum).**—Dr. JOSEPH E. LUMBARD read this paper. He recalled that Pirogoff in 1847 introduced the method by

which vapor was pumped into the rectum by a hand pump or foot pump. In 1884 Dr. Bull and Dr. Weir of this city tried the method with very discouraging results, namely colicky pains in the intestines, rectal irritation, sloughing, and fatal hemorrhage of the bowel. The method again came before the medical profession in 1904, when Dr. Lehy and Dr. Cunningham of Boston reported about 100 cases in which a modified technique had been used, consisting of preparation of the patient and warming of the vapor. Even with this advance they were not able to avoid the bad results that had attended the use of this method. The new oil-ether method was worked out by Dr. Gwathmey of this city. The ether and oil were mixed, usually in the proportion of one part of oil to three parts of ether; this made an oily solution which prevented colicky pains and irritation of the bowel. The technique was very essential. The bowels must be very empty. They used catharsis and cleansing enemata, but not soapsuds, as the soap would form an emulsion with the oil which would greatly interfere with the action of the ether. A hypodermic of morphine and atropine should be given at least one-half hour before the introduction of the anesthetic solution. In large muscular men and those addicted to alcohol the speaker used hyoscyamine with the morphine and atropine. Dr. Gwathmey used chloretone to anesthetize the bowel before introducing the ether-oil solution. Dr. Lumbard had used chloretone and novocain solution, but did not see the advantage in doing so and had discontinued it. When practical the patient should stand with the catheter in the rectum to completely empty the bowel. He should then be placed on the left side with the knees well drawn up and a small male rubber catheter should be introduced into the rectum. A funnel should be attached to the catheter and the anesthetic solution introduced. The nurse should pinch the catheter so that it would take about five minutes for the solution to run into the rectum. The funnel might then be removed and the catheter clamped and left *in situ*. The patient should be kept very quiet, there being no talking and no handling of the patient until he was well under. It was better that the patient should be in bed. The average amount used was 60 c.c. of olive oil and 180 c.c. of ether. The ether might be detected on the patient's breath in three to ten minutes. The sleeping was followed by a state of anesthesia in ten to twenty minutes. The exciting stage was seldom seen and when present was very slight. The respirations and pulse were more normal with this method than with any other. The eye reflexes and mouth muscles might be active and still the patient be sufficiently relaxed, even for a long abdominal operation. The rectum and part of the large intestine might be slightly distended. In case the patient was too far under the anesthetic, a portion of the solution was withdrawn from the rectum. When not under, more might be added or the rectal anesthesia might be supplemented with a little gas or drop ether. After the operation a rectal tube should be introduced and the remaining anesthetic solution removed. After the bowel had been thoroughly drained two ounces of olive oil were put into the rectum to prevent any possible irritation. The recovery was, generally speaking, apparently prolonged. The waking excitement stage, usually seen in inhalation ether anesthesia, appeared to be absent in the ether-oil rectal method. The anesthesia blended so nicely with the normal sleeping state that it was difficult to tell where one ended and the other began. Dr. Lumbard had used this method in 30 cases, including hysterectomies, gastroenterostomies, goiters, Lane's plating operations, hernias, intestinal obstruction and appendectomies, psoas abscess, removal of bone in esophagus, suspension of the uterus, hypospadias, oophorectomy, appendicitis, cleft palate, cholecystitis, etc. The disadvantages of the method were that it required considerable time to prepare the rectum and for the preliminary hynodermic medication, the uncertainty of the length of the anesthetic stage, and the prolonged sleep. The prolonged sleep might be a distinct advantage to the patient, but the relatives did not always think so. The method had distinct advantages in head and neck operations; there was no mucous secretion about the air passages and respiration and pulse were normal nearly, and it did away with a mask that might be unclean. At present the method was only in the experimental stage, but it was safe to extend its use in selected cases. It was well worth trying in head and neck operations.

Dr. MORRIS said that after hearing the papers of Dr. Gwathmey and of Dr. Crile a few days ago he arranged a series of eight cases at a clinic at the Post-Graduate Hospital. In two of these the Gwathmey method was employed in detail, in two others the Crile method was followed in detail, and in the remaining cases older methods of anesthesia were employed. Notes were made in a comparative way upon the behavior of these patients. The cases in which oil-ether anesthesia had been employed by rectum, according to the Gwathmey method were one of ovarian cyst and one of acute appendicitis. Dr. Morris was particularly struck by the complete relaxation of the abdominal wall in these two cases, which was quite remarkable, the abdominal wall becoming entirely relaxed while the head reflexes of the patients were still quite active. It was his opinion that the method would prove to be extremely valuable after its various phases had been worked out fully and we have come to learn its limitations and objectionable features.

## SOUTHERN SURGICAL AND GYNECOLOGICAL ASSOCIATION.

*Twenty-sixth Annual Session, Held at Atlanta, Georgia, December 16, 17, and 18, 1913.*

THE PRESIDENT, DR. JOHN YOUNG BROWN, ST. LOUIS, MISSOURI, IN THE CHAIR.

(*Continued from page 222.*)

**Surgery of the Ileocecal Coil.**—Dr. FRANCIS REDER of St. Louis, Mo., maintained that the most important feature for successful surgery of the intestinal tract was an early diagnosis. The great danger following a successful resection of the ileocecal coil with immediate restitution of the canal lay in the secondary changes which had taken place in the intestinal walls, induced by the disease for which the operation was undertaken. The complete atony of the bowel so often present activated various infective processes generated by the pent-up bacteria. Whenever the virulent contents of the bowel became stagnant at the site of suture, the suture frequently yielded and a peritonitis usually incompatible with life resulted. One of Dr. Reder's cases bore the gravest aspect, developed a fecal fistula on the fifth day after operation and recovered. This happy termination occurred after a patient had died by the ideal method on the ninth day following the operation. It demonstrated to him the fact that a vent became almost a necessary adjunct to this operative procedure. Having had two recoveries with the ideal operative measure that proved in no way more severe than a simple appendectomy, he at no time had underestimated the choice of an operation for the resection of the ileocecal coil. In his last two cases he had successfully employed a technique that carried with it the feature of an artificial anus, but in a modified form. The advantage of this technique was a vent that would not require risky operative measures for its successful closure. An incision was made through the outer edge of the right rectus muscle. Ablation of the tumor and the removal of the mesenteric glands were carried out. The division of the ascending colon and the ileum was an important feature. Inasmuch as cecal growths usually embodied considerable of the ascending colon, the hepatic flexure might not be far distant. It was of some advantage to make resection of the colon at or beyond the hepatic flexure. The division of the ileum should be such as to give the bowel the necessary latitude to be brought without tension in contact with the colon, near the point of resection. At least six inches of the ileum should be sacrificed. The end of the colon was closed with suture in the accepted manner. The end of the ileum was closed temporarily with a basting stitch so as to avoid spilling any of its infective contents while the operation was in progress. A lateral anastomosis with an opening not less than three inches was performed. With a suture conveniently placed through the serosa of the bowel, the end of the resected colon was secured to the abdominal wall as far laterally as could be done to leave tension upon the line of anastomosis and possibly anticipate any future displacement of the gut. After the anastomosis was completed the free end of the ileum was drawn out of the abdomen, was sutured to the parietal peritoneum of the wound into its uppermost corner away from any viscus that might be liable to get caught at the point of fixation, and the abdominal wound was closed. If a more advantageous implantation of the ileal end could be made through a small secondary abdominal incision, this should be done, and the primary

incision closed completely. Of the ileocecal resections there had been three deaths following the ideal method, and one in which an artificial anus was made. There had been two recoveries from the ideal method, one following an artificial anus, and two by his method. One patient developed a fecal fistula five days after operation.

**Cyst of the Appendix.**—Dr. Rudolph Matas of New Orleans reported and exhibited with lantern slides a specimen of a rare, retroperitoneal, multilocular, retrocecal cyst of the appendix veriformis of large size, weighing 1,582 gms. (over 52.7 oz.) which contained a gelatinous, coagulable, myxoid fluid of variable color and consistency. It measured 47.5 cm. in circumference (18¾ inches) around its longest diameter; 17½ cm. in breadth (7 inches), 10 cm. in thickness (4 in.), with a perimeter of 56 cm. (22 inches). It was in no sense a retention cyst or hydrops, as the appendix was quite distinct and separate, though intimately attached to the mass. Its origin was doubtful and obscure. It was evidently a connective tissue sac with multiple compartments lined with endothelium. Probably an outgrowth of some embryologic relic connected with the mesentery; possibly a development of an original lymphangioma cavernosum of the mesentery. The mass had been removed from a young man, aged 25 years, who had recovered uneventfully after the intervention.

**Treatment of Trigeminal Neuralgia by Deep Intraneural Injections for Anesthetic and Therapeutic Purposes.**—Dr. Rudolph Matas of New Orleans considered the subject from the double point of view: (1) Analgesia of the territory sensitized by the trigeminus for purely surgical purposes; (2) analgesia of the trigeminus for the relief of neuralgia. He recalled his early pioneer efforts as far back as 1889, when working with regional anesthesia, he succeeded in anesthetizing the second division of the fifth nerve at both foramina rotunda by injecting the trunk of the nerve at its exit from the foramen, and obtained sufficient anesthesia to permit of a complete excision of both upper maxillæ for an extensive carcinoma of the upper jaw and palate. Both upper maxillæ were exercised at the same sitting. Prior to that time he had performed several operations on the jaws by reaching the nerve trunk at the foramen rotundum through the inframalar route which has since been associated with his name, and is practically the route subsequently adopted by Schlosser for the introduction of alcohol into the nerve at its exit from the foramen. But in this particular instance he injected the nerve at the foramen rotundum through the orbit by the route of the sphenomaxillary fissures, filling the sphenopalatine fossa with a cocaine solution so as to obtain a complete anesthesia of the second division and Meckel's ganglion with all its branches. This was the route that by a mistaken impression was credited to Payr and which Härtel had recently extolled as the most direct and satisfactory way of reaching the foramen ovale. He also resorted to the lateral inframalar route, to reach the foramen ovale and thus controlled, by the two methods, the area supplied by the second and third divisions. The results obtained in several cases of resection of the lower jaw for malignant diseases were exhibited in lantern slides. The results in all these cases were quite satisfactory from the analgesic and operative point of view. Since the introduction of intraneural injections of osmic acid by Neuber, and especially of alcohol by Schlosser in 1907, he had devoted special attention to the technique of injecting the nerve trunks for the relief of tic douloureux. More recently, however, he had gone a step further by attacking the Gasserian ganglion itself. He reviewed the various routes advocated by Schlosser, Oswal, Wright, Levy and Boudouin, Sicard, Taptas, Braun, Offerhaus, and Härtel, and especially his experience in the last method which he had practised considerably during the past year with his assistant, Dr. U. Maes, who, by a large and constant practice on the cadaver had acquired unusual expertness in this rather difficult procedure. He concluded that in the hands of an expert, careful, and experienced surgeon, the anesthesia of the trunks of the trigeminus at the basal foramina, more particularly the second and third divisions, and the Gasserian ganglion itself, was a perfectly feasible and practical procedure which could render decided service in the surgery of the face. It would also permit of a satisfactory, safe, and certain relief of trigeminal neuralgia, especially when the exact localization of the nerve or the ganglion was determined by obtaining a complete and demonstrable anesthesia with novocain-adrenalin, before the alcohol injection was made. The injection of the ganglion through the foramen ovale by the Härtel route was not free from fallacies and dangers, but taken as a whole, it constituted a decided advance in the regional anesthesia of the face.

**Cholecystectomy vs. Cholecystostomy, and a Method of Overcoming the Special Risks Attending Common-Duct Operations.**—Dr. George W. Crile of Cleveland, O., drew the following conclusions from the evidence presented in his own cases: (1) Considering all the consequences of infection, cholecystectomy in the type of cases indicated showed a morbidity and a mortality lower than cholecystostomy. In these cases the clinical results of cholecystectomy were good; while in unsuitable cases cholecystostomy was followed by recurrent cholecystitis. (2) He had seen no adverse effects from cholecystectomy, provided that the division was made at the beginning of the cystic duct; that no gall-bladder tissue was left, and that the division did not at all encroach on the common duct. This technique could be readily carried out. (3) If acute infection was present then in most cases cholecystostomy should be first performed, followed, if required, by a later cholecystectomy. (4) If the gall-bladder and the cystic duct were approximately normal, then the gall-bladder was left, cholecystostomy being the operation of choice. If the gall-bladder was thick, contained much scar tissue, was shrunken, showed chronic infection of the musculature, was much impaired, if the cystic duct was partially or completely strictured, or if a stone was impacted in the duct, then cholecystectomy was made. (5) All gall-bladder operations, and especially common duct operations, might be performed with a minimum of post-operative shock and discomfort by thorough nerve blocking with novocain and quinine and urea hydrochloride by sharp dissection and gentle manipulation. (6) The principal causes of the higher mortality in common duct operations were the damage done to the nerve supply of the liver, and the loss of bile salts. The sharp knife dissection and the clean cut ample incision into the common duct, with the consequent minimum nerve injury, the immediate closure in suitable cases of common duct by suture will immensely improve the morbidity and the mortality following this operation. (7) The mortality rate in the 656 records studied for the purposes of this paper was 6 2/5 per cent. This rate, as well as the post-operative morbidity would be decreased with the application of the technical procedure described herein.

**Infraction of the Second Metatarsal Bone—A Typical Injury.**—Dr. Albert H. Freiberg of Cincinnati reported six cases in which the patients presented themselves because of pain at the metatarso phalangeal joint of the second toe. In these cases the *x*-ray examination showed that there had been an infraction of the distal end of the second metatarsal bone. In three of the cases there were loose bodies at the joint and in two of these cases they had to be removed in order to give relief. No case was seen less than four weeks after the injury, and in two cases there was no recollection of the injury. The trauma was always a slight one, occurring at tennis in three of the cases and consisting merely of a false step. These cases had probably often failed of recognition because of the similarity of the symptoms with those of the so-called "anterior flat foot." Aside from the röntgenogram, the diagnostic features were the traumatic origin, thickening, and marked tenderness of the second metatarso phalangeal joint and grating on passive movement if loose bodies were present. The treatment was purely mechanical save when loose bodies indicated arthrotomy for their removal either because of their size or number. In one case permanent relief without operation resulted even though a loose body 2 mm. in diameter was present. Not a little interest attached to the mechanism which took place by this injury to the foot. Under normal circumstances the second metatarsal bone was slightly longer than the first. In the presence of a diminished power of toe flexion and especially of the great toe, it was apparent that forcible impact of the ball of the foot against the ground not sufficiently guarded by the flexor power of the toes would cause the distal end of the second metatarsal to bear the brunt of the blow. It seemed likely that we had here the explanation of the mechanism of this injury.

**The Open Treatment of Fractures.**— Dr. George A. Hendon of Louisville, Ky., stated the indications for the use of the plate were as follows: (1) In fractures that could not be reduced by ordinary manipulations. Such situations developed frequently in impacted fractures and in fractures where one fragment was very much shorter than the other and overriding existed. (2) Fractures that were difficult to maintain in reduction, as in those where a process of bone was broken off.

For example, a condyle of the humerus or the olecranon, and cases where the muscular attachment was so strong and the lines of force so directed as to pull the fragments apart, as in the femur. (3) Delayed union. (4) Where good cosmetic effects were especially desirable, as in the clavicle or forearm of young women. (5) In fractures communicating with a joint wherein imperfect alignment or overproduction of callus was likely to seriously interfere with function. The mortality in his own work comprised one death which occurred twenty-four hours after the operation, but which could fairly have been attributed to associated injuries. J. B. Roberts collected and reported nine deaths following operations. Blake did not record a death in one hundred and six operations. Bartlett recorded two deaths in eighty cases. Darrach in one hundred and four cases reported had no record of death. He felt assured, therefore, that the mortality of the operation *per se* was a negligible quantity, especially if the operation was resorted to in the recent period after the fracture and performed under the proper restrictions.

**Fracture of the Neck of the Femur.**— Dr. JAMES E. MOORE of Minneapolis, Minn., stated that the fact that bony union after fracture of the neck of the femur could be secured had been demonstrated repeatedly, but had not yet been accepted by the profession. The fact that fracture of the neck of the femur frequently occurred in children had not been generally recognized. The indications in treatment of fracture of the neck of the femur were the same as in other fractures, viz., to bring the fragments into apposition and hold them there. The method advocated in this paper secured this opposition where the old methods failed. Whether the theory of the newer treatments was correct or not was immaterial, because the fact was that they produced the desired results. Older methods failed to control the shorter fragments; the new methods succeeded. The principle of the new method was that by adding a side pull to Buck's extension the resultant of the two pulls was a pull outward in the long axis of the neck of the femur. This rendered the capsule of the joint taut, and brought the floating short fragment into contact with the longer one. This side pull was brought to bear upon the inner side of the upper end of the thigh by means of weight and pulley, the amount of weight being about one-third of that at the foot of the bed. In a child a healthy joint might be fixed almost indefinitely without danger of ankylosis, but in an adult ankylosis was a real danger following fixation. In the modern treatment the knee could be flexed and the patient allowed to sit up in bed without interfering with the position of the fragments. In all the writer's experience with the old methods he had but one case in which the result was approximately satisfactory. After the new method all but two had been satisfactory; in one of those the patient developed rheumatism, and the other lacked the power to produce osteoblasts. A satisfactory result was secured in one patient sixty-six years of age, when the treatment was not applied until four weeks after the accident. The surgeon who refused to accept the testimony of those who had tried this method was doing himself and his patrons an injustice. When non-union occurred because of faulty treatment there was still hope for the patient through operation, but it was useless to operate upon patients who had no bone producing power. Whitman's method of extreme abduction and retention by plaster-of-Paris would secure bony union, and was undoubtedly the best method for the treatment of children, but it was neither as comfortable nor as convenient as the "anatomic" method for adults.

**Open Operation for the Proper Fixation and Repair of Fractures with Lantern Slide Demonstration.**—Dr. FRANK MARTIN of Baltimore, Md., stated that due credit should be given to Mr. Lane for the enormous advance he had made in this domain of surgery. His contributions should be regarded as epoch-making in the treatment of skeleton injuries. His fixation device for correction of skeleton deformities was the best we had at the present day. His views were that every known method should be made use of for the correction of fractures without operation, and only in failures to get good results after every good method had been tried were we justified in employing the open operation. If failure had occurred and there was faulty position, then we should correct the skeleton injury whatever it was by open operation except in Colles' fracture and fractures in young children, which injuries should be corrected by careful knowledge of reduction methods and the proper application of splints. Open fractures should be cleansed and operated upon as soon after their occurrence as possible. The use of the plate gave infinitely better results and more speedy convalescence without the accompanying stiffening of the adjacent joints. It was distinctly a major operation and should only be done by an experienced surgeon. The four chief indications for the open operation were as follows: (1) If, after repeated attempts, if necessary, the bone could not be placed in apposition or could not be maintained in apposition, the open operation should be resorted to. (2) If, after reduction of fractures of long bones, no crepitus could be elicited, you should be suspicious of interposed soft parts and resort to the operation in order to prevent a delayed nonunion which produced an unnecessary long period of convalescence. (3) All open fractures as a rule should be cleansed, fixed, and if necessary drained. (4) All cases of delayed non-union and all cases of vicious union should be subjected to immediate operation; no efforts at reduction without operation should be employed.

(*To be continued.*)

# State Medical Licensing Boards.

## STATE BOARD EXAMINATION QUESTIONS.

STATE BOARD OF MEDICAL EXAMINERS FOR THE STATE OF TEXAS.

*Austin, June 24-26, 1913.*

(*Concluded from page 184.*)

### SURGERY.

1. What are the symptoms of air embolism? Give treatment. In what region are surgical operations most liable to be followed by this condition?
2. Give the symptoms of simple, compound, and compound comminuted fracture, and treatment of each condition of tibia and fibula.
3. Give symptoms of patient indicating tracheotomy; then intubation, and describe fully each operation.
4. Diagnose an infective exudate of the pericardial sac, beyond controversy, and state how you are going to relieve this condition.
5. Differentiate tuberculous and syphilitic synovitis.
6. Give structural changes that induce, symptoms of, and describe in detail, Bassini's operation for strangulated, oblique inguinal hernia.
7. Differentiate concussion, compression, and congestion of the brain.
8. Give differential diagnosis of pelvic peritonitis and impaction of feces.
9. Give signs and symptoms of cervical rib, and state how cervical rib produces signs and symptoms.
10. How should a dissecting wound and attendant blood poisoning be treated? What is rational treatment of suppurative abscess from its initial symptoms? Give symptoms and treatment of psoas abscess, and state with what condition it may be confused.

### HYGIENE.

1. What are the preventable diseases by which the average human life could be prolonged?
2. How would you disinfect a room after occupancy by a patient with an infectious disease?
3. What methods do you adopt to prevent infection during labor, and what instructions do you give for the care of the mother and child during the lying-in period?
4. What are the parasitic diseases that may be caused by meat insufficiently cooked?
5. What are the principal pathogenic bacteria found in milk?
6. How would you test milk for impurities? for adulterants?
7. What is the difference in appearance between healthy and spoiled meat?
8. Give five reasons from a hygienic standpoint why the fly should be swatted.
9. In what ways is meat adulterated or "doctored."
10. What amount of floor-space should be allowed in a school-room for each child? Give proper height of ceilings of school-rooms, and what should be least window area in proportion to size of window.

### MEDICAL JURISPRUDENCE.

1. For medicolegal purposes "mortuary law" is classified into four divisions; name them.

2. What do you understand by the term "suggillation"; give its medicolegal significance; describe a post-mortem in a medicolegal case.

3. Give methods employed in the identification of blood stains and examination of blood; differentiate between human and animal blood.

4. Give four common causes of death from wounds; differentiate between punctured and penetrating wounds inflicted before and after death.

5. Differentiate post-mortem findings of carbonic-acid gas and sulphureted hydrogen gas.

6. Name seven forms of medicolegal pregnancy; give medicolegal importance of the uterus in the dead.

7. Give conditions or grounds warranting "justifiable abortion"; give the necessary safeguards to be observed, so as not to be held responsible for assault and criminal abortion.

8. In the consideration of insanity and its relations to the law, give the two important questions to be determined; give distinction between intellectual and moral insanity.

9. Give four classifications or divisions of monomania and define each.

10. As applied to life insurance, what is meant by "material concealment?" Give relations of suicide to life insurance.

## ANSWERS.

### SURGERY.

1. *Air embolism* is characterized by a sudden, hissing noise as the air enters a vein; there are dyspnea, syncope, and collapse. *Treatment* consists of immediate pressure on the part; the head should be lowered, the vein must be picked up and ligated; afterward artificial respiration and stimulation may be necessary. It most frequently occurs in surgical operations in the neck or axilla.

2. In a *simple fracture*, there is history of the injury, disability, deformity, pain, false point of motion, and possibly crepitus; in *compound* fracture, in addition to the above there is an open wound leading down to the site of fracture; in *comminuted* fracture, the bone or bones are broken into small pieces. Constitutional effects (due to hemorrhage, shock, sepsis, or other complications) may follow. *Treatment of simple* fracture: First of all, prevent it from becoming compound, then reduce it, coapt the edges of the broken bone, immobilize the parts, and attend to the general condition of the patient. In *compound* fractures: Give an anesthetic, thoroughly asepticize the parts, stop the hemorrhage, remove loose fragments of bone, fix the bones, drain, and immobilize; the wound wants careful antiseptic treatment. The leg must be flexed on the thigh to aid in reducing the fracture, and it may be necessary to cut the tendo Achillis. Splints will be necessary.

3. Tracheotomy. *Indications:* Obstruction to the respiration (diphtheria, foreign bodies or stenosis, edema of the glottis, laryngeal paralysis, tumors) and as a preliminary to some other operations. *The operation:* "The patient is placed on the back with a narrow pillow under the neck. Chloroform or cocaine can be used as anesthetics. An incision, one and a half inches long, is made downward from the cricoid cartilage, keeping strictly in the mid-line. The incision is deepened till the tracheal rings and isthmus are exposed. Enlarged veins give trouble during this stage if there is dyspnea. A director-hood is thrust into the trachea, and the point of a knife is slid along the groove to open the trachea from below upward. The patient is allowed to cough for a few minutes while the wound is kept open with dilating forceps; then the tube is tied in." (*Aids to Surgery.*)

Intubation. *Indications:* Diphtheria, stenosis of larynx, and edema of the glottis. *The operation:* "The child is wrapped in a blanket to control the arms and legs, and is held upright by a nurse seated in a chair, while an assistant holds the head upon the nurse's left shoulder and prevents the mouth gag from slipping. A long piece of silk is passed through the small opening in the upper part of the tube, the tube is fastened to the introducer, and the silk looped around the little finger. The left index finger is passed into the throat, and lifts the epiglottis while the tube is passed along it into the glottis. The left index finger is then made to press upon the head of the tube which is released by pulling the trigger on the introducer, which is then withdrawn. When one is assured that the tube is in the right place and that the symptoms are relieved, the silk loop may be cut and withdrawn while the finger is again made to press down on the tube. If the tube is coughed up, it is too small and the next larger size should be introduced. In cases of diphtheria the membrane may be pushed before the tube and cause asphyxia, which, if not immediately relieved by expulsion of the membrane after the tube has been pulled out by the string, will demand tracheotomy, hence instruments for this operation should always be at hand. The patient speaks in a whisper, and is apt to inhale food during deglutition, hence feeding should be *per rectum* or by nasal tube, although some advise feeding with the head lower than the body, or the giving of semi-solids, which will more easily pass over the glottis. The tube remains in place several days, and is then removed with the child in the same position as for introduction, by passing the left index finger down to the tube and slipping the point of the extractor into its opening, the tube being engaged by pressing the spring on the shank of the extractor." (Stewart's *Manual of Surgery.*)

4. An aspirator is passed into the pericardial sac, being introduced in the fifth intercostal space quite close to the sternum and thrust backward and inward; the fluid withdrawn will be found to contain pus. The condition is relieved by drainage following aspiration.

5. "*Syphilitic synovitis* may occur in the early secondary period, when effusion is slight, if present at all, and the condition merely gives rise to slight pain. Diagnosis is only arrived at by the recognition of other signs of secondary syphilis. A different type of syphilitic synovitis occurs late in the disease, gives rise to but little pain, but causes a diffuse swelling of the synovial membrane, which in one or two places may have the doughy feeling of a softening gumma. The condition may occur in the congenital as well as in the acquired form of syphilis, so that evidences of congenital syphilis, such as peg-teeth or interstitial keratitis, should be looked for, as well as the circular scars of the characteristic tongue of the acquired variety."

"*Tuberculous synovitis* is practically confined to the earlier years of life, but a tuberculous synovitis of advanced years does occur, and in these cases the wrist-joint is that most often affected. The leading features in the disease are swelling of the joint (the swelling being due to a thickening of the synovial membrane, which feels tough and elastic to the touch), deformity, and wasting of the muscles. Pain is often an early symptom, and it may be referred along the course of the connections of the nerves supplying the joint, as in the well-known instance of pain felt in the knee-joint in hip-joint disease. The pains may not be severe except on movement, but if erosion of the cartilages of the joint occur, characteristic 'starting pains'—*i.e.* pains occurring at night just as the patient is dropping off to sleep—may be complained of." (*Aids to Surgical Diagnosis.*)

6. *Symptoms of strangulated hernia: General.*—"Severe pain comes on suddenly after some effort, at first referred to the umbilicus, and subsequently to the site of the hernia. This is accompanied by some shock. The pulse is weak, and, though slow at first, becomes rapid; the skin is cold and clammy; vomiting occurs, and soon becomes frequent and fecal-smelling. Constipation is complete, though both feces and flatus may be passed at first from the lower bowel. The patient generally becomes exhausted from the vomiting and inability to take food. When gangrene occurs the temperature becomes subnormal, the pulse very rapid and weak, and the patient dies of toxemia from the general peritonitis which follows gangrene. *Local.*—A tumor forms at one of the hernial sites; or more often the patient has been the subject of a hernia, which he now finds to be irreducible, tense, tender, and without impulse on coughing. If allowed to persist the sac and coverings become gangrenous."

*Treatment* is taxis or operation. "Operative treatment should be undertaken at once when gentle taxis has failed. An incision is made over the sac, which is then opened. There is usually fluid in the sac, so there is no danger of wounding the gut. The fluid is washed away, then the cause of strangulation is made out, and a hernia knife guided up to it by a finger or broad hernia director. The constriction is nicked in one or two places and the gut is drawn down so that the site of strangulation may be examined. Omentum is ligatured and removed. According to the condition of the intestine the further treatment differs. (1) If the gut, though black, has not lost its polish, it is reduced by gently compressing it to remove the edema. (2) If gangrene is suspected, the strangulated portions must be resected, and end-to-end union established. (3) If the gut is undoubtedly gangrenous, one of two methods must be adopted: (*a*) If the patient is profoundly collapsed and will not bear a prolonged operation, an artificial anus is established by dividing the constriction outside the sac, so as not to open the peritoneal

cavity. The loop of bowel is then opened to give free exit to the feces. Most of the cases which have to be treated in this way are so bad before treatment is commenced that a fatal termination must be expected. (*b*) If the patient can possibly stand it, immediate resection gives the best chance, and with Murphy's button or a bobbin much time can be saved. A radical cure is advisable after the strangulation has been relieved, unless the patient's condition contraindicates it. Liquid food is given at the end of twenty-four hours, and the bowels need not be disturbed for five or six days, when castor oil may be given." (*Aids to Surgery.*)

7.

| CONCUSSION OF THE BRAIN. | COMPRESSION OF THE BRAIN. |
|---|---|
| Unconsciousness is incomplete; patient can be made to answer, though it may be briefly, and in simple words. | Complete unconsciousness; may scream into patient's ear at the top of the voice, but will receive no answer. |
| Special senses, though greatly blunted, are not abolished. | Special senses entirely suspended. |
| Power of movement not destroyed; if the position of a limb be changed the patient will resist or bring it immediately into the original position. | Complete or partial paralysis; in most cases hemiplegia. |
| Respiration is quiet and feeble. | Respiration full and noisy. |
| Pulse feeble, frequent, and intermittent. | Pulse full and slow, and sometimes laboring. |
| The stomach sickens and rejects its contents. | The stomach is insensible to any impression; no nausea or vomiting. |
| The feces may be discharged incontinently, as may also the urine, though not usually. | Bowels are torpid, and the bladder incapable of emptying itself, though the urine may escape by overflow. |
| Deglutition little impaired. | Deglutition difficult or impossible. |
| Pupils variable, though generally contracted; the eyelids somewhat open. | Pupils variable, though generally much dilated, and the eyelids closed. |
| Temperature of the body less than natural. | Temperature almost natural, a little below the normal standard. |

(From Treves' *Manual of Surgery.*)

*Congestion of the brain* is characterized by severe throbbing headache, fever, noises in the ears, full pulse, flushed face, great mental excitement, and sometimes coma.

8. In *fecal impaction,* there is a history of long continued and increasing constipation, feeling of languor and depression, anorexia; the abdomen becomes distended gradually, and the symptoms develop slowly; pain comes on gradually, and later becomes continuous; there is usually a tumor in sigmoid flexure or cecum, it is doughy and firm; constipation is absolute.

In *peritonitis,* the pain is severe and comes on suddenly, there is some fever, tenderness is pronounced, the abdomen is firm and rigid, and no tumor can be felt.

9. A *cervical rib* may not give any signs or symptoms; when such are present they are due to pressure on brachial plexus or some blood-vessel. It may cause subclavian aneurysm, neuritis, or gangrene of hand. There may be pain, weakness of the arm, trophic disturbances, or obliteration of the pulse. The *x*-rays confirm the diagnosis.

10. "When a wound is inflicted while dissecting, wash it under a strong stream of water, squeeze, and suck it to make the blood run, lay it open if it be a puncture, paint it with pure carbolic acid, and dress it with iodoform and hot antiseptic fomentations. Trouble, of course, may follow; often it is only local and a small abscess forms. It should be treated by hot antiseptic fomentations and early incision. Occasionally lymphangitis arises, adjacent glands inflame, and constitutional symptoms arise. It is rarely that true septicemia or pyemia arises unless the wound was inflicted while making a post-mortem upon a person dead of septicemia or while operating on a septic focus. If glands enlarge and soften it may be necessary to remove them surgically."—(De Costa's *Surgery.*)

In the early stages of an abscess, when suppuration is doubtful, treat as if it were an acute inflammation. When pus is evidently present, incise freely, open secondary loculi, swab out the pus, do not curette, irrigate with antiseptics and drain.

*Symptoms of psoas abscess:* "There may be none, old unsuspected psoas abscess being often found at the autopsy. Early symptoms depend upon irritation of the lumbar nerve roots—namely, sciatica, cruralgia, or neuralgia of the anterior crural. Aching across the hip and back and the base of the sacrum; cramp, and at times paralysis. Inability to extend the thigh. Children merely complain of a pain down the thigh, and always carry it flexed. Deep pressure in the abdomen, along the semilunar line, reveals a vertical, sausage-shaped, tender, fluctuating, elastic tumor (mistaken for loaded bowels, but which does not roll from under the fingers). It may or may not reach Poupart's ligament and may be accompanied by a tumor of similar character in the iliac fossa. The abscess may run its course without any subjective symptoms, the extra abdominal tumor first attracting attention. When extra abdominal the usual physical signs show it to be abscess; and the impulse on coughing that it has intraabdominal connection; combined pressure above Poupart's ligament and over the tumor in, e. g. the thigh, reveals fluctuation. Psoas abscess is most likely to be overlooked when symptoms of spinal or sacroiliac disease are not coexistent."—(Heath's *Dictionary of Surgery.*)

*Psoas abscess may be confused with:* Loaded intestine, hernia, bubo, and abscess near or connected with the vermiform appendix.

HYGIENE.

1. *Preventable diseases:* Anthrax, cerebrospinal meningitis, cholera, diphtheria, erysipelas, gonorrhea, hydrophobia, influenza, leprosy, malaria, measles, mumps, plague, pneumonia, scarlet fever, smallpox, syphilis, tetanus, tuberculosis, typhoid, typhus, yellow fever, hook-worm disease.

2. To *fumigate by sulphur dioxide:* For each 1,000 cubic feet of space, three pounds of sulphur are burned, care being taken to prevent accidents. In all cases all apertures and crevices of the room should be closed, all closets, drawers, or other receptacles opened; and after the fumigation the room should be well ventilated and thoroughly cleansed with a solution of corrosive sublimate.

3. The majority of puerperal infections are traceable to the insertion of pathogenic germs by the examining finger or hand of the physician, who in the course of his daily work may have touched the dried sputum of diphtheria, the desquamated skin of scarlet fever, suppurating wounds, erysipelatous surfaces, and other virulent infectious material. Even if the examining hand is protected by a sterile glove, pathogenic bacteria may be carried into the vagina from the vulva, if there is a faulty technique in making the examination. The hands of the nurse or other attendants may be the agents that deposit bacteria in the vagina or upon the vulvar orifice. The implements used in and about the parturient canal, an atmosphere laden with dust or vitiated by foul unhygienic conditions, and the water used to wash and douche the patient may carry disease germs to the parturient woman and may introduce them into the genital canal. The bed clothing, the personal clothing, the mattress, the vulvar pads, the material used to cleanse the vulva (rags, sponges, cotton, cloths), may each and all be sources of infection. Putrescible material retained within the genital canal (especially within the uterine cavity) attracts the innumerable and ubiquitous saprophytes and their spores, with which the purest atmosphere swarms. The development of these bodies in a situation most favorable to their growth and active propagation may easily result in a toxemia, if not in actual invasion of the body by pathogenic germs. Coitus in the last weeks of pregnancy is said to be a source of infection of the genitalia in exceptional cases, by carrying pathogenic bacteria into the vagina. Finally, a certain proportion of cases may be traced to autoinfection—that it, to pathogenic germs resident in the body, and not introduced from without during or after labor." (Hirst's *Obstetrics.*)

Infection during labor is prevented by the strictest personal asepsis, by careful cleansing of the external genitals of the patient, and by infrequency of vaginal examinations.

*Care of mother during puerperium: "During the first week* the patient keeps the bed, but after the first few hours she has considerable license. She may assume the sitting or half sitting posture to take her meals and to nurse the baby, and, if necessary, for evacuation of the bladder and rectum. She should assume the lateroprone posture both right and left, several times a day, and lie upon her abdomen for at least an hour daily. Frequent change of position favors uterine drainage and massages the uterine supports. *During the second week* she has greater liberty, while the greater part of her time is spent on the bed or lounge. She may sit up for her meals, to urinate, and for bowel movements, and she should spend at least half an hour, twice daily, in abdominal and leg exercises to keep up her muscular tone. *The third week*—
